Quebec, Que.—Tenders, addressed to the secretary-treasurer of the Municipality of Halifax-South, will be received until March 25, for the construction of two highway bridges, with steel superstructure, concrete abutments, approaches, etc., on the Frontier and Pigeon Rivers (ten arpents distant) in the Parish of St. Ferdinand d'Halifax, Megantic County. Plans and specifications may be examined at the Council's Office and at the Department of Public Works and Labor, Quebec.

Ottawa, Ont. Under direction of the Hon. the Minister of Militia and Defence the following old stores are for sale by public tender: Metal, old brass, 94 lbs.; copper, 24 lbs.; iron cast, 5,640 lbs.; iron galvanized, 234 lbs.; iron, wrought, 735 lbs.; lead, 870 lbs.; steel files, 26 lbs.; steel scrap, 1,105 lbs.; tin, 96 lbs. The above mentioned stores may be seen on application to the Senior Ordnance Officer, Winnipeg. Sealed tenders for the purchase of any or all of the lots addressed to the above mentioned officer will be received until March 20, 1917. Eugene Fiset, Deputy Minister, Militia and Defence, Ottawa.

BUILDINGS

Three Rivers, Que.—Lymburners, Ltd., of Montreal, are building a munitions factory here.

Windsor, Ont.—The Heintzman Piano Co. will make an addition to their building here. T. C. Pennington Labelle is the architect.

Montreal, Que.—The Steel Company of Canada has obtained a permit to erect a building on Notre Dame Street West, St. Joseph's Ward, to cost $1,200.

Kingston, Ont.—The Chancellor of Queen's University, Dr. James Douglas, of New York, has agreed to give $100,000 towards a fund to develop the Kingston General Hospital into a capacious modern institution.

Montreal, Que.—Permits were taken out in February for the erection of buildings to a total of $3,588,600 and permits were taken out in the same month to make repairs to cost $43,965. There was a falling off in the number and value of permits taken out in the last week of the month.

Toronto, Ont.—At a recent session of the Etobicoke Township Council the trustees of School Sections No. 3, Etobicoke, and No. 24, York, both in Lambton, asked for a grant of $4,000 to complete their school buildings. The council approved of the request, and debentures will likely be issued for that amount.

Winnipeg, Man.—T. H. Johnson, Minister of Public Works, announced in the Legislature on March 5 that the contract for the completion of the Parliament Buildings would be let to the J. McDiarmid Construction Co., at $1,785,681.17. Plumbing, heating and electric-wiring contracts will bring the total for the com-Other tenders were put in by G. A. Fuller Co., Montreal, and W. Cowlin Co., Toronto.

PERSONAL

Captain James Warwick, a well known marine man, passed away at Courtright, Ont., on March 11. Deceased was 72 years of age.

Fraser S. Keith, B.Sc., for the past eighteen months editor of "Construction" has been appointed secretary of the Canadian Society of Civil Engineers, Montreal, in succession to Professor C. H. McLeod, resigned.

Corp. Robert John Dawson, of the P.P.C.L.I., has been killed in action. Corp. Dawson went overseas with the 3rd University Company. Prior to enlisting he was engaged as a salesman for the Canadian Fairbanks-Morse Co., Front Street, Toronto.

CONTRACTS

Ottawa, Ont.,—The City Council has awarded a contract for valves to the Drummond McCall Co., Montreal.

Lindsay, Ont.—A contract has been awarded by the Town Council to the Norwood Eng. Co., Sherbrooke, Que., for filters and accessories at a contract price of $21,500.

Pembroke, Ont.,—The Pembroke Electric Light Co. has awarded the following contracts, for an 1800h. p. horizontal turbine. The Boving Hydraulic and Engineering Co., Lindsay Ont; generator, tranformer and switchboard, the Canadian Westinghouse Co., of Hamilton.

INCORPORATIONS

Santoline, Ltd., has been incorporated at Toronto with a capital of $40,000 to manufacture soap, greases and disinfectants, etc., at Toronto. Provincial directors are D'Arcy G. Grierson, James Bell and Richard Davis, all of Toronto.

Dodge Brothers Motor Co. has been incorporated at Ottawa with a capital of $100,000 to manufacture and deal in motor cars and trucks, etc., at Windsor, Ont. The incorporators are John F. Dodge, Horace E. Dodge, and Fred Y. Haynes, all of Detroit, Mich.

The Signal Motor Truck Co., of Canada, Ltd., has been incorporated at Toronto with a capital of $50,000 to manufacture motor trucks and automobiles at Toronto. The provisional directors are John S. McLaughlin, Fred E. Earl and James McFadden, all of Toronto.

Atlantic Pulpwoods Ltd., have been incorporated at Quebec, with a capital of $500,000 to build and operate paper and pulp mills. The head office is at Montreal, and the incorporators are Charles N. Blackeley, Charles M. Cotton and Frederick T. Enright, all of Montreal.

Angus Power Co. has been incorporated at Ottawa with capital of $500,000 to carry on the business of electricians and mechanical engineers, also to construct and operate power plants. Head office is at Montreal, and the incorporators are: Errol Languedos, Jean P. Charbonneau and Ralph E. Allan, all of Montreal.

WOODWORKING

Collingwood, Ont—Fire on March 6, destroyed the planing mill of the Wilson Mfg., Co., entailing a loss of over $100,000, largely covered by insurance.

Danville, Que.,—The factory and warehouse of the Danville Chair Co., was destroyed by fire recently, the machinery and contents being a complete loss. The total loss is estimatel at $50,000.

RAILWAYS—BRIDGES

Hamilton, Ont.—The Board of Control has decided to engage W. F. Tye, railway engineer, Montreal, providing satisfactory terms can be arranged, to report on the most feasible common entrance for all railways desiring to enter Hamilton from the west.

Haileybury, Ont.—The car barns of Nipissing Central Railway, North Cobalt, partly destroyed by fire on March 4. Five cars were completely demolished, but the transformers and three cars were saved. The damage to the building is estimated at $40,000, the five cars at $60,000 and electrical equipment $30,000 making a total loss of $130,000.

MARINE

Victoria, B. C.,—Three of the 260foot auxiliary schooners building at Victoria and North Vancouver in the shipyards of the Wallace cncern and the Cameron-Genoa Mills Shipbuilders Ltd., will be in the water by March 19. The third vessel Laurel Whalen will be launched on that date.

Vancouver, B.C.—A new order for three big steel steamers has been placed by the British Government with John Coughlan & Sons, of this city. They will be 8,800-ton ships of the same size and design as those being constructed under the order for the three boats by a Norwegian syndicate with the same firm.

St. John N. B.—At the monthly meeting of the Board of Trade held on March 6, it was decided that both the Federal and Provincial Governments be memoralized by the Board of Trade in the matter of shipbuilding, and that some kind of bonus and a definite scheme be laid down for the encouragement of this industry.

Victoria, B. C.,—In addition to the two car barges which are about to be built for the C. P. R. the contracts for which are expected to be let in the course of the next few days, Capt. J. W. Troup, manager of the B. C. Coast service, announced that the company intended to call for immediate tenders for the construction of a 1200-ton capacity freight barge which will be used for general freight purposes.

Navigation Will Open Late.—Reports ports are unanimous in the opinion that navigation this year will be at least two weeks late in starting. Heavy ice is reported everywhere, with considerably more of it than a year ago. In Buffalo harbor thirty inches of ice is reported, and vessels with storage grain are experiencing considerably difficulty in working their way to elevators. In Lake Erie the ice field extends beyond view and is from 15 to 20 inches in thicknes.

TRADE GOSSIP

B. C. Sulphuric Acid Plant.—Trail smelter's sulphuric acid plant has been operating steadily since last July and is turning out its regular quota of acid which makes it possible to operate the several refineries in connection with the works—lead, copper, zinc and slimes. A. L. McCallum is the superintendent.

U.S. Steel Orders.—The unfilled orders of the U.S. Steel Corporation on February 28 were 11,576,697 tons, breaking all previous records. The figures showed an increase of 102,643 tons over the report for January 31st, last. The previous high record was that for December 31st, 1916, when the unfilled orders stood at 11,547,286 tons.

Cnnard Orders Placed in Seattle.—The Ames Shipbuilding & Drydock Co., of Seattle, have signed contracts to build

nine large steel steamships at a cost of more than $11,000,000. Seven ships of 9,000 tons each for the Cunard Line are among the boats. Keels for the first three Cunarders will be laid during the present month.

Canada's Fire Loss Heavy.—Canada's fire loss during February, was $2,009,953, compared with $1,918,660 in January, and$3,275,600 in February, 1916. The city of Quebec is unenviably prominent reporting four important fires during the month with loss totalling $400,000. Individual fires entailing a loss of $100,000 or more also occurred in Hamilton and Winnipeg.

The Mechanical Engineering Co., Montreal, are moving their business to Three Rivers, Que. The new factory will be of brick construction with concrete floors and columns. The plant will be modern in every way and cost approximately $100,000. A large machine shop will be the most important feature of the plant, where new machinery will be installed. Mr. Barrie is the superintendent.

Further Trade Restrictions.—According to a cable received from the British Board of Trade at the Montreal office of H. M. Trade Commissioner for Canada, further restrictions of exports from Great Britain have been made.—These include copper manufactures, telegraphers and telephones, various implements for munitions foodstuffs starch, refined tallow, albumen, casein, and dextrine.

Demand for Ships on Atlantic.—So great has been the demand for vessels on the Atlantic seaboard during the last year that 71 Great Lakes steamers, with a total tonnage of 683,770 tons, have been transferred to deep-water service. These vessels are now all operating out of Atlantic Coast ports, according to advices from the East. In Great Lakes shipyards there are at present 59 vessels building, which will be completed during 1917. It is believed that the majority of these craft will be sent to the Atlantic for service also.

West Indies Conference.—At Port of Spain, B.W.I., the Associated Chambers of Commerce of the British West Indies discussed England's prohibition of cocoa and rum as imports, and a resolution was passed urging that the prospective customs conference include commercial representatives, and that it also discuss the possibilities of freer trade intercolonially. Other resolutions adopted favored the restriction of business activities of enemy subjects, compulsory registration for aliens, facilitation of exchange of laborers between colonies, development of oil resource metric system, and the purchase of Government supplies by Government agents.

Canadian Mining Institute.—The 19th annual meeting of the Canadian Mining Institute was opened at the Ritz-Carlton Hotel, Montreal, on March 7. The presidential address was delivered by Arthur A. Cole, who reviewed the work of the Institute and stated that abnormally high prices of metals has increased profits and stimulated output so that the year 1916 established a new high level record for production. E. P. Mathewson read an interesting paper on "Industrial Preparedness," while Dr. Frank D. Adams, of McGill University, explained the work of the advisory council for scientific and industrial research. Several other papers were read dealing with minerals and their uses.

Record Prices for Steel.—Steel bars, plates and shapes have never sold higher in the history of the trade than the prices reported from Pittsburg as put into effect recently by the Carnegie Steel Co. Plates were advanced $15 a ton. Bars and shapes were put up $7 a ton, making the quotations 3.35 cents a pound for bars and 3.75 cents for shapes. Last Monday wire products were lifted $4 a ton, the entire development supplying the most spectacular week, so far as prices are concerned, since the current boom got under way. The enomous demand for ship plates from the yards at home and abroad has been the dominant factor in the plate price increase, and structural shapes have also been affected by the expanding shipbuilding industry.

C.P.R. Exhibit of Hydro-Electrics.—To emphasize the economic importance of electric products, and to show their relation to other industries is the object of the C.P.R. Hydro-Electric Exhibit opened on last Monday in the Shaughnessy building, McGill street, Montreal. The exhibit is under the direction of Arthur D. Little, as a part of the Natural Resources Survey. The exhibit has been arranged to interest the layman as well as the specialits, and although it is essentially technical in character, processes are explained so clearly in the accompanying placords, that he who runs may read. An instance of this is the series showing the evolution of the modern incandescent electric lamp. An interesting item shown will be a shell piercer punch with an actual record of having pierced 24,000, 4.5 inch shells.

Will Build Cunarders at Portland.—Several steel freighters of 9,000 tons deadweight capacity will be built for the Cunard Steamship line at Portland, Ore. The contracts here will be divided between the Northwest Steel Co. and the Columbia River Shipbuilding Corporation, with probabilities that increased facilities will be provided. At present the Northwest Steel Co. is the holder of eight contracts for ships of 8,800 tons deadweight, and the Columbia River Shipbuilding Corporation has six of the same size, with at least two Cunarders. Three are well under way at the Northwest plant, and two of those building have been sold to the Cunard line, while at least two others that will be ready for delivery in the fall have been under negotiation, the four having originally been contracted by Lauritz Kloster, of Norway.

Big Increase in Revenue.—Revenues are indicated in the February financial statement issued at Ottawa on March 8. The fiscal year ends this month and a fifty million increase is in prospect. For the eleven months the revenue aggregated $205,417,039, as against $154,,348,809 for the corresponding period. February revenue alone was $17,513,473, an increase of two and three-quarter millions. The total revenue for the fiscal year is estimated at $225,000,000. Customs and miscellaneous revenue, including the business tax, were the principal sources of increases. Expenditures on current account in the eleven months were $113,161,357, and on capital $259,597,008. War outlays in eleven months were $217,590,670. This is almost double the war expenditure for 1916. It is now about a million a day. The total net debt is now $765,061,893, which is an increase of nineteen millions in the past month.

Trade With Russia.—Jonas Leid managing director of the Siberian Steamship, Manufacturing and Trading Co., stated recently that there was no reason why Canadian goods could not find a ready market in Siberia, but to capture this trade, he said that it was not sufficient to send out catalogues and invite orders, but agents had to be sent direct to the country to get in touch with the people. Their imports were manufactured goods and their exports were mostly agricultural produce, and he saw no reason why Canada should not be importing Siberian butter in the near future. The railways were blocked on account of the war, and the sea route via the Kara Sea seemed to be the only relief. The vessel which the company sent out last year was sunk by a submarine, but this year they intend-ed starting two specially built steamers, with a tonnage of 6,100 tons, from same American port, and take the passage north of Iceland and north of Norway, then through the Kara Sea to their destination. This route, Mr. Leid explained, was beyond the reach of submarines and was a safe one, as evidenced by the low rate of war insurance on ships taking this route. If they saw that it was possible to take a cargo from Canada they would be prepared to do so, for Siberia was ready to take almost anything in the manufactured.

BOOK REVIEWS

Wire and Sheet Gauge Tables and Metal Calculator, by Thomas Stobbs; 95 pages; 5 x 7½ in. Published by E. & F. N. Spon, Ltd., London, England. Price (3s. 10d.) 95 cents net. This is a new book containing English, metric and foreign wire and sheet gauge tables, with net and gross divisors for finding net and working weights, allowances for mill scrap, etc., with worked examples, weights of all sections of precious and common metals. The book also contains English and metric weight and measure tables with equivalents. The book forms a handy metal calculator and ready reckoner for office and shop use in sheet plate and rod mills, and forges. It is a very useful hand book for merchants and manufacturers, and those connected with the wire, sheet steel and other metal industries. The examples of calculaltions which precede the tables are worked out in both the English and metric systems, and form a useful feature of the book.

CATALOGUES

Tap Extractors. — The Walton Company, Hartford, Conn., are distributing two bulletins describing and illustrating a useful device for removing broken taps. The method of using the tool is described and price list included.

The Homestead Valve Mfg. Co., Homestead, Pa., are distributing a bulletin bearing the title "Safety First, then Efficiency, then Economy," having reference to the Homestead line of valves. The "Hovalco" blow-off valves and "Homestead" quarter-turn valves are also illustrated and described.

The American Pulley Co., Philadelphia, Pa., have issued a booklet entitled "Building 25," descriptive of a new building recently opened at the plant for the convenience of workmen and for safeguarding their health. The booklet contains descriptive matter, and also a series of photographic views showing the principal features of the building, embodying the latest ideas applied to the preservation of health in factories.

Oxy-Acetylene Welding. — The Davis-Bornanville Co. are distributing a bulletin dealing with oxy-acetylene welding and cutting. The bulletin describes the development of the oxy-acetylene process and the progress made by the Davis-Bornanville Co. in connection with this development. The apparatus and its wide range of service are fully described while illustrations show the various types of outfit and torches. Copies of the bulletin may be obtained from the Canadian representatives, the Carter Welding Co., Toronto.

Pipe Machines.—The Williams Tool Co., Erie, Pa., have issued a catalogue illustrating and describing an interesting line of pipe threading and cutting off machines covering a wide range of sizes. A general description for each type covers the principal features and gives the leading dimensions. An interesting feature is a list of repair parts, numbered and illustrated for each type of pipe machine. Each type of machine is shown arranged for belt or motor drive. The concluding pages show special designs of pipe machines direct connected to gasoline and steam engines.

Abrasive Grinding Wheels is the title of an attractive new catalogue No. 6, issued by Abrasive Company, Philadelphia, Pa. The catalogue contains an extensive list of special shaped abrasive grinding wheels for miscellaneous grinding machines. The wheels are classified and illustrated with principal dimensions and price given for each size. Straight, cup and cylinder wheels are also listed, accompanied by rules for calculating list prices. A chapter is devoted to the use and care of wheels, followed by a set of rules for calculating speeds. The principal points involved in the process of manufacture of these wheels, which are made of boro-carbone and electrolon, are briefly described. A table for selection of grain and grade for various classes of work is a useful feature of the catalogue and one of considerable help when ordering. The catalogue contains telegraph and cable codes and general index. Copies may be obtained from the Canadian distributors, the Canadian B. K. Morton Co., Toronto and Montreal.

PULP AND PAPER INDUSTRIES IN BRITISH COLUMBIA

IF plans in process of being perfected by several companies are successfully carried through, the pulp and paper-making industry in British Columbia will be given a great impetus, and will bring into revenue-producing position some large tracts of timber lands which have been held for some years as pulp concessions. Three large pulp and paper plants have been erected in British Columbia in the past twelve years, but two only have been in operation. One of these, that of the Powell River Co., some hundred miles up the coast of the mainland from Vancouver, has been manufacturing news print and other paper for some years, and the other, that of the B. C. Sulphite Fibre Co., at Mill Creek, Howe Sound, has been making sulphite pulp at its plant for some time since its reorganization.

Great things were hoped for and predicted of the pulp and paper industry some twelve or fourteen years ago, when the then Provincial Government inaugurated a policy of pulp concessions to induce capital to build paper mills in the province. It costs a good deal of money merely to secure and cruise a pulp timber limit. In the time that has intervened since the policy was first established, progress has been somewhat slow in developing the industry, which is capable of becoming such a factor in commerce and production from the timber resources of British Columbia.

To-day, through altered trade conditions brought about by the war, and accentuated by its continuance, more attention than ever before is being given to development. There will be activity on all the pulp concessions which have been granted, and which have been held ever since the days when the plan was devised. Two large plants which have lain idle almost since their construction are being placed in order for active operations. On the fourth concession, that at Quatsino Sound, on the north end of Vancouver Island, where no mill has yet been erected, the interests controlling it are said to be making plans for early construction.

Trade Inquiries

THE Department of Trade and Commerce, Ottawa, has received the following enquiries:—

558. Agency.—A Durban firm specializing in machinery and mechanical appliances is prepared to take up Canadian agencies on lathes, drilling machines machine tools.

569. Boilers.—Canadian manufacturers of hot-water boilers having a heating capacity of not less than 800 feet are asked to communicate with a Newfoundland inquirer.

AMERICAN MACHINERY EXPORTS

THE value of the exports of machinery from the United States in the seven months ended January 31, this year, was $92,518,708, as compared with $44,993,573 in the corresponding period of 1914-15. The largest exports in the seven months ended January 31, this year, were metal-working machinery, which represented a value of $25,196,917. The value of certain other exports was: —Gasoline engines, $4,423,507; steam-engines, $11,151,462; parts of engines, $3,714,109; milling machinery, $1,584,442; paper-mill machinery, $3,766,695; sewing machines, $3,092,705; sugar machinery, $4,902,099; and typewriting machines, $4,654,166. The value of the machinery exported from the United States last year was $134,128,862, and that of machine tools, $41,037,779. The American International Corporation has bought up the Allied Machinery Company of America, and proposes to extend the business of that undertaking, which aims at assisting American manufacturers of machine tools to place their products in foreign countries. The company has shown rooms in Paris, Petrograd, Zurich, and Turin.

Empire Resources Development.—A great private organization, aiming "to promote the development of the Empire resources in order to assist in the payment of the war debt," has been launched under a committee styled the Empire Resources Development Committee. The chairman of the committee is Sir Leander Starr Jameson, president of the British South African Co., and its membership includes Earl Grey, Lords Selborne, Desborough, Dunraven, Islington and Plymouth; Alfred Bigland, L. W. Evans and A. H. Paget, members of the House of Commons, and Rudyard Kipling. The purposes of the committee are outlined as "conservation for the benefit of the Empire, of such natural resources as are or may come under the ownership of control of the Imperial, Dominion and Indian Governments; the development of selected resources of the Empire under such conditions as will give the State an adequate share; and conserving and developing the resources of the Empire so the Imperial effort may concentrate on assets ripe for development for the common good of the Empire."

You tell me that there are many unpleasant things troubling you in the place in which you work. If you can answer without betraying a secret,—would you mind telling me if you ever knew of velvet being used successfully as a substitute for sandpaper? The unpleasant, the hard, the trying, the temper-testing things are the sandpapery aids that smooth you off—that train you—that fit you to shoulder bigger responsibilities and to resist more trying troubles later. So be very thankful for the sandpaper.

FOR SALE

FOR SALE—ENGINE LATHE 30" SWING, 8 ft. bed. Putnam make, good strong tool, cheap Box 269, Canadian Machinery. (cSm)

FOR SALE — LOT OF WOODWORKING machinery — shafting, pulleys, hangers, belting, etc. Cheap. Box 270, Canadian Machinery. (cSm)

FOR SALE—PIG LEAD AND LEAD IN 10-lb. bars for immediate shipment. We can sell this at considerably below market quotation. Geo. E. Jobborn, 56 Guise Street, Hamilton. c9m

GAP LATHE, 28 x 42 x 16 FT. BED, FOR sale, cheap; also emery wheel stand, power hack saw. Guarantee Motor Co., Hamilton, Ont. (tf)

FOR SALE, AT A REASONABLE PRICE —three 3¼" and two 2¼" style C geometric die heads, with 1¼" shank. H. Mueller Mfg. Co., Ltd., Sarnia, Ont. c9m

FOR SALE—ONE 450 H.P. THOMPSON & Williams condensing engine. Will sell cheap. Engine is in first-class repair and will give every satisfaction. Apply J. A. Marven, Limited, Moncton, N.B. tcfm

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make, used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

TRUCKS—A NUMBER OF SECOND-HAND trucks, manufactured by the Watson Manufacturing Company, Limited, Ayr, and Wm. and J. G. Greey, Toronto. Approximate size 26" x 48". Price $7.50 each f.o.b. Toronto. In good shape. The A. B. Ormsby Company, Limited, Toronto. c11m

FOR SALE—88 H.P. CROSSLEY GAS ENgine. Will develop 115 H.P. on natural gas; in perfect condition. Used only 18 months. Speed 200 R.P.M. This is suction gas plant with producers, compressor and tanks, but is ideal for natural gas. Will sell cheap. P. L. Robertson Co., Milton, Ont. c11m

1 ONLY — 10" WESTINGHOUSE LOCOMOtive air compressor, first-class condition, all complete, ready for installation. 1 only, 6 x 6 Imperial type Canadian Ingersoll-Rand Company air compressor, in good condition, complete, ready for installation. H. Mueller Mfg. Co., Ltd., Sarnia, Ont. cSm

ONE LATHE 16" x 4½' back geared. Built by P. P. Silk Machine & Tool Co., Cincinnati, Ohio. One lathe 18" x 3', back geared. Built by the Bradford Mill Co., Cincinnati, Ohio. Four Murchey Collapsible Dies. Capacity 1½" to 2¼". Box 272, Canadian Machinery. ctmf

FOR SALE—2 KENNEDY CUTTING-OFF machines, for cutting off both ends of 4.5 H.E. forgings; in good condition; price $750 each. 1 18-pdr. Holden-Morgan thread miller for threading base end of high explosive shells; price $300. 1 18-pdr. H.E. marking machine; price $50. Apply to Alton Foundry Co., Ltd., Alton, Ontario. c13m

3—20 H.P., 60 CYCLE, 440 VOLT, 3 PHASE, 900 R.P.M. induction motors with starting compensators and adjustable sliding bases; Canadian General Electric Company's latest type, practically new, $350.00. 2—15 H.P., same as above, $315.00; 1—35 H.P., same as above, $440.00; 2—5 H.P., 1200 R.P.M., complete, with pulley 5½ diameter, 4½ face, otherwise the same as above motors, $95.00; 2—2 H.P. pulley, 4½ diameter, 3½ face, $80; 1—1 H.P. pulley, 4 in. diameter, 2½ face, $65. Prices f.o.b. Sarnia. Perfection Stove Co., Ltd., Sarnia, Ont. c11m

WANTED

WANTED — MOTORS 10 TO 50 HORSEpower, 25 cycle, 550 volts, alternating current. Quote price and delivery. Canadian Fairbanks-Morse Co., 1379 Bloor Street, Toronto. c11m

SPECIAL MACHINERY

MANUFACTURERS — WE CAN UNDERtake work to any specification—munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

SITUATIONS WANTED

MAN ABOUT 30, WITH ENGINEERING and commercial training, experienced in mine and smelter requirements, including structural and cast steel work. A man with office experience and capable of soliciting business preferable. Box 283, Canadian Machinery. c13m

MECHANICAL ENGINEER WITH LONG experience designing and estimating on machine tools, special shell machinery, tools, jigs and fixtures, desires responsible position with well established company. Best of references given from well-known companies. Box 284, Canadian Machinery. c12m

SUPERINTENDENT WITH NINETEEN years' mechanical experience in manufacturing and repairing of machinery and structural steel, both shop and erection, desires change of position. Experienced in machining 18-Pr. and 4.5" high explosive shells. Aggressive character, good organizer, best of references. Box 282, Canadian Machinery. c12m

MACHINE SHOP FOREMAN, EXPERT all round machinist with technical training desires to connect with aggressive engineering firm. Twenty years' practical shop experience—four years in stationary and marine engine works, 4 years in steel plant, 2 years' tool room experience, 10 years in locomotive shop. Box 279 Canadian Machinery. c11m

SUPERINTENDENT OR WORKS MANAGER of large metal working plant desires change. Broad gauge man of modern methods and a producer of results. Over 20 years' experience at handling large forces of workmen in manufacture of high quality and interchangeable goods of brass, iron and steel, special tools, dies, machinery, etc. Includes brass works, machine shop, punching and stamping and fine brass work, taking entire control of plant. English-American descent. Box 280, Canadian Machinery. c11m

SITUATIONS VACANT

BRASS MACHINE FOREMAN WANTED—man capable of handling small brass shop on munitions. None but a hustler need apply. Box 277, Canadian Machinery. c11m

DIE MAKERS—SERVICES OF TWO FIRST-class die makers to work on small dies for parts of electrical wiring devices. Apply Toronto Electrical Supply Work, King street Subway. c10m

WANTED—MACHINERY SALESMAN FOR Michigan territory. Must have experience with both new and second-hand machinery, and capable of getting results. In applying, state experience and salary expected. Box 276, Canadian Machinery. c11m

A GOOD SALES ENGINEER TO OPEN office to sell Moline Heat in Canadian territory. Must be a good salesman, having had a general heating and ventilating experience. Must give good references. We have a fine proposition for the right man. Address, Moline Heat, Moline, Ill. ctmf

FOREMAN TOOL MAKER WANTED ON electrical sockets and appliance work. Preference will be given to man who has had experience with automatic feeding of punch presses for blanking and forming operations. It is essentially necessary that the applicant has had experience in brass drawing dies. Only first-class men need apply. State experience and wages. Apply Box 278, Canadian Machinery. c9m

INDEX TO ADVERTISERS

8 Inch H. E. Shell Production in a Machine Tool Plant

Staff Article

The plant here described has earned the distinction of successfully undertaking the production of 18-pdr. shrapnel, 18-pdr. and 8-in. high explosive shells; the two former of which have already been featured in these columns. It seems, therefore, appropriate that the departmental layout and equipment for machining big shell should also be given a place.

THE production of 8 in. howitzer shells on a quantity basis has been in progress in Canadian factories for nearly a year, and the number of plants now producing possess numerous individual features of interest to machinists. The variation of method encountered in the making of 8 in. shells is greater than that met with in shrapnel, in proportion to the number of firms engaged; not only that, but the differences in 8 in. shell work are more basic in their origin and greater in their influence on the work as a whole, than the numerous variations of procedure which were evolved in the manufacture of shrapnel.

Previous articles on 8 in. shell work which have appeared in these columns have dealt with plants which handled the problem in one of two methods, i.e., a judicious combination of special and standard machine tools with such variations in tool equipment and handling methods as were due to the individual tool designers, or, a full equipment of specially built machine tools, each of which forms a unit of an inflexible system, the adoption of which allows the free use of unskilled labor with a maximum output, subject, however, to more frequent inspection, etc. The plant described herewith belongs to the first class of plant mentioned, but possesses a unique individuality in regard to one or two features which will be referred to in due course. The sequence of operations, degree of accuracy, and types of machines employed are, however, characteristic of a plant which has been accustomed to heavy machine tool work of the highest class and which consequently approached the work from the tool-builders' viewpoint, rather than that of emergency production with extemporized equipment.

Uniformity of Machine Groups

Due to a fortunate combination of circumstances, it was possible to secure the machines in groups, thus rendering possible the duplication of tool equipment for all the machines engaged on a particular operation; it further prevented any drop in output when an operator for any reason had to change to another machine. The existence of a three-bay shop of very modern design enabled the installation of the machines to be accomplished in a most efficient manner, unhampered by lack of space, transmission equipment or handling facilities.

The plan view of the shop, Fig. 1, shows the path of the work which is purely progressive. Starting from the point where the forgings are discharged from the freight car, the work passes up No. 1 bay and half-way down No. 2 bay in parallel streams, thence down one side of No. 2 bay and up the other, crossing into No. 3 bay half-way up, thence up one side and down the other to the inspection, marking, and shipping which occupy the full width of the remainder of No. 3 bay. Each bay is

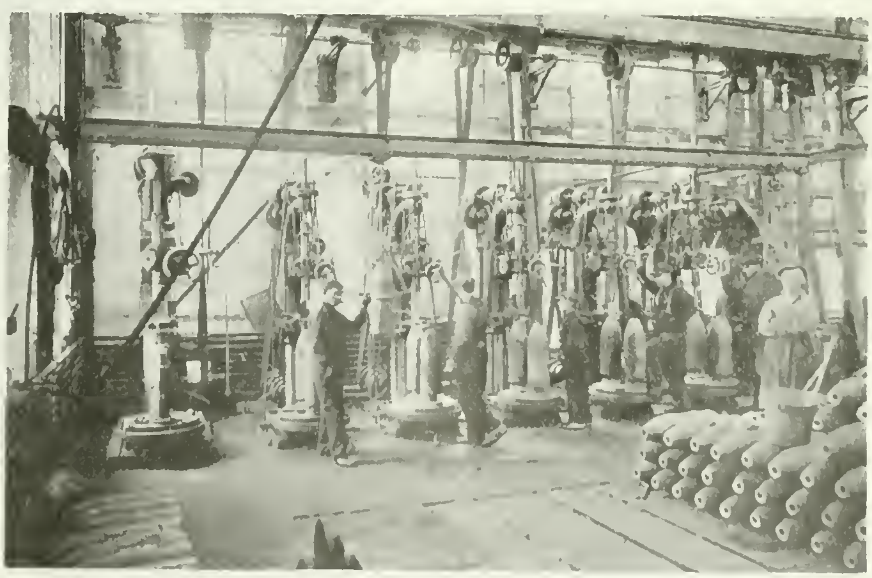

FIG. 3. BATTERY OF DRILL PRESSES WITH REVOLVING TABLE EQUIPMENT, DRILLING AND FACING HOLE IN NOSE.

served by a 5-ton Niles crane, which was part of the original equipment, and was of great service in laying out the present installation.

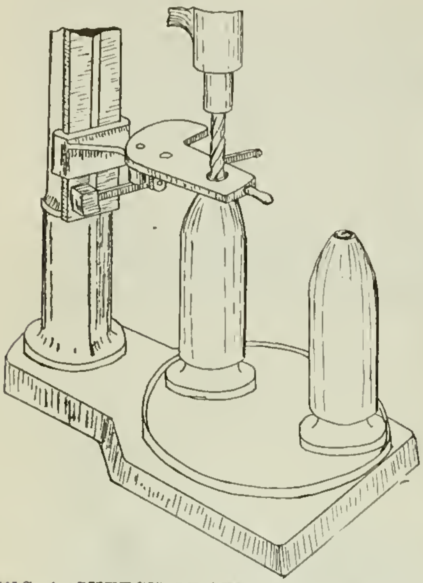

FIG. 4. SKETCH OF SWIVELING JIG USED FOR STARTING DRILL IN NOSE.

The conveying of the shells is entirely along raised tracks on which they roll; each machine being equipped with half-ton quick-acting chain blocks of the Herbert Morris type, slinging belts, hooks and automatic clamps being used for gripping the shell as required.

Forgings Tested on Receipt

Immediately on receipt, the forgings are tested for concentricity on an indicating fixture, Fig. 2, with a pointer and scale as shown. Should there be sufficient thicknesss in the walls, it is possible to divide the eccentricity between the boring and the turning, thus necessitating special locating of the hole in the nose. All normal shells, however, are immediately drilled and faced in a battery of six Bertram vertical drilling machines shown in Fig. 3. Each machine is an independent unit with revolving work table having two centering arbors for supporting the

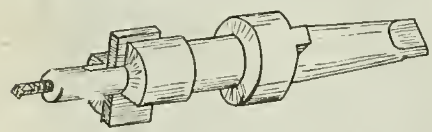

FIG. 5. FACING CUTTER AND BAR FOR FACING NOSE.

forgings. A trolley track extends along the row, immediately above the idle arbors and the forging is hoisted up to the proper height by a pneumatic hoist at the extreme left where the chain block is attached and the forging transferred to the particular spindle desired.

No marking-off is resorted to. A swivelling jig plate is mounted on the drill column, Fig. 4, both forging being drilled first and then faced by a double cutter bar, Fig. 5, of simple and efficient design. It is provided with driving keys on a collar which engage in a slot in the drill spindle, as the heavy duty was too severe for any ordinary drill tang with flat ends.

The faced nose is now used to locate forging in the chucks of three Root & Van Dervoort cutting-off machines. Two cutting tools are employed, and are offset with respect to each other so that ample clearance is obtained to prevent undue choking and heating of the tools as the depth of cut increases. As indicated in Fig. 1, these machines are at the beginning of the tracks, two machines being on one side to supply the greater number of rough-turning lathes adjacent thereto.

Roughing and Boring

Thirteen 24-in. Bridgeford lathes are engaged rough turning. These lathes are equipped with two carriages, for parallel and radial travel, link control of the usual type imparting the curve to the nose. During this operation, the shell is supported by a pipe centre in the nose, and is driven by a three-jaw automatic expanding driver of the eccentric groove type. The turned shell is then lifted by a flat belt sling and chain block and deposited in the open-sided chuck of one of the boring lathes, Fig. 6. It is clamped in position by two hinged straps. The machines used for this work are built by Niles-Bement-Pond, and are of their standard shell boring design with individual motor drive and square boring bar fed by rack and pinion in tailstock and supported by sliding brace gibbed to ways of bed.

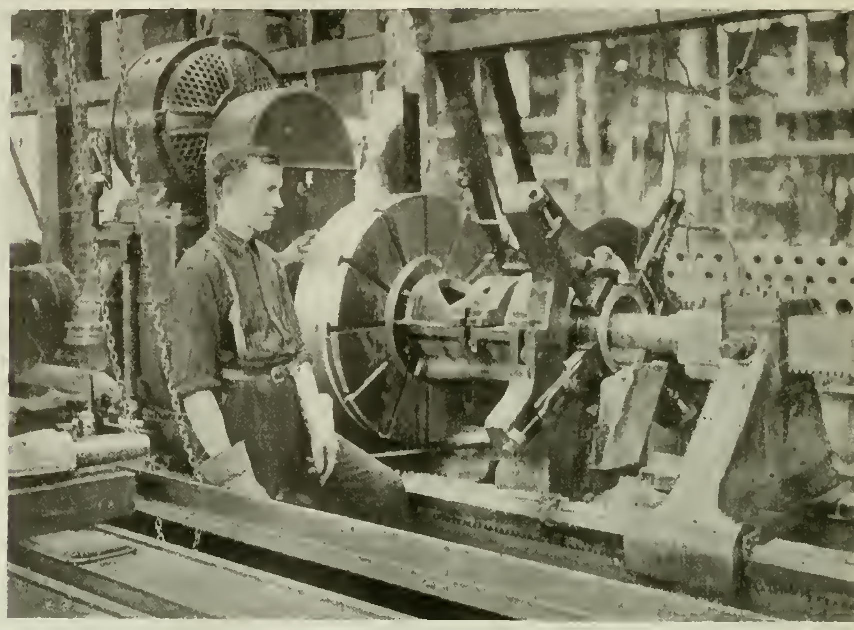

FIG. 6. MACHINING INTERIOR COMPLETE IN SPECIAL BORING LATHE.

The regular run of forgings are finished with two cutter heads of the acorn type. The first or rougher is three-bladed with notched edges, and the second is double-bladed with smooth edges. Occasionally a forging with bore rather much off centre necessitates the use of a preliminary rougher which has three blades with notches of a special

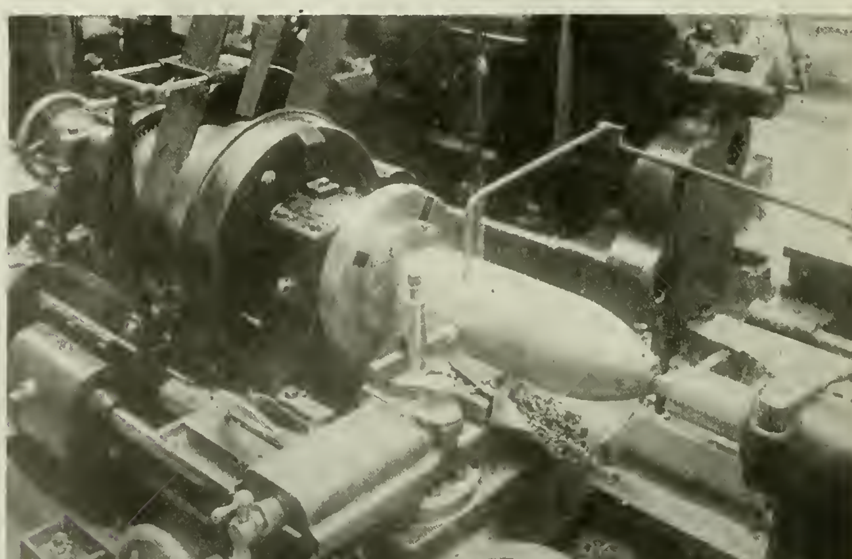

FIG. 7. FINISH TURNING SHELL BODY TO GAUGE.

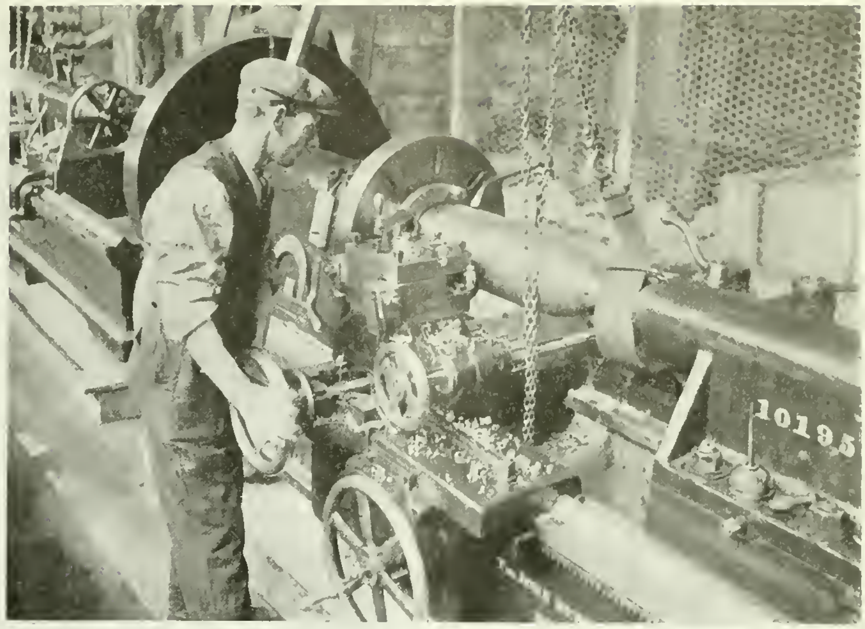

FIG. 10a. GROOVING AND WAVING FOR COPPER BAND.

design which enable the uneven cut to be handled satisfactorily. The trued bore is then completed with the two regular cutters. All of these cutters are made with taper shanks, and are ground to form in a special grinding machine which holds them by the shank. All curves are obtained by swivelling the

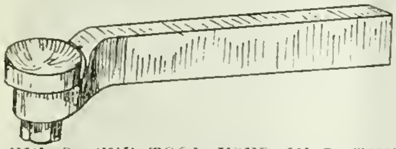

FIG. 8. CUP TOOL USED IN LATHE SHOWN IN FIG. 7.

chuck around points, stops and adjustments enabling the desired outline of the blades to be quickly and accurately attained.

Finish Turning

The shells have now reached the end of No. 1 bay and are transferred by a roller conveyor track to No. 2 bay where finish turning is done. In this, and in the previous operation of boring, no limit is allowed on the finished diameters. The shell is carried on an expanding mandril which extends through the nose and is supported on the tailstock centre. The body of the mandril also acts as a positioning stop inside the nose so that the thickness of the nose is

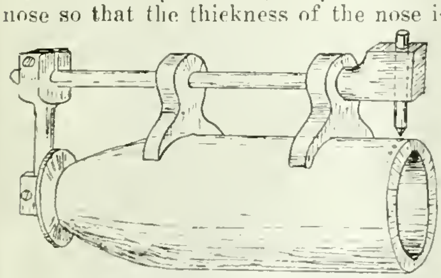

FIG. 9. SKETCH OF LENGTH GAUGE WITH PRICK PUNCH.

duplicated in every shell; up till now the base end has been left as it came from the cutting-off machine, that is, with a small allowance for trimming to size.

Great care is taken to see that the mandril dogs are kept true, grinding being done at regular intervals to insure concentricity between the finished bore and the exterior which is now being

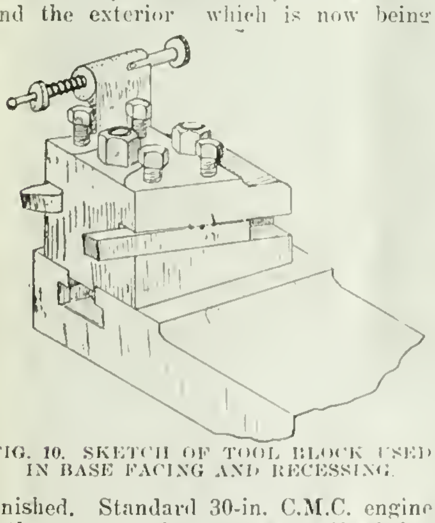

FIG. 10. SKETCH OF TOOL BLOCK USED IN BASE FACING AND RECESSING.

finished. Standard 30-in. C.M.C. engine lathes are employed, the profile being obtained through template bar mounted at back of bed. As the template and the mandril are fixed in relation to each other, uniformity in thickness of nose wall is assured.

The cutting tool is of the circular cup type which gives maximum length of cutting edge with one sharpening (see Fig. 8), and gives a clean, smooth surface on the work. These lathes are all belted up on the middle step of the cone and fitted with two-speed countershaft which enables the operator to speed up on the nose as the diameter decreases. Speeds provided are 93 and 157 ft. per min. This high rate of cutting is largely due to the use of shell forgings made from cast billets, the texture being very uniform and the cutting qualities much superior to forgings made from rolled billets.

Finishing Nose

All of the finish machining on the nose with the exception of threading, is done in two Davis turret lathes with four-tool equipment consisting of flat bevel cutter for mouth of hole, single point boring cutter, recessing tool, and two-diameter reamer. The base of the shell is carried on an expanding arbor operated by handwheel while the body is supported by a steady rest at the end of the parallel portion. The peculiar properties of the cast forgings gave some difficulty in obtaining a suitable material from which to make to jaws of the steady rest. Hardened steel had too much tendency to heat and tear up the surface, brass was much better but did not last, while cast iron was a moderate improvement on brass. Chilled faces on the end of the cast iron jaws proved very satisfactory, giving a long life, with almost entire absence of heating, and no detrimental effect on the surface of the shell.

Weighing Dispensed With

With the exception of the base end, all of the shell is now machined to exact sizes with no limits. It follows,

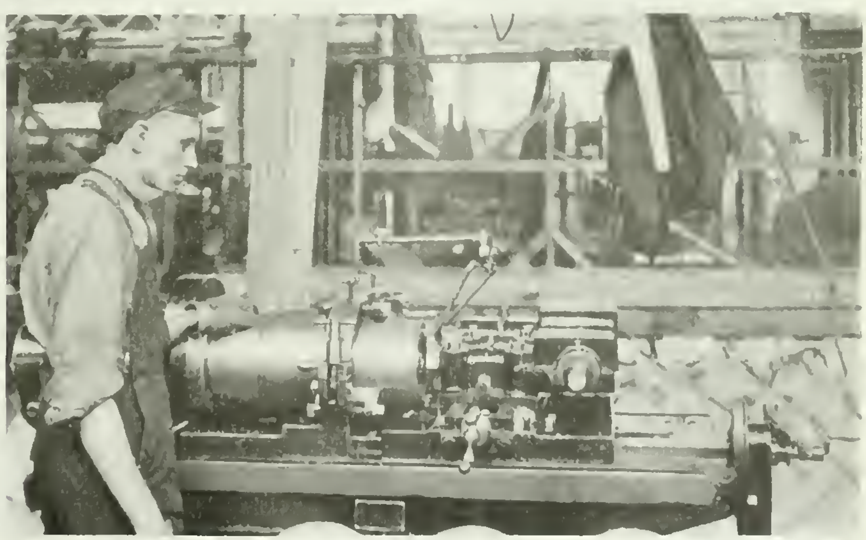

FIG. 11. MILLING BASE THREADS IN DUPLEX MACHINE.

therefore, that if the length be made exactly to a uniform dimension, the weights of the various shells will be exactly the same, except for any slight variation in density of the metal which is entirely negligible in actual work. The shells, therefore, are now marked for overall length by means of a prick-punch gauge (Fig. 9), and are passed over to the base finishing operation which employs three Bridgeford 26-in. engine lathes with draw-in collet chucks and outer steady rest.

The tool carriage of these lathes is fitted with a special tool block having two tools and an indicating gauge. A sketch of this is shown in Fig. 10, which shows the tool block bolted in place of the ordinary tool post. Tool A is beveled off to a round point, and is used for facing off the end of the shell to the punch marks. Tool B is then moved across to position, and fed into the end of shell, forming recess for adapter flange. The spring indicator C, is mounted so as to bear against the finished end of shell and show when tool B has cut to the required depth. Tool A is now used for chamfering the ragged edges on inside and outside of shell, which now proceeds to the grooving machines.

FIG. 13. COPPER BANDING EQUIPMENT.

Grooving and Waving

Three special Bertram grooving lathes are used, with positive eccentric drive to waving tool. A four-sided revolving tool post enables the grooving, waving and undercutting to be performed in rapid succession. The reciprocating drive for waving tool is by a back shaft from the end of headstock, a clutch operating lever being located within easy reach of the operator on the front of the headstock.

The threads in nose and base are now milled in Bertram milling machines. The nose is done first, the shell being gripped in a draw-in collet chuck and supported in steady rest. In actual operation the spindle is allowed to revolve continuously, while the shells are being inserted and removed, the speed being about one revolution in 20 seconds. The carriage is fed along by lead screw to coincide with pitch of cutter, a clutch on the lead screw shaft allowing the cutter to be moved to position, and split nut engaged, after which the clutch is thrown in and the cutter fed into proper depth by hand. A suitable vise on the conveyor track allows the thread to be sized by hand tap before going into the base threading machine.

Owing to the greater amount of work on the base thread, two duplex Bertram machines are required to handle the volume of work which is done by the nose threader. The operation is very similar, the principal difference being in the method of holding the work. Conoidal plugs with threaded rods are placed inside the shell noses and engage with tapped hand wheels at the back end of spindle. The milling cutters are carried on independently adjustable blocks mounted on the cross slide of carriage, which in turn is fed along by lead screw. Hand tapping to size, followed by cleaning completes the shell for preliminary inspection.

After passing inspection the shells

FIG. 12. VIEW OF BAY SHOWING TRACKS FOR WORK AND PRELIMINARY INSPECTION CRIB.

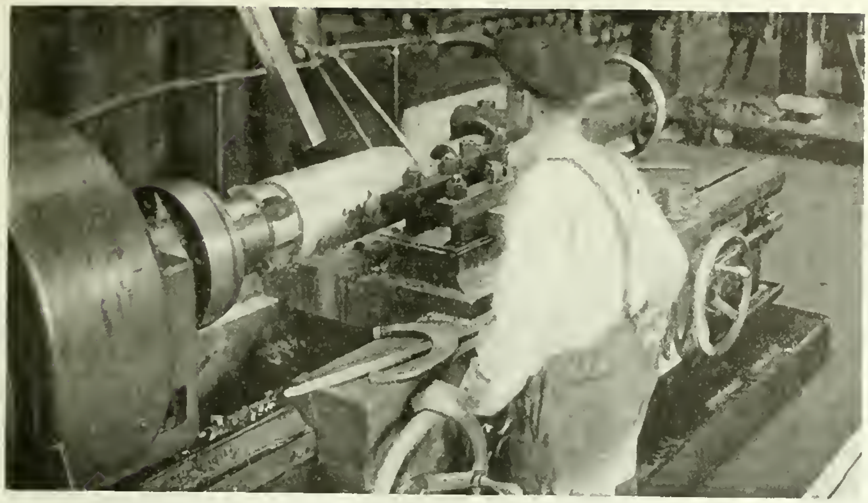

FIG. 14. BAND TURNING MACHINE SHOWING TWO TOOLS ON SLIDE BELOW WORK.

receive the adapter which are tried into place by hand, and in nearly every case go within half an inch of being home. This is due to the very close limits within which the threaded work is held. A satisfactory fit having been assured, the adapter is withdrawn, coated with cement and inserted for good, being driven home in a special driving machine built by Root & Van Dervoort. This consists of a suitable framework at one end of which is a pneumatic clamp which holds the shell in line with the driving spindle. The spindle is geared up to a $4\frac{1}{2}$-in. belt, and has a sliding head with two pins which engaged the holes in the adapter. The operator causes the head to follow the adapter by pedal-operated toggle gear, and maintains it in engagement until the belt slips. A characteristic ringing sound when struck with a hammer indicates that the adapter is hard down in the recess.

Banding and Facing

Banding follows immediately, being accomplished in a twelve-cylinder press with four-throw pump, the entire outfit being supplied by the West Tire Setter Co. Heating the bands is resorted to, to insure a perfect fit on the threads and a proper filling into the undercuts. A gas-fired furnace with capacity for three bands, keeps pace with the work, the bands having a temperature of around 1,200 degs. F., which combined with the cooling effect of the dies gives a desirable annealing to the copper in situ.

The adapter joint is riveted and faced-off in suitable engine lathes having special tool boxes fitted to cross slide of carriage. These tool boxes have a pneumatic riveting hammer of ordinary type securely clamped to a cradle, provided with a spring mounting which absorbs excessive vibration from the hammer. One revolution of the shell with the hammer in operation serves to close up the adapter joint in good shape, after which the tool box is traveled across, bringing a facing tool into action which in turn is followed by a radius tool for rounding the corner of the base.

Varnishing and Baking

The nose is finally tapped to gauge and the bevel seat reamed with a special cutter supported on an expanding arbor in the threads, thus insuring the seat being true with the threads. After a thorough cleaning with gasoline and a blow-out with air, the varnish is applied with an Eclipse air brush, a protecting bushing being inserted in the nose to keep the varnish out of the threads. This method gives a very even coating with a minimum amount of varnish which allows of the shells being baked right away without loss of time due to draining off excess varnish.

The type of oven adopted is that in which a separate heating element is inserted in each shell, the elements being suspended from a hood, which is lowered over the shells. Nine shells are baked at a time in each unit, the base having sockets which space the shells accurately to correspond with the heating elements. Six units suffice to handle the output, the time of baking being reduced to a minimum through the method of applying the heat.

Band Turning

The shell is chucked in the hollow spindle of the band turning machines, which have a roughing and a finishing tool arranged to travel toward the front of the machine, sizing and forming the band as they pass underneath. These Root & Van Dervoort machines have the cutting edge of the formed tools shaped away at an angle so that the cuttings leave the tool in a backward direction, being deposited behind the machine out of the way of the operator. After turning, the tools are traveled back and a tool rest in front brought into action which bevels the right side of the band, cleans up the opposite side, and sizes up the square groove in the middle.

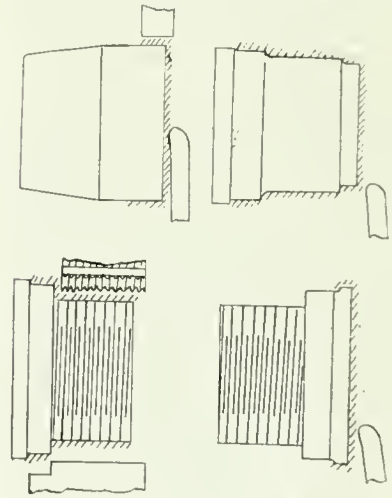

FIG. 15. OUTLINE OF OPERATIONS ON ADAPTER.

Weight Checked

The shell is now cleaned out with air, and passed over scales for the first and

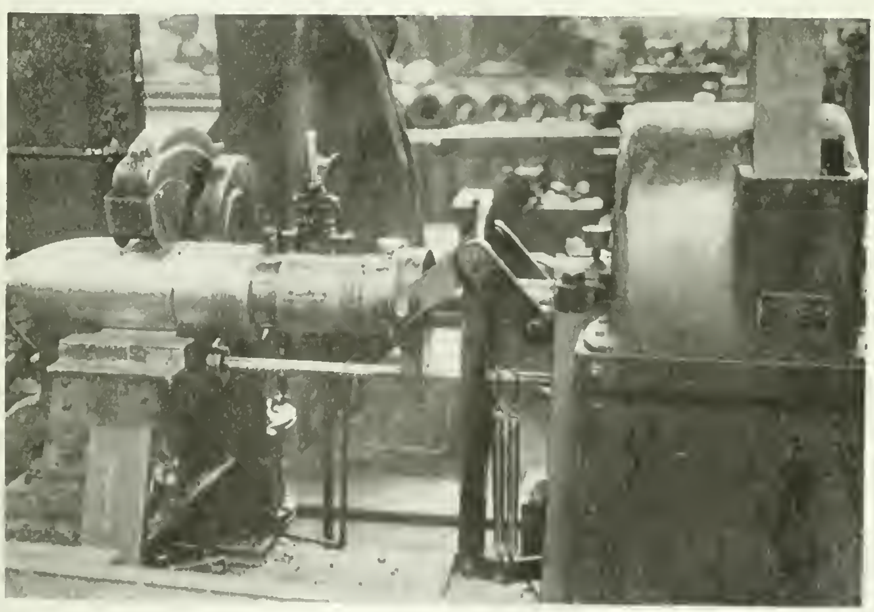

FIG. 16. ADAPTER DRIVING MACHINE.

last time during manufacture. The finished weight of shell is 177 lbs + 14 ozs., and — 1 lb. 12 oz. A number of shells taken at random showed no appreciable variation above or below which proved that not only could suitable dimensions be determined, but that they can be adhered to with a high degree of accuracy dispensing with much time, which is considered necessary in adjusting weights both in the course of manufacture and also at the conclusion.

The concluding operations are well-known to most of our readers, and call for no special reference. The remaining space shown on the layout is occupied by the final government inspection, a Brown Boggs marking machine, and boxing operations. After boxing, a number of shells are piled on suitable sized platforms and transferred by overhead traveling crane to a freight car on the track shown.

Adapter Machining

A few points in the adapter work are of interest, one being the fact that standard types of machines are used throughout, and another, the method adopted of insuring that the threads and joint face of flange are absolutely true with each other.

The work is divided into five stages as in Fig. 15. Operation No. 1, is done in Hall pipe machines, with two tools which approach each other so that the finish of the operation finds them in the position shown. Operation No. 2, is done in engine lathes which chuck by the previously machined diameter. Operation No. 3 is done in a small drill press with universal chuck and locating device. Operation No. 4 is done in engine lathes fitted with a thread milling attachment on the back of the carriage and a special slow speed drive to spindle through gearing at back of head stock.

The machines used for this purpose are C.M.C. 26 in. heavy duty lathes. Considerable rigidity is necessary to secure a satisfactory thread, close adjustment of the spindle bearings and carriage being maintained at all times. The formed turning tool which finishes to size is accurately set up to produce all diameter parallel, and face the flange perfectly square with the body. The milling of the thread follows without the work being rechucked so that the required accuracy is obtained continuously, and with no call for excessive skill or care on the part of the operator. Operation No. 5 consists of chucking by the threaded body and facing off the excess material on the base, leaving sufficient metal to clean up comfortably after riveting the joint in place.

FUTURE OF CANADIAN IRON AND STEEL

THE future of the iron and steel industry in Canada was the subject of a symposium at a session of the Canadian Mining Institute convention held recently. What has been accomplished to date was made the basis for remarks as to the prospects for the future, and there seemed to be a general inclination to believe that the industry in Canada needed Government bounties or tariff protection, to enable it to complete successfully with the United States.

Corbett F. Whitton led the discussion by a paper which named all the various companies interested in the iron and steel industry in Canada. Each plant was described with what it manufactured, and the special advantages of each over its competitors were shown. At present the iron and steel industry of Canada is dependent almost entirely on supplies of iron ore from outside sources. On the Eastern Coast the supplies come from Newfoundland, while the Algoma Steel Co. and the Steel Company of Canada, Hamilton, Ont., get their supplies from the United States.

On account of cheap water transportation from Newfoundland, and the coal readily available from the mine, the companies in Nova Scotia were favorably situated. Metallurgical coke for smelting purposes was the essential thing in the iron industry, and with both these advantages at Sydney, the Nova Scotia Steel & Coal Co. and the Dominion Iron & Steel Co. should be able to produce iron just as cheaply as anywhere in the world. The Algoma Steel Co., was built primarily for the purpose of manufacturing steel rails at the Soo where iron ore and coke could be assembled from American ports by reason of the cheap lake transportation, and where the company would be favorably situated to command markets both East and West in Canada.

On account of changing conditions in Canada and the possibility that there will not be railway construction as in the past, the Algoma Steel Co. is going into the manufacture of rolled steel sections, and extensions to the present plant for rolling structural steel for building, bridge and other purposes up to 24 or 36 inches, are contemplated. There was little doubt but that other companies were considering similar extensions.

D. H. McDougall, of the Dominion Iron & Steel Co., pointed out the importance of the iron and steel industry to Canada, it being the basic industry on which all metal products depended. Everything possible should be done to encourage such an industry.

Magnetite Deposits

R. R. Hedley, from British Columbia, said that his province had no iron and steel industry, but that there was a large market there for iron and steel products. The drawback against establishing an industry there was the uncertainty of getting a supply of suitable iron ores. There were large magnetite deposits, but no large hematite deposits. The magnetite deposits, however, sometimes contained as high as 1½ per cent. of copper. It would be possible by the electro-magnetic separation of the iron from the copper to recover both. That should be profitable, especially in consideration of the fact that the Vancouver Island coals were suitable for the manufacture of metallurgical coke. Already 3,000 tons are produced monthly to be used in connection with the smelting of copper in British Columbia. Everything possible should be done, in his opinion, to encourage the industry in British Columbia.

One speaker, in the general discussion, said he did not want to talk politics, but he did not think that the Government had fully protected the iron and steel industry on account of the fact that the tariff was not made general, but particular in character. As an example he said that plates for ships, construction and boilers were practically admitted free while there was a duty on other plates. One of the essentials in the manufacture of iron and steel products was a large output, and if certain steel plates came in free it reduced the market of Canadian companies for steel plates.

A gentleman from Deseronto said that he represented the smallest steel industry in Canada. In Deseronto the problem was to get suitable ores. The ores which the Deseronto concern used or experimented with, came from the Moose Mountain district in Northern Ontario, and were magnetites. The present methods of treating magnetite were too costly, and he thought that the Government should carry on investigation so that the iron and steel industry could be established on the basis of using Canadian ores.

ELECTRICAL PROCESSES IN METALLURGY

A MORE than usually interesting address was given last week, at the Shaughnessy Building, Montreal, by George M. Berry, chief chemist of the Holcomb Steel Co., of Syracuse, N.Y., and inventor of the process by which hydro-electric power has been commercially applied to metallurgy. The lecture had been arranged by Arthur D. Little, Ltd., under the auspices of the Canadian Pacific Railway Co., with a view to showing what could be done to use undeveloped water powers in Canada to develop other industries, and especially the electrical production of high grade steel. J. S. Dennis, assistant to the president of the Canadian Pacific Railway, introduced Mr. Berry, there being an audience that taxed the capacity of the room.

In his address Mr. Berry was decidedly technical, illustrating his talk with a series of lantern views, showing the development of the electric furnace. He emphasized the fact that the steels required at the present day on this continent could not be made here, were it not for the electrical furnace, owing to the absence of suitable clays and graphites for the ordinary production of crucible steel.

These electrical processes, he demonstrated, had really saved the situation in Canada, especially during the past two years.

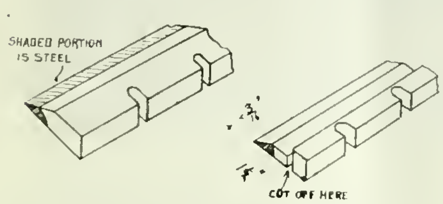
A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

SAVING MONEY ON PLANER KNIVES

By H. Middletown.

EVERY wood-working establishment that boasts one or more planers or jointers has some worn out knives laid up on a shelf or in the pile of scrap metal out in the back yard. These knives, or blades, have been worn to the limit that

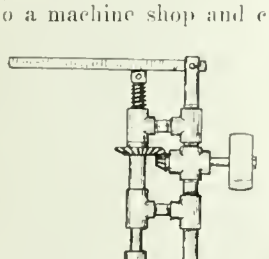


SAVING MONEY ON PLANER KNIVES.

it is possible for the bolts in the head to hold them securely but not one in twenty is worn to the limit of its steel cutting face as an examination will show. The knives in this condition are as shown in the drawing which shows that although the bolt slots are short, there is still a goodly portion of the steel left.

Now in addition to the worn out blades, there is usually a pair of good ones with every one of the old style heads that have been taken out to meet insurance and factory regulations and which have been replaced by the round, safety heads. These round heads, as everyone knows, take a thin flat knife which is all steel and an average size of which would be, say, 3/16 in. × $1\frac{1}{2}$ in. Now, instead of buying these new knives, they can be made out of the discarded ones at a material saving.

A discarded knife 24 in. long would be from $2\frac{1}{2}$ in. to 3 in. wide and can be taken to a machine shop and cut to the



THREE DOLLAR SENSITIVE DRILL.

3/16 in. × $1\frac{1}{2}$ in. size in a few hours. The way in which they are cut is shown in the drawing. Note that the metal is planed off the "back," leaving the 3/16 in. of composite cutting edge. Then a slotting tool severs the notched portion and leaves a good new blade. This extra notched portion gives a width of surface for clamping on the machine shop planer which is very handy and contributes to a marked degree to the low cost of the job. If the shop has a milling machine of No. 2 size or larger, the work can be done on it in even less time and the cost of altering a pair of 24 in. knives should not run over $2.25 which is a fraction of the "new" price. If more than one pair of old knives are available, the lot should be done all at once and get the benefit of quantity prices.

Some good wood men claim that the old knives had better steel in them than modern ones. If so, this is the way to reclaim it. At present the quality of steel might not be up to the old standard — neither are deliveries at all prompt—all this favors recutting. After recutting, the knives will be found curved, but they are easily straightened on a block.

A THREE DOLLAR SENSITIVE DRILL

By D. A. Hampson.

MY friend Charlie Marks had been running a country blacksmith shop about a year when I dropped in to see him. In that time, his trade had increased—also he had accumulated a creditable pile of scrap—and he told me he wanted to buy a post drill; this drill was to be power driven, for he was up to date, and already had a motor to drive the forge blower—cheap electric current being available in the village.

Now a country blacksmith, like the minister, must take his pay in the coin of the realm and also in commodities, i.e., vegetables, cord wood, labor, and scrap iron; included in this latter item had been an old chainless bicycle, and as my wandering eye took in this relic, the pair of bevels at the crank suggested the right angle drive of a drill press and around them, I mentally built a machine, that for cheapness and perhaps crudeness, combined with utility, would be hard to beat. Charlie was enthusiastic over the scheme and furnished me with the bevels and a shaft from the bicycle, a twelve-inch pulley, and a chunk of cast iron that was to be the base or table. "I'll furnish these things and will forge the feed lever and you can do the rest," he said, as I left.

How the machine looked may be gathered from the drawing. The pipe fittings and the nipples came from a plumber's shop and cost $1.47. These fittings were assembled, the shaft laid in, and the spaces filled with babbitt which Charlie had dug out of two old saw bearings. The base was pipe tapped, the pinion shaft turned to a shoulder, the spindle keyseated and a hole drilled for his 3/8-in.

FIG. 1. STEEL BALL-BEARING GRAVITY ROLLER BOX CARRIER OF 1% GRADE.

straight shank blacksmith drills. The labor involved took three hours at sixty cents, so the machine stood Charlie in a grand total of $3.27. And it really did good work and was quite rigid. The collar which reinforced the spindle, the spring return to the spindle, and the feed were added after the machine got in the hands of the blacksmith.

CONVEYOR EQUIPMENT IN CARTRIDGE CASE PLANTS

By M. J. Anderson*

THERE are many interesting operations performed as well as devices employed in connection with cartridge case manufacture, and the conveyor systems and equipment used in these plants for handling their commodity is among the most interesting from an engineering point of view. Due to the high cost of labor and its apparent scarcity, the subject of conveying and labor saving machinery has come into prominence, and is being given due consideration by up-to-date shop executives.

Conveyors are used to-day to a far greater extent than ever before, and the munitions manufacturers were quick to realize that large savings in labor time, and space, could be made by their installation. The types of conveyor being adopted for munition plants indicates that the subject has been thoroughly canvassed with respect to adaptability, flexibility, and economy of space, also relative to initial cost and maintenance. Whether in a billet cutting plant, forge shop, fuse shop, powder plant, cartridge case or other branch of munition manufacture, conveyors can be seen speeding up production.

With a combination of gravity and power conveyors working in conjunction, receiving and discharging automatically from one to the other, several handling problems have been solved. A minimum amount of floor space is required, and the surface is often used for storage or as a working table, goods being moved along as required from one operator to the next. The gravity carriers are made up in sections and are readily portable and can be used at different points or by adding on or taking off sections along main line, various positions can be reached. By using one main line of carrier down the centre of a building and using curves and branch portable lines down aisles, large rooms of stock are quickly filled or emptied. Manufacturers are often limited to floor space. Goods are loaded direct to incline power sections or elevators that raise them to required heights, and discharged onto lines of gravity conveyors. These convey overhead any required distance and discharge on end with chutes to floors or tables.

*Superintendent, Canadian Mathews Gravity Carrier Co., Toronto.

FIG. 3. STEEL BALL-BEARING GRAVITY WHEEL BOX CARRIERS OF 4% GRADE.

FIG. 2. SYSTEM OF STEEL BALL-BEARING GRAVITY BOX CARRIERS LOADING CARS.

There are many combinations of arrangement possible, and complete conveying systems are fitted to suit the peculiarities of different conditions. To meet these conditions many ingenious designs and variations of construction have been required, some of them being both unique and interesting to both the casual observer and the engineer. The gravity carriers here described are of two types, wheel and roller.

The wheel type illustrated in Fig. 1 is made up of two rows of steel rails riveted to cross and lateral braces, the rails being spaced a required distance apart to suit the package to be handled. At close centres on the outside of these rails, ball bearing wheels are bolted, making two continuous rows of wheels the length of the conveyor. These wheels are about two and three-quarter inches in diameter by five-eighth inch face and revolve on a nine-sixteenth inch diameter cone which makes it very light running. It can be readily seen that these make a very light running apparatus that requires very little grade to operate and in many cases requires only from two to three foot fall in one hundred feet of carrier. Any number of sections can be connected to make continuous lines of any desired length, both straight and around curves. With these sections of carrier and the additional use of power elevating sections and chutes, many combinations have been worked out to meet varying conditions. Such a type of carrier is used extensively in conveying boxes with metal or other bands around the edges, and is adapted to the handling of cartridge case boxes. These boxes ride on the conveyor crosswise with the ends projecting out four or five inches outside the rows of wheels so that the bands at ends do not come in contact with, or interfere in any way with the conveying surface. In the same way the middle band, if there is one, passes between the rows of wheels. These carriers are in extensive

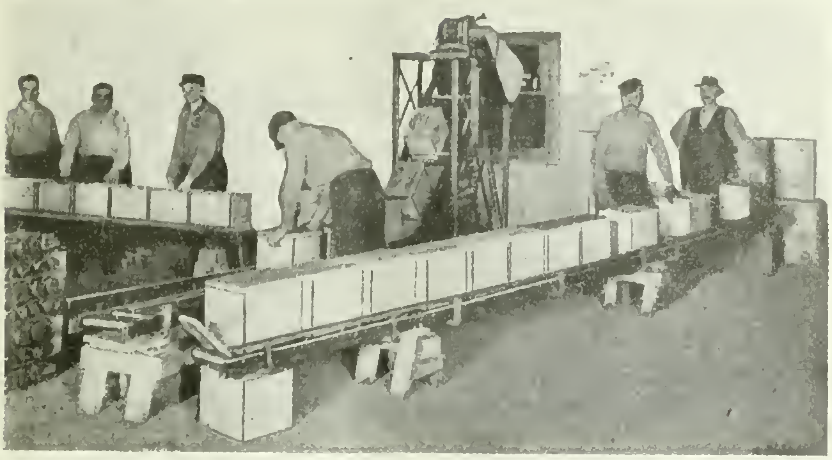


FIG. 4. CARRIERS AS INSTALLED IN A TEA BLENDING ESTABLISHMENT.

use in various plants manufacturing cartridge cases.

The roller type of gravity carrier illustrated in Fig. 2 is constructed along more substantial lines than the wheel type and because of its construction is adaptable to a wider field in the variety of commodities that can be handled on it. It is employed in nearly all branches of munition manufacture, forging shops, machining shops, cartridge case, fuse and powder plants being among the more extensive users. This is constructed of ball bearing steel rollers of any required length set in a securely braced frame at any suitable spacing to accommodate the article to be conveyed. With this carrier, like the wheel type, many combinations have been worked out, and many very interesting systems are installed. These are also extensively applied to handle cartridge case boxes, and lines of these carriers are used as a working bench for the final filling of boxes and screwing down the covers. Cartridge case manufacturers were among the first of the munitions plants to see the advantages of gravity conveyors, and many shops are to-day equipped with extensive systems of gravity and power conveyors.

Unloading cars of empty boxes to the box storage building is one of the first items of consideration and the time required to empty a car has been cut in two. Portable sections of wheel type gravity carrier are used and when the car is set, a line of these carriers is set up from the car door to the point in the building where boxes will be piled. By means of a coupling device these sections are quickly hooked together and are set up on adjustable stands or jacks. Setting up the carrier requires but very little time. Boxes are placed on the carriers which move them away as fast as two men can place them on and are taken off at the other end and piled by two or three men. When one section of the storage space is filled up, the carrier line is shifted, and by taking off or adding additional curves and straight sections any part of the available space can be reached. This method has many advantages over trucking, in that it saves the time of loading and unloading trucks and the time required for returning, also the wear and tear on floors and trucks. These carriers can be run down narrow aisles and can make turns where trucks could not be used, allowing more floor space for storage.

The next operation with the conveyors is getting these boxes from the storage to packing and shipping department. The wheel type of carrier is also used for this. A main line of conveyor is permanently installed from the storage room to stock pile in shipping room, and, to this, connections are made in the storage building by means of portable sections and stands to meet any required point from which boxes may be required. Boxes are loaded on to conveyor and are taken off in shipping room where quantities are stocked to be used as required. These conveyors are often filled up with boxes and are a means of storage for immediate requirements. As boxes are taken off the end, the whole line moves up so that it can be always kept full from loading end. This line of carrier leads to packing bench where finished cartridges are placed in for shipment.

In the shipping room are stock piles of finished cartridge cases in trays ready for the final stamp before packing. Two lines of carrier lead from these stock piles to stamping block where each cartridge case is taken out and given its final stamp. The lines are continually filled up with trays, each of which holds about twenty cases. There is a line of roller carrier from this stamping block through a door in the building across the platform to car at siding. As fast as these cartridge cases receive the final steamp they are packed in boxes and are ready for the covers. The packing is done at the start of this line of carrier and the covers are put on by operators along each side. The roller carriers are used for this work, because they afford a working table for the workmen and are more substantial in their construction. Supports on castors are put under the sections outside of building leading to car. With this method of handling boxes and trays, cartridge cases are handled for shipment with remarkable precision and speed, in a minimum amount of time, and the economical use of space.

There are a number of other more or less minor operations facilitated with these carriers, one of these being the conveying of trays from inspectors to stock piles in shipping room. Under different conditions it has been found necessary to use power elevating devices to raise boxes where various elevations are required. Fig. 3 shows a portable adjustable incline elevator used for this purpose. This receives and discharges automatically in connection with either type of gravity carrier and is used to great advantage where conditions require changes in height and location of stock piles or cars.

FIG. 5. CARRIERS DELIVERING TO INCLINE AUTOMATIC ELEVATOR LOADING CARS FROM STOCK PILE.

There are other branches of munitions manufacture that have used gravity conveyors more extensively than that of cartridge cases, but considering the nature of the product and methods of production, the different plants are applying them proportionately wherever their use will mean increased production and a saving of time and labor.

GLOBE VALVE EXPERIENCES

By J. E. McCormack.

WITH regard to globe valve experiences the writer likes to have two globe valves on the steam supply pipe to the injector or pump, just on the same principle as one likes to have a globe between the check valve and the boiler, or a stop cock between the boiler and the throttle, because if one fails he has the other to "fall back on," as the phrase goes.

Some years ago he was in charge of one of those plants having only one globe between the injector and the boiler steam space. This globe was of the type in which the face was an internally threaded member and was screwed onto an externally threaded member which in turn fitted behind a shoulder on the valve stem. All went well for a few weeks, then one morning the face dropped from the stem and lodged in such a way as to render the injector inoperative. As there was no other feed-water system installed, and only one boiler used, there was no option but to get the steam off, fix the valve, and raise steam again, thus causing a delay involving more or less financial loss to the proprietor, and which could have been avoided had there been another valve next the boiler with which to shut back the steam while the defective one was being overhauled.

Choosing a Valve

It was then decided that an additional valve should be in for meeting such an emergency should it recur, and the writer was asked what make of valve he would prefer. It was only natural that he be expected to name what was then the valve most advocated by old hands, but he was young, enthusiastic and self-willed. He wanted one which, for holding the face in place, did not depend on a nut or screw which might come loose and drop the face, or, if made too tight, would perhaps stick, and refuse to budge without breaking. A valve answering to these requirements had been described in your publication. The local dealer did not stock them, but a look or two through the advertisement section disclosed the whereabouts of a sales house, and a few different sized valves and discs were ordered by letter. The only tool required when changing the discs is a wrench that will remove the bonnet; this done the old disc can be easily removed from the stem by hand and a new one slipped on. When the bonnet is returned to its place it is impossible for the disc to get out of position.

Emergency Babbitting

After a time it was found that the supply of discs for one size of these valves was nearly exhausted and to make it hold out a little longer (owing to no local dealer stocking them as aforementioned), the writer took a cue from the soft metal faces of some lubricator plugs. The old asbestos face was dug out and its place filled with melted lead. This lasted for two days, at the end of which time it had squeezed out too much. Melted babbitt metal was then tried, and as it gave very good service it was used on this size of valve for some time. An acquaintance tried the babbitt on a make of valve which used a nut to hold the face in place and effectively locked the nut by pouring in enough metal to entirely cover the said nut.

Although the writer was, and is yet, well pleased with his chosen make of valves, he has known them to be criticized by other operators, each of which had a preference of his own for some particular make, but on one occasion when talking with an engineer about valves in general, the engineer remarked, "I like those —— valves. For one thing, they are a valve you are never stuck with. The discs are easily changed, yet won't come off unexpectedly, and if you should happen to run out of discs you can remove the old face, pour in some babbitt, true it up a bit and go on again." Now, my object is not the boosting of any particular brand of valves, but what I want to impress is that this babbitt habit has helped out of difficulties at times and a few men have begun to look to it as one of their stock emergency measures. With this fact in mind we are ready for another experience, which came to the writer's knowledge just recently.

Conditions Must be Studied

The globe on an injector steam pipe was bad and no proper face for that make of valve readily procurable at the time, a few days' delay being normally unavoidable under existing circumstances, and so the operator tried the babbitt scheme for the first time. His boiler was an upright one with this globe placed close to it. Before being in use long his injector balked and investigation proved that some of the babbitt had melted and been carried down into the injector steam jet. Evidently some of the metal had also lodged in the elbow, for after a reliable face had been inserted the injector was twice put out of action by plugging with babbitt. The brand of babbitt used may have been rather easily fused, but the writer's personal theory is that since the boiler was an upright one, the steam became at times sufficiently super-heated to melt babbitt. Anyway, this latter experience proves that though some have been helped by thus using this metal it may perhaps be worse than useless wherever any degree of super-heat may even possibly exist, and "by the same token," when trying out only one valve of any make and in comparison with other valves in service it may, if placed as above-mentioned or in any other position where super-heat may get to it, appear to use softer discs than other valves when in reality it is being put to a more severe test than is the valve or valves, it is being compared with, yet without the operator suspecting that such is the case.

INDUSTRIAL DEVELOPMENT OF EASTERN CANADA

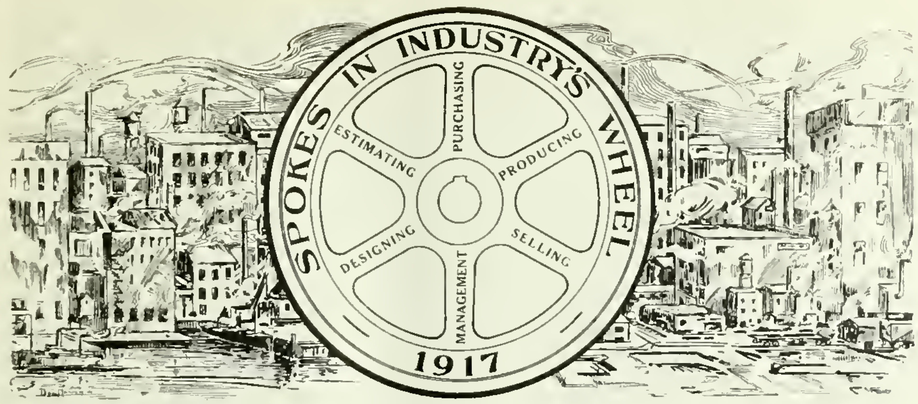
THE industrial development of Eastern Canada is continuing at a remarkable rate. Many new industries are locating in this territory each month; big, new plants are being erected and many of the established concerns are making large additions to their factories. Wm. P. Fitzsimons, Commissioner of Industries, Grand Trunk Railway System, states that new plants representing a capital investment of nearly $12,000,000 have been placed along the company's lines within the last twelve months. These new industries number approximately seventy-five and will employ more than 10,000 hands when in full operation. An additional $5,000,000 was spent in that period in extensions to manufactories, providing work for another 4,000 men.

Among the largest of the industrial concern to secure locations served by the Grand Trunk, during the past year, were the Dominion Sugar Co., at Chatham, Ont.; British Munitions, Ltd., Montreal; St. Catharines Steel Metal Co., at St. Catharines; Kellogg Toasted Cornflakes Co., at Toronto; Dominion Dustless Sweeper Co., at Peterboro; and William Kennedy & Sons, Ltd., at Collingwood, Ont. These six plants alone represent an investment of approximately $3,000,000.

Among the plants under construction is a large refinery at Port Colborne, Ont., for the International Nickel Co. of New York and New Jersey. The building of this plant is of national importance, not only because of the large investment involved amounting to several million dollars, but because it places within the Dominion the refining of invaluable nickel ore, and the distribution of the finished nickel, work which had been previously done outside of Canada.

Since 1910, five hundred industries with a total investment of about $100,000,000, have been located along the Grand Trunk Railway. This splendid work in building up Canada's industries has been greatly facilitated by the traffic department of the railway, to which the Industrial Commissioner and his staff are attached. The Grand Trunk traffic men, under the direction of Vice-President Dalrymple, are indefatigable in their efforts to help manufacturers find suitable locations.

The Canadian Steel Corporation, Ojibway, Ont., have not entered into a contract for power with the Hydro-Electric Commission of Windsor, Ont., as stated in a recent issue. The contract referred to was made by the Canadian Salt Co., Sandwich, Ont.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

PERCY OSCAR GORDON JANES

EQUALLY important as the generation of power is that of its transmission, and just as there is in the former a wide variety of appliance and mechanism employed, also large opportunity for the exercise of individual genius and expert skill, like conditions may be said to generally prevail in the sphere of the latter. In a word, power generation and power transmission, as regards improvement and development, should go hand in hand, otherwise the efficiency achievement of either becomes to a lesser or greater extent curtailed if not nullified. It is quite apparent, however, from a close study of power engineering that both departments are forging ahead and keeping step, so to speak, by taking full advantage of each other's latest creations. The subject of this personal sketch, as will be noted, is largely interested in the transmission feature — to wit, ball bearing equipments.

Percy Oscar Gordon Janes, sales engineer and manager, the Canadian S K F Company, Ltd., 47 West King Street, Toronto, Ont., was born at Bury, Lancashire, England, January 31, 1885, his father being William Alfred Janes, and his mother, Emma Milsom. He was educated at the day and technical schools, Bury, also attending the evening classes at Salford Technical Institute. He afterwards took a six years' engineering course at Manchester School of Technology—part day and part evening, passing the Mechanical Engineering examination of Manchester University as an external student.

At fourteen years of age he became apprenticed to Robert Hall & Sons, Ltd., textile engineers, Bury, graduating from the shops to the drawing office. Five years later he joined the drawing office staff of Galloway's, Ltd., Manchester, in which capacity he acquired considerable insight and experience relative to the design and construction of high-grade steam engines of various types. After concluding another five-year term at Galloway's, he became associated with Daniel Adamson & Sons, of Dukinfield, near Manchester, occupying the dual position of draughtsman and superintendent of outside erection in engine department; being later transferred to the Rateau steam - turbine branch of the firm's activities, with charge of the turbine drawing office.

The next move of our "Spoke" was

PERCY OSCAR GORDON JANES.

overseas to Canada, for in 1911 we find him on the staff of T. Pringle & Son, consulting engineers, Montreal, as mechanical engineer and draughtsman. With the lapse of twelve months, by which time he had not only found his "bearings," but had become alive to his adopted country's opportunities, the desire for personal enterprise had taken hold of Gordon, hence his establishment of a business partnership under the title of the Engineers' Representative Co., of Montreal, to act as sales agents for several English concerns, among whom was the Skefko Ball Bearing Co., of Luton, Bedfordshire; marking, as a result, the introduction of the S K F ball bearing to Canada.

The demand for this type equipment began to increase quite rapidly right from the start, and finally became such as to tax the financial resources of the partnership. The Canadian Fairbanks-Morse Co. stepped into the breach, however, by mutual consent of the various interests, and to enable our "Spoke" to transfer his services to the C.F.-M. Co. as specialist on Skefko bearings, the Engineers' Representative Co. was dissolved.

In June, 1915, Gordon became assistant manager of the machinery department of the Canadian Fairbanks-Morse Co., becoming manager towards the end of the same year. Some twelve months later he went back to his "old love," the Skefko bearing, the Canadian S K F Company, Ltd., with showrooms, as already stated, having been organized to take care of all bearing business offering in Canada, with our "Spoke" as manager. Aside from his heart being well set on the great possibilities of a Canadian market for ball bearings, and to use his own words, "my special weakness for something moving," same being exemplified in his show room window displays, he found time while machinery manager of the Canadian Fairbanks-Morse Co. to design and develop the boring lathe for 6-inch H.E. shell, built by the Reliance Machine Co., Toronto.

Mr. Janes is some politician, to wit, a strong Imperialist; and in religious creed, Church of England. He is a member of the Engineers' Club, Toronto. It will naturally be inferred from the preceding sentences that he is a benedict, the more so in view of his limited club activities. Miss Constance Boon, of Manchester, England, became Mrs. Gordon Janes on August 30, 1913, the marriage ceremony taking place in St. James' Cathedral, Toronto. The family residence is at 21½ Balsam Avenue, Toronto. Walking and cycling have always been Gordon's special recreations, although the opportunities to take advantage of them in Canada are scarcely so ready to hand as were those of the Old Country, the major portion of which he has covered on foot and on the bicycle when touring for pleasure. Since settling in Canada, business activities have led to his becoming more or less familiar with Eastern Canada, as also of a fair slice of the United States.

Our "Spoke" looks for great developments taking place in Canada, following the war, especially in engineering and its allied industries, all of which will, however, call for higher grade skilled help, and, therefore, necessitate an enlargement of the facilities for procuring technical education. Trade and technical papers will in the nature of things become factors of the greatest importance in assisting and consolidating progress towards substantial achievement. "Since starting my engineering career," says Mr. Janes, "I have followed closely the latest developments through these mediums.

MACHINISTS' INSTRUCTION COURSE—XVI.

By J. Davies.

IN threading taper-work the tool should be set at right angles to the axis of the work, the same as for parallel work. If the centre is set over by means of the tail-stock it will give an incorrect pitch and also a drunken thread. When the dead centre is set over, the work will be in the position of the dotted lines Figure 56a. The work would have to be set over so that the face would be parallel to the centre lines A.B. Suppose the piece to be 3 in. long, and is to be threaded 10 threads per inch. Since the length of taper, measured on the slope, is greater than the true length of the piece measured parallel with its axis, it will require more than 30 revolutions to carry the tool entirely over the work, consequently there will be more than 30 threads on the piece, and it will not measure up exactly 10 threads per inch.

Taper-work should always be done by the taper attachment. When a thread is cut by setting over the tail-stock, owing to the angularity of the tail of the lathe dog, it does not travel at a uniform speed with the lathe face-plate. The tail of the dog can be observed to slide in and out the notch of the face-plate. When this condition takes place, the thread cannot be a uniform pitch.

Inside Threading

Use the threading gauge for setting up the tool, and see that the shank of the tool is approximately parallel with the work so that the back of the tool wil not rub against the first thread before the point gets through the hole. In threading long small holes the biggest trouble to contend with is the spring of the tool. Many lathe hands make the cutting edge of the tool level with the top. This means that the whole of the tool must pass through a circle equal to half the diameter of the hole (see Fig. 57). If the cutting edge of the tool is made to come in the centre of the shank also as shown in Fig. 57, a much stiffer tool can be used.

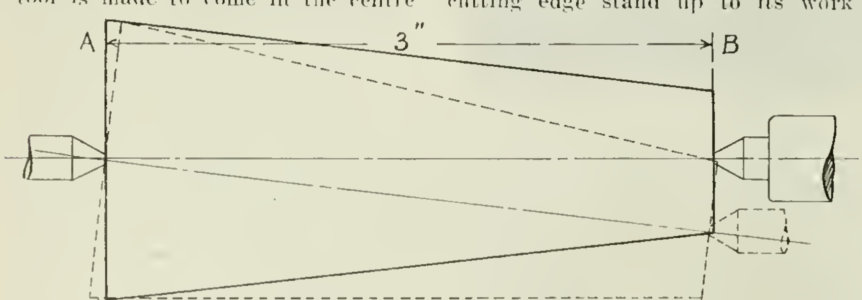

FIG. 56a.

In cutting threads in very long sleeves or bushes, the work is sometimes fastened to the carriage of the lathe and the tool is carried in a parallel bar between the centres of the lathe. While this method gives excellent results for very long threads such as nuts for rolling mill housing, etc., it is open to the objection that for every cut the tool must be carried back to its starting place by means of a reverse belt, or else the tool must be removed from the bar.

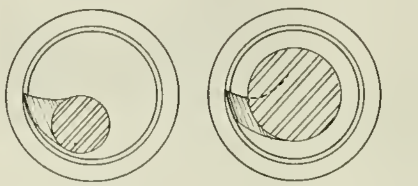

FIG. 57.

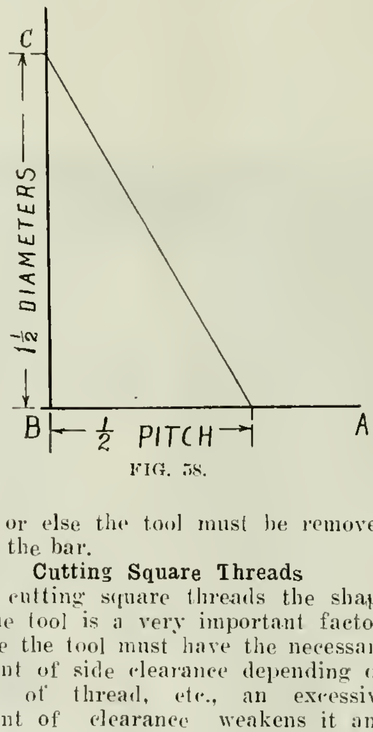

FIG. 58.

Cutting Square Threads

In cutting square threads the shape of the tool is a very important factor. While the tool must have the necessary amount of side clearance depending on pitch of thread, etc., an excessive amount of clearance weakens it and makes it liable to break, neither will the cutting edge stand up to its work so long as when correctly designed and made.

The following rule for the side clearance of square thread tools gives general satisfaction in practice:—Draw two lines AB, BC at right angles to each other (Fig. 58). Make BC equal in length to 1½ times the diameter of the screw to be cut. From B mark off a length along BA, equal to half the pitch and draw a diagonal line connecting the two lengths. The diagonal line will give the angle or rake of the tool. Having obtained the angle of side clearance for the tool, mark off a piece of tin for a template, or make a gauge as shown in Fig. 59, which is also useful to the blacksmith in making square thread tools, as in nine cases out of ten, he just guesses the amount of clearance required, with the result that there is a lot of unnecessary filing to do. A tool for finishing square threads should be made very slightly thicker at the root than at the point. This enables the nut to enter more readily, and where the tool is sharpened by grinding the front cutting edge, the sides can be touched up. A tool made this way smoothes up the sides and can be ground quite a few times and still retain its original size.

Shaper and Planer Work

The shaper, or the fitter's friend, as it has been sometimes called, and the planer are so nearly akin, that most of the methods and principles are applicable to both; in order, therefore, to avoid any needless repetition, we will consider them together. To enumerate the different types of machines would be a waste of time; a careful examination of the particular machine that one is called upon to operate, will give more useful information than a general description of the different types.

Much of the same work can be done on either shaper or planer, the same methods of securing the work and the same kind of tools being used. The shaper is best adapted for light work and short cuts, or where a cut of a definite length is required, such as cutting a key seat in the end of a shaft, or cutting up to a square shoulder, as the length of stroke of a planer is not positive and cannot be relied upon within an inch. Most shaper work is held in a vise bolted to the shaper table, the vise being usually graduated so that it can be set to any angle.

The first consideration in planer or shaper work is to decide if the work can be done in one setting. Never move or reset a job if it can be avoided. Suppose a blanking die (Fig. 60) is to be shaped so as to leave a margin of steel around the hole about ½ in. wide, this being done to reduce the work of subsequent grindings. This could be done at one setting by swinging the vise around to suit the different angles and taking the finishing cut without moving the tool up or down.

In shaping a square piece of metal,

shape two sides first, if possible, then turn your vise around 90 degs. for the other two. It is obvious that if a square

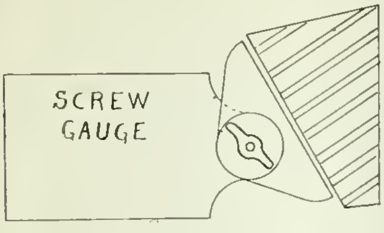

FIG. 59.

block is to be planed square and true all over, this method could not be used, and it would be necessary to reset the job for each surface. In this case, rough the work out all over first, and after one face is finished care must be taken to see that the finished face is held squarely to the jaw of the vise and is at right angles to the surface of the table.

Most vise jaws rise slightly from their seat when tightened up. After tightening up the vise, tap it down with a hammer until it feels solid. If the vise jaws are worn very badly and cannot be relied on, which is usually the case, find the amount of error in your roughing, that is how much it is from being square, then set the surface you have tested by the surface gauge and allow the same amount to be taken off the high side; by using a pair of feelers you can get within two or three thousandths.

If the job projects far enough past the end of the vise, test it with a square from the table. If the vise jaws are in bad shape it may be necessary to put in

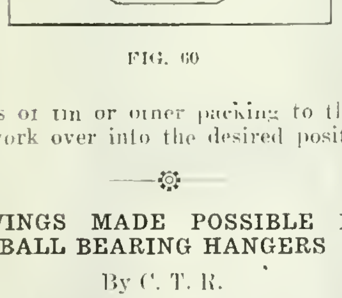

FIG. 60

pieces of tin or other packing to throw the work over into the desired position.

SAVINGS MADE POSSIBLE BY BALL BEARING HANGERS

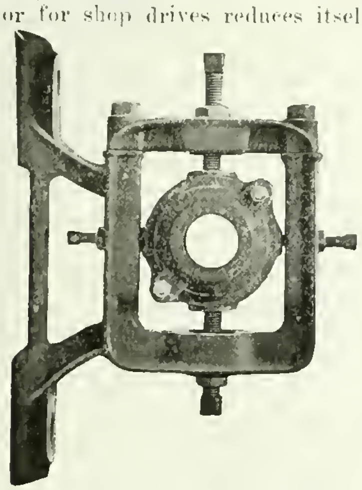
By C. T. R.

EXHAUSTIVE tests in manufacturing plants have demonstrated that transmission losses due to friction of plain bearings amount to from 20 to 40 per cent. of the total power used in the plant. The purpose of this article is to show how the major portion of this loss can be eliminated by the use of self-aligning ball bearings.

Shafts in cast iron, babbitt or bronze bearings become "set" if the shafting is idle for any length of time. The oil is pressed out of these bearings, and it is extremely difficult to start the shaft from rest. Again, when the bearings are operating at normal speed, rubbing friction is constantly consuming power at a sacrifice of efficiency. Self-aligning ball bearings are designed to eliminate all these difficulties.

In self-aligning ball bearings the starting friction is no greater than the running friction. This is a very important fact, for, as it is not necessary to provide for heavier starting loads, a much smaller motor may be used. Again, the rolling friction is practically uniform from rest up to very high speed. On this account they start with a minimum effort, and operate at all times with the highest possible efficiency.

When hangers are equipped with self-aligning ball bearings, the selection of a motor for shop drives reduces itself to

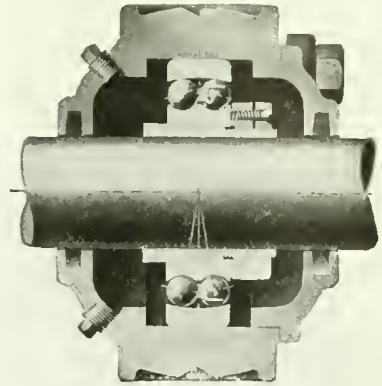


BALL-BEARING POST HANGER.

the problem of providing for normal machine power consumption only, without the necessity of providing for the heavy overload capacity usually required to "start up." For example: if machines in the shop normally require 250 horse-power to drive, and an additional 50 horse-power is consumed by the line shaft in distributing this power, a saving of 50 per cent. of the power required for the line shaft will reduce the total power required by 25 horse-power, i.e., 10 per cent. of the total. With a motor costing approximately $9 per horse power, there will be an initial saving of approximately $225 in the motor cost.

So far, we have considered only the saving in power and the consequent lower first cost of the driving motor. In addition to the saving in power, which alone is a sufficient item, there is also a considerable saving in lubricant. It is necessary to lubricate double row, self-aligning ball bearings only three or four times a year. The lubricant supplied to each bearing at such times is considerably less than is generally sup-

BALL-BEARING PILLOW BLOCK.

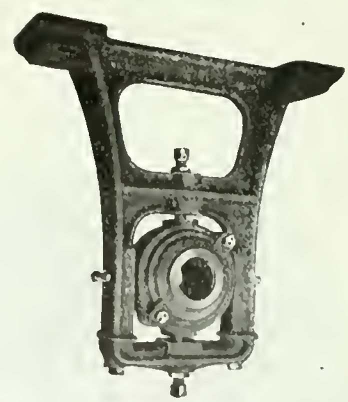


SECTIONAL VIEW, BEARING IN HOUSING.

plied a babbitt bearing several times a month.

This economy in lubrication results from the fact that the liberal lubricant chamber around the bearing is sealed on both sides to insure the retention of the lubricant, as well as to protect the bearings from intrusion of shop dust, grit, etc. The seal is such that the lubricant cannot leak out or creep along the shaft to the pulleys and belts, a feature which preserves the efficiency of the belts and eliminates the uncleanliness and annoyance of oil.

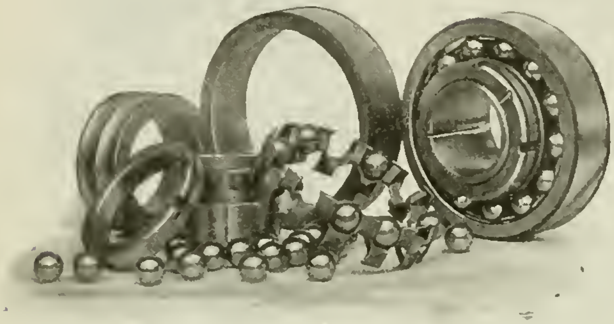
In plants where the transmission is exposed to dust, moisture and grit, self-aligning ball bearings will give the best of service. The dust-proof housing is oil tight, excludes foreign matter and



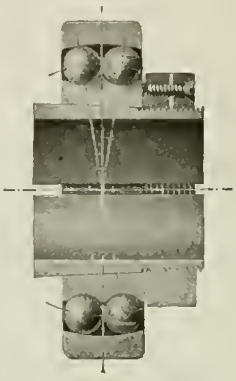
BALL-BEARING DROP HANGER.

holds the lubricant. Cement mills, foundries, woodworking shops and machine shops are some of the places where these bearings can be used to good advantage. Most shafting in plain babbitt bearings is run at speeds from 100 to 400 r.p.m., and if run at higher speeds, it is necessary to lubricate the bearings frequently to avoid hot boxes.*

Self-aligning ball bearings may safely be run at double or triple this speed, the size of the pulleys being cut down so that the rim speed is the same as formerly. A considerable saving in the cost of pulleys can thus be effected; or, when operating at increased shaft speed, by keeping the main line pulleys close to their former diameter (thereby increasing the rim speed), narrower and lighter belts can be used. Working along these lines it is possible to effect savings which will equal the difference in cost between self-aligning ball bearing hangers and plain bearing hangers.



ADAPTER BEARING, DISASSEMBLED AND ASSEMBLED.



SECTIONAL VIEW, ADAPTER BEARING.

Thus, it is possible to secure the highly efficient ball bearing equipment at the same initial cost as the plain bearing equipment.

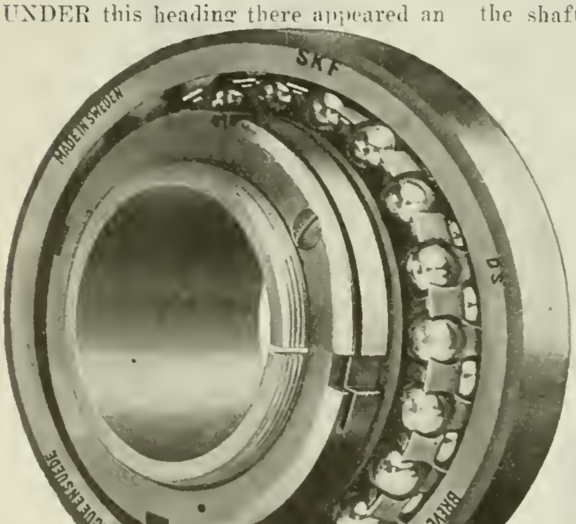
Instances are frequently encountered where a manufacturer is using all his available power and is even operating his engines and boilers or motors at a heavy overload. He constantly faces a complete breakdown of his plant. In order to add more machinery it will be necessary for him to invest considerable money in an extension of his power-generating equipment. However, by using self-aligning ball bearings this would be unnecessary in many cases, while in others, the additional requirement would be on a much reduced scale.

We are indebted to the S. K. F. Ball Bearing Co., Toronto, for the accompanying illustrations.

LINE SHAFT TROUBLES

By H. Westwood.

UNDER this heading there appeared an article in a January issue of your publication. It just serves to remind me of an engineer in a neighboring works to where I was operating an electric plant. The day came when my neighbor engineer had to put a new drive belt on the engine, which was a 20 in. x 36 in. with a 14-ft. fly-wheel.



ADAPTER BEARING, DEFLECTED VIEW.

The old belt was taken off on Sunday morning and the new one put on. Monday morning arrived and found the would-be artist at the throttle. When the engine began to turn over, the belt did not run in the centre of the pulley, but far enough over to the right side to rub the wooden partition that had been placed there to prevent anyone falling into the wheel pit.

"Well, she will have to go till Sunday," was the explanation from George, "there is not enough time at night to undo the splice and re-splice it." Each day that week found the belt rubbing the partition harder until it had nearly worn it through, and as each day arrived, George had a new idea as to what might be the trouble.

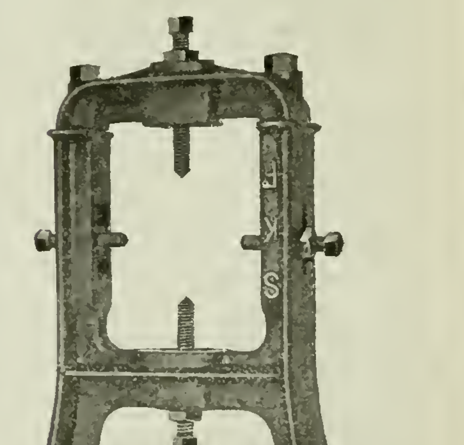
Blaming the Line Shaft

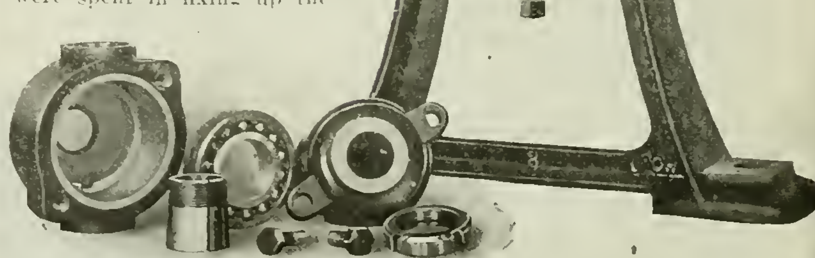
One thing he was sure of, and that was the drive shaft, which was about 150 feet long, was out of line. Next Sunday arrived and with it a gang of men to line the shaft. Some understood what to do and some didn't; however, the shaft was lined and Sunday night found a tired lot of men and the shaft $4\frac{1}{2}$ inches farther from the engine line on the extreme end. Monday morning came and the engine was started up, but, alas, no improvement in conditions of the belt running in the centre, and to make matters worse, several boxes burned out on the line shaft. A couple of nights that week were spent in fixing up the boxes all along the line shaft.

The following Sunday an attempt was made to jack the engine around on the bed, but did not meet with the desired success. The belt by this time had stretched considerably, and some time during Tuesday morning of the third week it took a notion to flop over and run with its back on the driven pulley. To the surprise of George, when he came to the shop he saw the belt running as nice as could be, right in the centre of the pulley, and with all haste he entered the engine room to ascertain the change, and found it.

"Well, I'll just take it off next Sunday and tighten it up and it will be all right!" But George never had the chance, for the following Thursday the place was burned down.

UP TO the present there has not been sufficient systematic research work done to enable the universal adoption of standard methods of impact testing. The two forms most generally used are the Charpy and the Izod. Both methods employ a small notched specimen, which is tested to destruction. The Izol test specimen is required to be of standard dimensions, i.e., 10 mm. square, and must have a sharp V notch 2 mm. deep, carefully machined at an angle of 45 deg. The fineness to which the V notch is cut influences to an important extent the result of the test. If the bottom of the notch is even slightly round, the specimen will yield high results. From this it is obvious, in the designing of practical parts, that sharp corners should be avoided, as they induce the concentration of stresses in that particular portion of the object. The application of a sudden shock causes a crack to commence at the base of the notch, and further fracture is opposed in proportion to the resistance of deformation of the material around the notch.





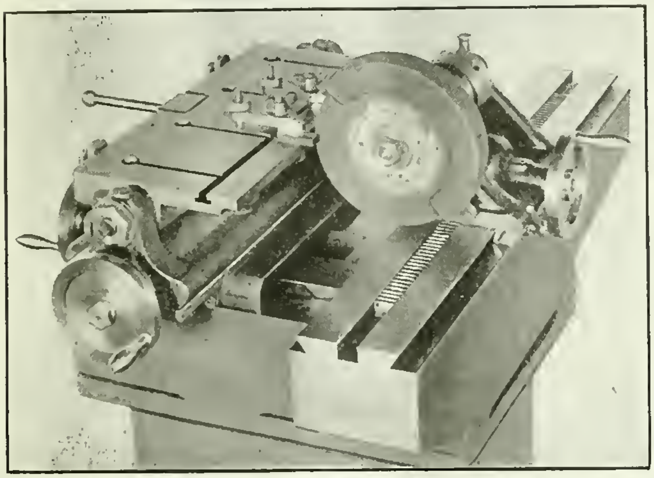
HANGER AND BOX, SHOWING BOX DISASSEMBLED.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

UNIVERSAL GAUGE GRINDER

As a result of industrial developments during the last two years, the making of gauges has assumed considerably increased importance, with corresponding interest in machines used therefor. The machine shown herewith has been designed for manufacturing either snap or master gauges from $4\frac{1}{2}$ in. in depth to $21\frac{1}{2}$ in. in length regardless of steps, but actual use has shown that they can be used for grinding edges on all kinds of special work, while by using inexpensive accessory fixtures, such as tee blocks, etc., their scope of work is largely increased.



UNIVERSAL GAUGE GRINDER.

The detail design is such that the machine is always ready for work, the flat table with special strap clamps and tee slots reducing the time of setting up to passing over pulley has been overcome by using a floating drive on spindle, the pulley being carried independently on a rear spindle bearing and flexibly connected to a driving sleeve fastened on the spindle.

The spindle is of hardened and ground steel carried in high speed bronze bearings lubricated by centrifugal force from a reservoir in each end, felt oil retainers being provided to prevent leakage. The spindle head has a traverse movement of $17\frac{1}{2}$ in., which can be combined with the $4\frac{1}{4}$ in., traverse feed of the table. The end of the spindle takes a wheel up to 6 in. x $\frac{3}{4}$ in. x $\frac{1}{2}$ in. hole.

Crossfeed is operated by means of hand lever and rack and pinion movement, giving a quick movement for removing excessive stock. Combined with this is an additional movement by fine pitch screw and handwheel for extreme accuracy and fine finish. Telescopic dust guards are fitted to the carriage slides.

The table is of ample size to take all classes of snap or master gauges, and has a perfectly flat working surface on which the work is fastened. Permanent strap clamps and suitable tee slots facilitate the fastening of the work. Duplication of the work is accomplished by a setting gauge which has an included tilt of 10 deg., up and down enabling the grinding of thick or thin gauges, while still keeping the centre of the work on a line with the centre of the wheel. The table traverse can be controlled to .0005 in.

The arrangement of the machine enables the operator to sit down when manipulating same and watch the work to best of advantage.

The builders of this machine are the Steel Products Engineering Co., Springfield, O., who supply it complete with self-oiling countershaft and 6 in. emery wheel. The size of table is $6\frac{3}{4}$ in. x 13 in. feed of table 3 in., table traverse $4\frac{1}{4}$ in., spindle head traverse, $17\frac{1}{2}$ in., floor space 21 $\frac{1}{2}$ in., x 30 in.

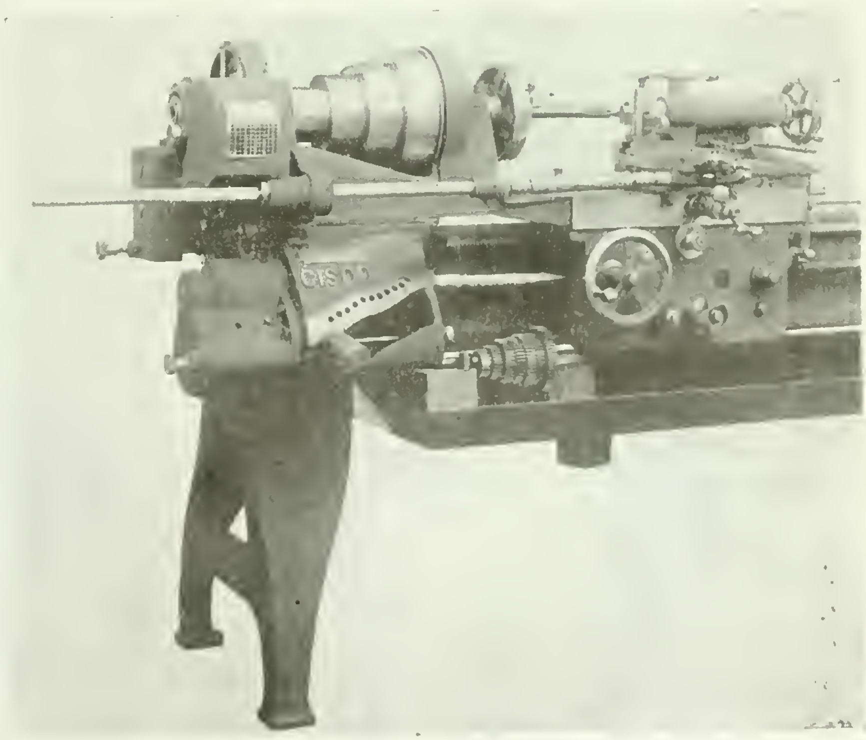
RELIEVING ATTACHMENT FOR ENGINE LATHE

THE accompanying cut shows a relieving attachment which has been designed by the Cincinatti Iron & Steel Co., Cincinatti, O., installed on a lathe of their manufacture. Every effort has been made to provide a satisfactory device combining simplicity of design with efficiency of operation.

The attachment is driven by a gear on the outer end of the lathe spindle, which replaces the spindle bush, and does not necessitate any change in the spindle itself. This gear meshes with an idler, which in turn drives a set of change gears on a swinging quadrant mounted on the drive box. This box is bolted to the front of the headstock, and contains the gears which drive the sliding shaft.

A supporting bracket for the sliding shaft is mounted on the adjacent side of the carriage, thus permitting a wide latitude in the position of the carriage when relieving. A telescopic shaft with two universal joints connects the end of the sliding shaft with the cam shaft, giving correct compensation for slide and swivel adjustments. The swivel can be turned to an angle of 30 deg., and all bottom slide and top slide adjustments when connected with the relieving attachment are made exactly as with a regular lathe. The taper attachment can also be used in conjunction with the relieving attachment.

One single and one double impulse cam are provided with each attachment, the cam shaft, which runs in bronze bearings, being easily removed for changing cams. The cams operate against



RELIEVING ATTACHMENT FOR ENGINE LATHE.

a hardened steel roller held in a hardened steel slide, which is connected to the top slide screw, and has a spring rod with two adjusting nuts for governing the amount of throw or relief; or, it can be set to hold the slide and roller away from the cam when the compound rest is required for regular work.

Six change gears are provided, which give thirteen numbers of flutes from 1 to 8 inclusive, and 10, 12, 14, 16 and 20.

SHRAPNEL SOCKET MACHINE

THE machining of brass sockets for shrapnel offered good opportunity for the application of single purpose machines, and the facing and threading machine illustrated herewith is one which has proved capable of maintaining an average production of slightly over 700 pieces per 10 hour day. The outside operation, as it is termed, is performed after the inside work is done, it being possible to place the work and remove it without stopping the spindle. The tool, which is of the formed type is then fed forward by the lever, cutting, facing and forming the socket by the one movement, which leaves the work ready for threading.

The chaser bracket which swings backward when not in use, is now dropped into place and is traveled across the work by a threaded drum. This machine is built by the Canadian Chadwick Metal Co., Hamilton, Ont.

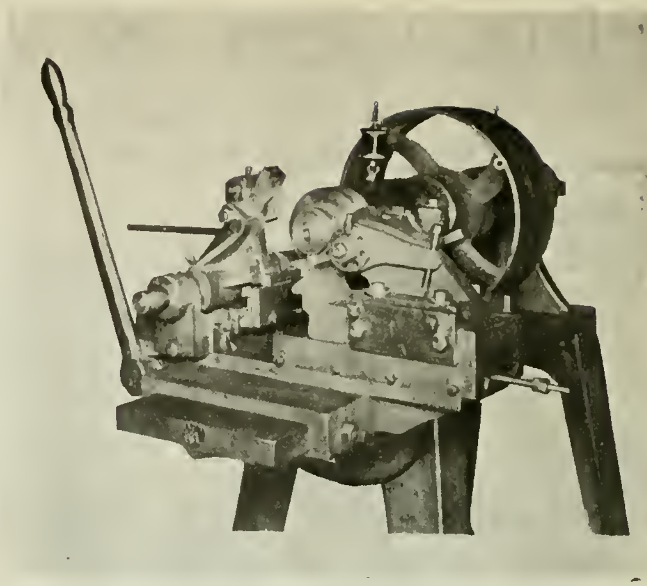
20 IN. CRANK SHRAPNEL

PRESENT day demands have been carefully studied by the builders of the 20 in. crank shaper shown in the accompanying engraving, ample rigidity, power, and convenience of operation having been combined with simplicity, reliability and accuracy of construction.

The frame and base are cast in one piece, and an oil pan inside the base catches all drip from the bearings. The hub carrying the bull gear is cast solid with the frame, and is liberally proportioned. Both the crank pin and the crank pin block are hardened and ground, the block being bushed with a cast iron sleeve for crank pin bearing.

The ram has a bearing in the frame of $11\frac{1}{4}$ in. x 34 in., and is amply braced to carry heavy cuts. It can be set in any position while in motion or at rest, an index showing the length of stroke.

Cross feed mechanism is operated entirely at end of cross rail, in all its adjustments. The feed takes place on reverse stroke only, the amount being indicated on a dial. A ball lever on top of feed gear casing starts, stops, or reverses the feed while in motion. The tool head swivel is securely bound to the head of ram by a single screw, and micrometer dial is provided for indicating feed in thousandths.

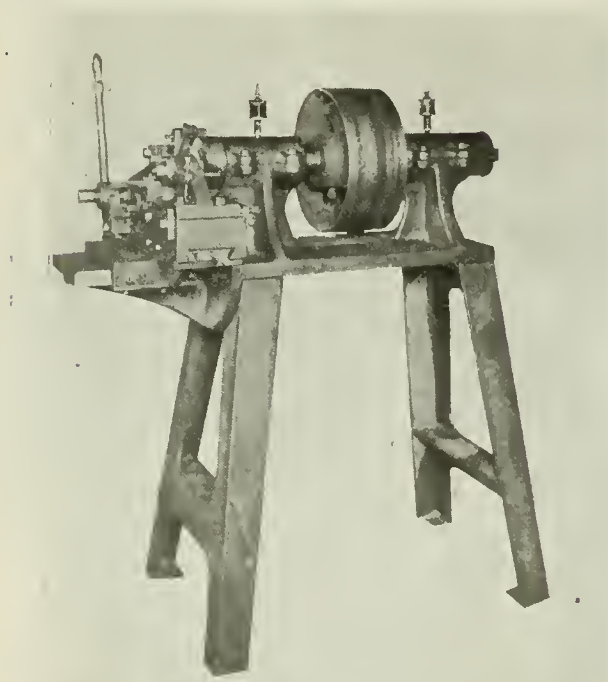


FACING AND THREADING MACHINE FOR 18-PDR SHRAPNEL BRASS SOCKETS.

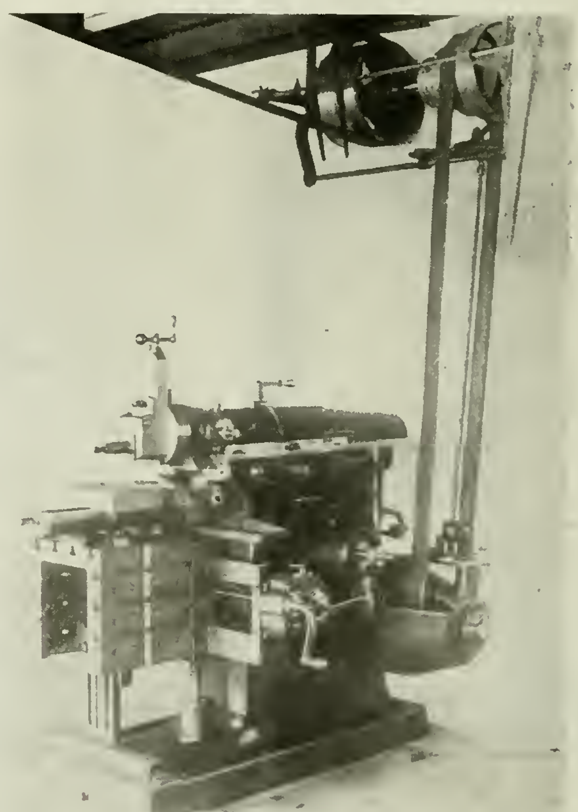
An outboard bearing which acts as a belt guard is provided for the shaft of the four step driving cone. An expanding friction clutch drive of large diameter, which engages with the cone, is operated by a long horizontal lever at side of frame. Eight speeds are obtainable through the medium of back gearing.

An adjustable bottom support under the table slides on a channel shaped track which protects it from chips and dirt. A graduated base on the vise is held down by four bolts and acts as a clamp which holds the vise solid to table.

The actual stroke is $20\frac{3}{4}$ in.; horizon-



FACING AND THREADING MACHINE FOR 18-PDR. SHRAPNEL BRASS SOCKETS.



20-INCH CRANK SHAPER SHOWING ALSO BELT SHIFTING MECHANISM.

tal travel of table $24\frac{1}{2}$ in.; vertical ditto 15 in.; top of table, 16 in. x 20 in.; power cross feed, .008 in. to .200 in.; ram. strokes per min. 8-115; net weight, 4,100 lbs. The Hendey Machine Co., Torrington, Conn., are the builders of this machine.

CORES, THEIR CONSTITUENTS AND COMPARATIVE COSTS

IN a paper read before the Scottish Branch of the British Foundrymen's Association on January 13, Arthur Naylor read a Paper on "Cores, and their Material Constituent, and Comparative Costs." Mr. Naylor remarked that it is now considered an established practice to separate coremaking from the trade of moulding, and very few foundries are now to be found where there is not a core-making department. This is not only a more economical arrangement but it is an arrangement by which greater efficiency is obtained. The question of materials used in core-making varies to some extent with local conditions. The price charged for carriage of new sand has also an important bearing upon the subject, in determining the proportion of new and old sand to be used.

Oil-Bonded Cores

With inexperienced foundrymen, the question of comparative costs, with regard to ordinary sand cores and oil-bonded cores is a debatable matter. At glance it seems a costly procedure to use oil at say, $8.50 to $10 per 100 lbs. compared with using ordinary sand. However, as a result of actual practice there is no doubt that the use of oil-bonded cores is more economical. For ordinary work, sea sand bonded with linseed oil serves admirably for cores. It is not always advantageous to use oil-bonded cores in every instance, but for work such as steam-chest cores, cylinder-port cores, cores for water-jacketed cylinders, compressors, etc., and in all cases where the extraction of the core after casting presents a difficulty, nothing could be more suitable or more economical than oil-bonded cores.

The amount saved in dressing such castings more than pays for the oil also any extra work involved in the production of the cores. In the majority of cases an oil-bonded core does not take any longer to produce than a similar cor made in ordinary sand; it has also these further advantages, that fewer core irons are required and less venting is necesary than with similar cores in ordinary sand. The question of drying is slightly against the oil-bonded core, but a little experience soon overcomes any difficulty met with in this respect. The temperature of the stove for drying such cores should not exceed 500 deg. Fah. Oil bonded cores are much easier to handle and less liable to break when placing in position, and they may be left any length of time in the mould before casting as they do not absorb moisture.

An example from personal experience was given to show the comparative costs of the two systems of producing cores. That selected was the cores of a water-cooled gas-engine cylinder. At first these cores were produced in the ordinary way by grinding a quantity of loam taken from a used mould; this powder was again dried in the stove and then milled with an equal proportion of new sand, and a liberal proportion of horse-dung and clay-water. The production of these cores, including the necessary core irons, took from four to five days, and after the castings were made it took $1\frac{1}{2}$ to 2 days to remove the cores. When the system of oil-bonded cores was adopted the cores were extracted from the castings in 15 minutes. The cost of each system is shown in the following tables:

Ordinary Sand Cores

Sand and mixing	00.75
Core Irons	3.75
Making Cores	11.00
Dressing and blackwashing cores	2.50
Dressing castings	5.00
Total	$23.00

Oil Bonded Cores

Sand and mixing	.75
2 gallons oil at 4s. per gallon	2.00
Making cores	7.50
Dressing and blackwashing cores	2.50
Dressing casting	1.75
Total	$14.50

The core irons for oil-bonded cores, where these are necessary, may be wrought iron, and re-used from time to time; the ends of these irons should be arranged to project into the print of the core, and when this precaution is observed the irons can be easily removed from the casting. Any vertical recesses left by the removal of loose pieces in the core-box should be filled with dry or wet parting sand, and removed after the core is dried. Should these recesses be in a horizontal position the spaces must be formed by rubbing down a small piece of dried core to the shape of the recess; this should be covered with paper and rammed up with the core, the paper forming a parting substance to facilitate the withdrawal of the small core after the main core has been dried.

If any part of the main core is to come into contact with the plate for supporting the core while drying, the part coming in contact should be separated by a piece of paper, otherwise it may adhere to the plate. Should any sharp edges be exposed to the heat they are liable to burn. This may be avoided by spreading a litle oil from an ordinary oil-can over the exposed part. Oil-bonded cores contract about one-eighth of an inch per foot, and provision for this has to be made in the core-box.

Scabbing is practically an unknown factor with oil-bonded cores, provided a clean open silica sand is used. The boxes in which the cores are made should be well oiled to prevent the sand adhering to the sides of the box. We are indebted to the Foundry Trade Journal for the foregoing synopsis of the Paper.

EXPORTING ZINC FROM JAPAN

THE British Vice-Consul at Osaka, Japan, G. White reports that exports of refined zinc from Kobe and Osaka in 1915 amounted to 3,700 tons, valued at £311,000. Prior to the war, Japanese refined zinc had to face severe competition in Japan itself from imports and was unable to pay its way. Everything changed with the outbreak of the war and the refineries, being free from competition were only concerned how most rapidly to increase their output to meet home orders and orders from abroad. The output, which was estimated at 5,000 tons in 1914, amounted to from 16,000 to 18,000 tons in 1915, and is expected to reach 25,000 tons or more in 1916.

From exporting concentrates Japan has come to importing same, and in 1915 supplies were imported from China and Siberia. Attempts were also made to obtain concentrates from Australia. Two companies were responsible for the greater part of the output in 1915, although small concerns between them refined some 2,000 tons of zinc. Hitherto, there has been only one factory using electrolytic methods, but the remarkable difference in price between the purest quality and the lower grades, and the difficulty of producing the former by the "dry" method, has led to the erection of two other electric furnaces, the total output by this method being about 700 tons per month.

CANADIAN FISHERIES INCREASE

THE total value of Canadian fisheries during the last fiscal year, according to the annual report of the Fisheries Department, was slightly less than $36,000,000, an increase of four and a half millions, as compared with the previous year. It is anticipated that if the new arrangements with the War Office for the use of Canadian fish is a success, these figures will be greatly increased in the future.

Of the increased value over three million dollars is attributable to a bigger catch in British Columbia waters. The Rivers Inlet, Skeena River and Naas River districts contributed over two millions. The increase due to an increased pack of salmon and higher prices.

A substantial increase of $1,436,000 is recorded in Nova Scotia fisheries. The value of New Brunswick catch fell off $300,000. Prince Edward Island by $300,000 and Manitoba by $106,497.

The value of Quebec fisheries increased by $152,421. Salmon with a production of upwards of eleven million dollars, continues to hold first place as the most valuable of Canadian fish.

CANADIAN STEEL INDUSTRY OUTLOOK

THE uncertainty of the meantime international situation, as regards the entrance of the United States into the war arena, is having no material effect on the production activities of steel mills, whether in Canada or the United States. Rather the reverse, we might say, and, taken in conjunction with the high prices now ruling for steel products, the every-day more near approach to relief from transportation disabilities, and the very comprehensive and extensive shipbuilding programme—wood and steel, now initiated in Canada, there is ground for little else than well-found optimism as regards the metal-working plant outlook—munitions and otherwise. Not only is progress being made in the development of the shipbuilding and marine engineering plans as outlined here a week ago, but many of the disabilities under which our steel and other engineering industries have been laboring are being gradually removed. As an evidence of this in but one direction, the Steel Company of Canada, Hamilton, Ont., have blown in their No. 2 furnace which has been standing idle for some time, and are now operating their No. 1 furnace at full blast.

Production of steel during February was much curtailed, and while that for the present month may possibly fall short of expectations, there is nevertheless considerable evidence available to indicate that net earnings of our various producers for 1917 will equal, if not surpass, those of 1916. Not the least satisfactory feature of the annual statements of our steel corporations, so far available, is the conservative distribution of the accrued profits from the past year's operations or more. The motive prompting the action indicated may be one or other of not a few that readily occur to students of the industrial situation in Canada, present and prospective. However, in view of the fact that steel shipbuilding is about to assume large proportions within our borders, and is destined to assume a permanent value hitherto unapproached, it may readily be assumed that the retention of large surplus earnings belongs to a policy which will in the near future find practical expression in the installation of plate mills—ship and boiler plate, by more than one of our principal steel corporations. Lack of steel for ship construction is probably more acute than the lack of shipyards on our lake and ocean shores. It is therefore more contributory to the non-carrying out of the shipbuilding programme now being launched, with that degree of dispatch so much desired, because so clearly urgent.

CANADA'S DIRECTOR OF SHIPBUILDING

IN THE appointment of J. W. Norcross, vice-president and general manager of the Canada Steamship Lines, as director of shipbuilding in Canada, we find evidence of an effort to appoint for the management of public affairs, men who have shown through their success in business and industry their practical ability and executive capacity to handle big projects—to do things and to get things done. Mr. Norcross, co-operating with the Imperial Munitions Board, is to organize the shipbuilding facilities of Canada in the interests of the British mercantile marine. A better man could not perhaps have been selected. He knows the sailing and construction of a vessel, and has proven that he can plan, finance and successfully carry out large undertakings. A few years ago a lake captain, to-day the recognized genius of the Canada Steamship Lines and a prominent authority upon water transportation in Canada, Mr. Norcross is the type of executive required in the handling of our national business generally. It is to be hoped that the example which the British authorities, through the Imperial Munitions Board, have shown in picking the man that the position demanded and setting aside all other considerations will be followed by the powers that be at Ottawa in other directions. There are many big business men in Canada who to-day should be filling Dominion portfolios, not because of their political influence or public popularity, but because the country's affairs require their services for efficient administration.

TRAINING SCHOOLS FOR APPRENTICES.

VERY few of our firms are in a position to operate individual training schools for apprentices, and the feasability of co-operation among employers is suggested thus by a writer in a contemporary: "Why not get together within the industry and organize what will be frankly trade schools, owned and operated by the manufacturers through the medium of stock companies where boys shall be offered opportunities that they cannot afford to pass by?" This remark is quoted without any disparagement of the work being done in technical schools; attendance at such institutions does not always mean that the student will join the ranks of skilled mechanics—frequently he is induced to leave and enter the employ of some firm which fails to realize that it is to his own and the industry's ultimate loss.

The equipment and instruction given in a jointly owned school could be of a varied yet thorough nature which while in line with the general requirements of the student's employers would insure his ability to tackle any work not absolutely specialized.

Out of the large number of present operators, drawn from many sources, quite a few bright individuals will certainly be available for and ready to take advantage of all trade school instruction offering, all of whom might well form the nucleus of a later addition to the ranks of trained machinists, an asset of considerable value to the trade, employers, and the nation.

INDUSTRIAL NOTABILITIES

CHARLES FREDERICK WHEATON, general manager, the Dodge Manufacturing Co., Ltd.—a $1,500,000 corporation producing power transmission machinery, elevating and conveying machinery, Osler and Pelham streets, Toronto, was born at Brantford, Ont., October 17, 1859, son of James Franklin and Margaret Wheaton. He was educated in Public Schools, Toronto, and started his business career as office boy with Henry L. Smythe, Montreal in 1870. From 1872 until 1877 he was employed by Russell & McLean, wholesale milliners, Montreal. From 1878 until 1883, he was associated with Thomas May & Co. and Paterson Bros., Toronto, in the latter year becoming bookkeeper to Samuel May. Two years later, this gentleman

CHARLES FREDERICK WHEATON.

purchased the patents covering the Dodge split wood pulley, Mr. Wheaton being placed in charge of the new department. In due course, the Dodge Manufacturing Co. was incorporated, developing under Mr. Wheaton's management until its output now reaches a value of $1,000,000 per annum.

Mr. Wheaton married Ida Gertrude Holmes, daughter of Robert Holmes, Toronto, their family consisting of one son and three daughters. His Clubs are the National, Albany, R.C.Y.C., and Canada Bowling, Toronto; and Engineers, Montreal. He served with F Company, Queen's Own Rifles from 1880 to 1883. His recreations are motoring, bowling and billiards. In politics he is Conservative and, in religion Methodist. The family residence is 122 Bedford Road, Toronto, Ont.

The General Market Condition and Tendency

THE most important feature in industrial circles of recent date is the contemplated development of the shipbuilding industry. While plans have not yet been matured, it is understood that all the available shipbuilding capacity of this country will be utilized for the production of ships for the British Government. The threatened strike of railway employees in the United States has happily been averted, but there was considerable suspense for a few days, as it would have seriously affected business here. Prices of steel products continue to climb and the end of the upward movement is not yet in sight. Iron and steel bars and shapes have advanced this week approximately $6 a ton, while higher prices on rivets, bolts and nuts, plates, tubes, black and galvanized sheets, are looked for in the near future. The situation in the steel trade is steadily improving and production is increasing. Hamilton foundry iron is again on the market at $43 a ton, a new high level and one that will doubtless be surpassed. The pig-iron market is strong and active, while the situation shows some improvement in regard to more liberal supplies of coke. Prices of copper and other non-ferrous metals are unchanged from last week's level, but the market has a strong undertone and indications point to a continuance of high prices. The machine tool market, although comparatively quiet, is more active than earlier in the year. The demand consists largely for small lots or on single tools for munitions plants. The scrap metal market is firm and prices have been well maintained during the week.

Montreal, Que., March 19, 1917.—Several circumstances have combined to unsettle the general tone of the industrial situation. The threatened railroad strike was a disturbing element, but this danger has apparently been removed for the time being at least. The changed political conditions recently evolved in Russia will undoubtedly exert an indirect effect upon the industrial outlook there. Developments point to an early change in the attitude of the States, as their "watchful waiting" policy has apparently reached the limit. The return of cold weather has delayed the breaking up of the ice on the rivers and lakes, and the opening of navigation will likely be somewhat later than usual.

Pig Iron

The market has again been featured with a further advance in pig iron, a $3 increase being recorded at many centres. Pittsburg is now quoting $33.95 for basic, an advance on the week of $3 per ton; Bessemer pig, on a $1 rise, being quoted at $37.95 per ton. Canadian quotations are still withdrawn.

Steel

Added to the pressure that has been so marked in all lines of manufacturing activity, steel industry may be confronted at any moment by the long delayed action of the United States Government in entering as a combatant in the now almost world-wide conflict in Europe and on the High Seas. The result of an actual war declaration is largely problematical at present, but what appears as a certainty would be the increased impetus given steel manufacture. This will, no doubt, mean much to the Canadian steel industry, as producers here may be compelled to increase their facilities to meet the needs of manufacturers who have been dependent on American steel in the past. Producers would likely be placed in a curious position owing to their future bookings, which in event of war might divert much of this tonnage into other channels. Developments in steel shipbuilding are making enormous strides, and as soon as plates are available the activity in this industry promises to equal, if not surpass, that of the present shell business. The nature of the undertaking, however, will confine it more to marine highways, the large rivers and seaports being the chief benefactors. Further advances in basic pig will probably affect the early future of steel prices, as many commodities are already showing a trend to higher levels. A feature of the situation is the reluctance of American roads to permit cars to enter Canada, due to the resultant delay in having the same returned for further use. Producers of wire rods are able to use almost their entire output, but what surplus is available for sale is bringing the high price of $85 per ton, this being an advance of $5 per ton. The recent advance on wire product is well maintained and the demand continues, mills being booked well in advance. The strong position of plates has resulted in additional advances, and ship requirements are so great that higher levels are not unlikely. An advance of $5 per ton has become effective in sheets, the Pittsburg price on tin mill black being now $5.25 per hundred.

Structural and boiler rivets have taken a jump of $10 per ton, the respective quotations being $4.75 and $4.85 per hundred. The filled-up condition of wrought iron and boiler tube mills has prevented the heavy booking of additional business, and a stronger tone has developed. Local steel merchants are contemplating a revision of price lists, and intimate that the next few days will see some substantial changes in an upward direction. This has become necessary through the continual advance across the line, coupled with other contingencies.

Metals

The general situation has been somewhat disturbed during the past week by the threatened tie up of American railroads, but this nervousness has been partly removed by latest reports which indicate that this crisis will not develop at this time. For several days, embargoes were general at many points, owing to the action of railroads clearing themselves of perishable and urgent freight. With the exception of antimony, which is stronger, the metal situation shows an easier undertone. Copper is quiet and inactive. Tin is lower but uncertain. Consumers interest in spelter is marked by its absence and a weak tendency has developed. Lead is easier in the open market. Antimony is scarce and stronger. Aluminum is unsteady.

Copper.—The market is quiet and the tendency is for lower prices on what business is being transacted. A noticeable feature appears to be the increased available supply of metal for early future delivery. A closer check is to be placed upon export of American copper, the government having issued orders to withhold information regarding the shipment of metal. The London market is firm, but the American situation is apparently easier, New York quoting ½ cent lower on electrolytic. Dealers here report a weaker tone but prices are steady, lake and electrolytic being 43 cents, and castings 40 cents per pound.

Tin.—Owing to the safe arrival of tin and the apparent lessening of risk in transport, the market has taken on an easier tone and the movement is toward lower levels. Cautiousness however, continues to prevail and sharp declines are not anticipated. The threatened railroad strike had the effect of disturbing the situation and spot tin was easier, but with this possibility removed the market has regained its steadiness, although showing a weak undertone. London has become stronger but New York is quoting 53¼ cents, a decline on the week of ¾ cents per pound. With tin developing a weaker tone here, dealers continue to quote 53 cents on a steady market.

Spelter.—The lack of interest on the part of consumers has created a dullness that has reflected itself in lower quotations. The strength of the market is being maintained by the high cost of ore and the difficulty experienced in getting it delivered to the smelters. New York is quoting 10¾ cents, this being a decline of ¼ cent on the week. Local dealers are asking 15 cents on a quiet but firm market.

Lead.—The relief experienced by the improvement in railroad conditions has had the effect of putting lead on an easier basis and spot metal is more plentiful. London and New York continue firm, but independent American producers have reduced quotations to 10 cents; this being a decline on the week of one cent per pound. The local situation has taken on an easier tone, dealers here quoting 12 cents per pound.

Antimony.—The scarcity of spot metal, caused by the non-arrival of metal in transit, has developed a stronger market for prompt delivery, but the activity in futures is very light. New York quotations have advanced one cent on the week but local prices are firm and nominal at 34 cents per pound.

Aluminum.—The present demand is not heavy but the scarcity of metal tends to maintain a strong market; local quotations are firm at 70 cents per pound.

Machine Tools and Supplies

The situation shows a slight improvement over the previous week, but deliveries have been somewhat hampered by the recent railroad disturbance. The feature that dominates the present market is the unsettled condition prevailing across the line and the uncertainty of the early future possibilities. With the prospect of definite action on the part of the American government, much of the available equipment, both new and second hand is being secured, for probable contingencies. With manufacturers operating on a home war basis, the industries here in Canada will be forced to rely more than ever upon their own resources for future requirements.

Scrap

The market for all classes of old materials continues to maintain strength, and higher levels, mark an active situation. The heavy demand for steel scrap and the difficulty of obtaining delivery point to stronger prices, and advances are not improbable. Brass scrap shows a better undertone but local dealers are holding firm on last week's quotations.

Toronto, Ont., March 20.—While the demand for manufactured products is still heavy, other features of the industrial situation are not so satisfactory. The threatened railway strike in the States promised to tie up the traffic and dislocate business generally. Fortunately the trouble has been averted but it has left behind a feeling of unrest. The freight situation is gradually improving, but is not by any means satisfactory and manufacturers are still handicapped by a shortage of materials. Scarcity of labor is also adversely affecting production with no relief in sight. The contemplated development in the ship-building industry is expected to improve the demand for machine tools and the outcome of the proposals is being watched with interest. The scheme is an important one and its effect will be far reaching.

Steel

The situation in the iron and steel trade is steadily improving and the output of the mills is increasing in tonnage. The acute situation on the railways has been relieved to some extent, principally in regard to coal and coke, but conditions are not by any means normal. The decline in production during the first two months of this year has put the mills further behind on deliveries, while the demand for steel is not showing any indication of falling off. The steel market continues very strong and prices are still climbing. The recent advance in prices of steel bars and shapes in the States has been followed by higher prices in this market. Bars and shapes have advanced $6 per ton and are now being quoted as follows. Iron bars, $4.25; steel bars, $4.50, and shapes, $5 per 100 lbs. Higher prices in the near future may be looked for on plates, tubes, structural and boiler rivets, and spikes. The plate situation is the feature of the steel market. The demand is enormous with every indication of it becoming considerably heavier. The consumption of plates for shipbuilding, alone, is and will for a long time, be extremely heavy, while car builders are also taking considerable tonnages. The recent advance of $15 a ton on plates in the U.S. was the sharpest made by the Carnegie Co. in many years. Wrought pipe is very firm at the recent advance and still higher prices are looked for.

About the end of the month there will likely be another advance in black sheets. An advance of $5 a ton on black and blue-annealed sheets, and $3 on galvanized sheets recently went into effect in the States. Freight conditions have improved, and the situation at the mills in regard to supplies of fuel and raw materials is easier. Labor costs, however, are higher and cost of production is, therefore, increasing.

Chicago warehouse prices on bars, plates and shapes have advanced and are now quoted as follows out of jobbers stocks: Bars, 4c.; plates, 5.50c.; and shapes, 4.25c. The steel market in the U.S. is very strong and prices continue to go up with further advances looked for on all steel products. The recent advances have had the effect of stimulating business, the demand for steel products being very heavy both export and domestic.

Pig Iron

The Steel Company of Canada have recently blown in their No. 2 furnace at

Hamilton and have issued a price of $43 a ton on foundry iron. Supplies of coke are coming forward in better volume and the situation has consequently improved. The pig iron market is very strong and higher prices are likely at no distant date. There has been a general advance on practically all grades of pig iron in the States and the market there is unusually active. The demand for pig iron is ahead of the supply and a scarcity has developed. The coke situation has improved and prices are easier.

Scrap

The scrap market has been active during the week and prices have been maintained at the levels quoted last week. There has been fairly heavy buying of heavy melting steel and low phosphorus scrap. Cast iron scrap is also in good demand owing to the shortage of pig iron. Prices of copper and brass scrap are firm, but unchanged.

Machine Tools

The machine tool market is a little more active than earlier in the year. The demand continues to be principally for small lots or for single tools for munitions plants. This class of business, however, has fallen off considerably, although there is still fair demand for machine tools for munitions plants. Machine tool builders and dealers are showing a lively interest in the proposed development in the shipbuilding industry. It is expected that a good demand for shipyard machinery will spring up concurrently with existing shop extensions and improvements, and possibly also for new plants.

Supplies

An active demand for machine shop supplies prevails and prices are holding firm on practically all lines. Manufacturers of lubricating oils and cutting compounds announce that a revision of prices is under consideration and will be issued in a few days. It is likely that the new prices will show an advance over the present levels.

Metals

There are no new features of importance to note in the metal markets this week. With the International situation still unsettled there is a tendency on the part of consumers to await developments, consequently business is quiet. There is, however, a strong undertone to the markets due to the expectation of the United States taking an active part in the war. Prices are holding firm and are at the same level as last week for all metals. Business locally continues very good.

Copper.—The market is quiet and quotations easier, but unchanged. There is, however, a strong undertone to the market on account of the continued enormous consumption which shows no sign of diminishing. The demand for copper continues to exceed the supply and will continue to do so for the duration of the war. Lake and electrolytic copper is quoted at 40c., and castings at 39c. per pound.

Tin.—The market is dull and easier, although quotations are unchanged. A new development in the market is the possibility of a tax being imposed by the British Government on the export of tin to the U.S. As shipments of tin have in the past been sufficient for requirements in the States it is doubtful if the proposed tax will be levied with the intention of conserving supplies in England. Local quotations unchanged at 56c per pound.

Spelter.—The demand for spelter continues light with little prospect of any improvement in the meantime. The market is dull and quotations unchanged at 14c. per pound.

Lead.—There is no change in the situation. The market, although a shade easier has a strong undertone, the easier tendency being due to lack of demand. Local quotations are unchanged at 12½c. per pound.

Antimony.—There is still a scarcity of antimony particularly on large sized lots, which are practically unobtainable. The market is strong and quotations firm at 35c. per pound.

Aluminum.—The market is strong but quiet, and quotations are unchanged at 68c. per pound.

Sydney, N.S., March 16.—The coal mines throughout the province are working at full pressure, and production has been favored by the open weather that has characterized the winter in Nova Scotia. The reduction in the coal outputs seems temporarily stayed, owing to the restrictions on recruiting, but it is not likely that any increase over present outputs can be obtained. When the spring planting season starts there will be the usual exodus to the farms and fisheries, and there are no sources from which new workers can be obtained. It is to be hoped the National Service directors will not again allow the Maritime Provinces to be drained of laborers by the Western harvest excursions, as was the case last summer, when some 1,800 men, chiefly from the coal mines in Cape Breton and the munitions works at New Glasgow, left for the West.

One or two small ventures in coal mining are reported. The Greenwood Mine, in the Thorburn district, Pictou County, is producing some 200 tons daily from a small rise area of coal left from the workings of a previous operator, and is finding a ready sale for all the coal that can be produced. It is probable that the Broughton Mine, of the Cape Breton Coal, Iron & Railway Co., near Glace Bay, will be shortly reopened. This mine, owned by English capital, has been lying dormant for several years, and it is stated that a lease of the properties has been given to local parties, who expect shortly to commence unwatering the mine. There is also a possibility of some work being done at the Port Hood colliery, in Inverness County, which was flooded from the sea some years ago. It is not the intention to unwater the flooded section, but to work some rise coal, if this is found available in sufficient quantity. It is also reported that the Mabou colliery, in the same district, and also flooded by the sea, may be reopened.

Considerable interest is felt in Sydney in the newspaper reports of the intention of the British Government to encourage shipbuilding in Canada, through the medium of the Imperial Munitions Board. The people of Sydney have long been fully convinced of the excellent facilities which Sydney offers for a shipbuilding industry, among which may be mentioned the proximity of the large steel works of Cape Breton Island, the nearness of the coal mines, and the capacious and safe harbor which Sydney possesses. Strong efforts are to be made to secure the most favorable consideration of Sydney as a location.

CANADIAN TRADE INCREASES IN VOLUME

THE volume of Canadian trade maintains a steady tendency, according to a statement just issued by the Minister of Customs. For the eleven months of the present fiscal year ending February 28 last, the exports of Canadian products and manufacturers reached the large total value of $1,028,960,000. For the same period merchandise entered for Canadian consumption totalled $742,-995,000, an excess of exports over imports of $285,065,000. These figures are exclusive of the imports and exports of coin and bullion and the export of foreign merchandise. The total merchandise for domestic consumption and export reached $1,771,955,000 for the eleven months of the present fiscal year, compared with $1,098,945,000 for the corresponding eleven months of the fiscal year 1916.

For the month of February last Canada's trade was $136,254,000, against $109,586,000 for February, 1916, these figures being exclusive of foreign merchandise passing through Canada and the exports and imports of coin and bullion. Of the exports for February last, manufactures led the way with $39,504,-000; agriculture, $11,449,000; animals and their products, $7,652,000; minerals, $5,074,000; fisheries, $1,655,000; products of the forest, $2,459,000.

Increase of Exports.

With the exception of agriculture, the exports of which have fallen off to the value of $2,000,000 from February, 1916, these exports show a large increase over the corresponding month of last year, when the total exports were $57,931,000.

For the eleven months of the present fiscal year the largest increase is shown in the export of manufactured articles, being $408,160,000 for the eleven months ending February, 1917, as against $195,-021,000 for the corresponding eleven months of 1916. The exports of agricultural products were $351,451,000, against $231,808,000; animals and their products, $112,985,000, against $94,255,000; products of the forest, $52,292,000, against $48,023,000; minerals, $75,636,000, against $58,585,000; fisheries, $22,515,-000, against $20,323,000.

Imports for February

The figures respecting imports for February show a large increase in the value of dutiable goods and free goods.

Dutiable goods imported during February last totalled $36,490,000, as against $29,097,000 for February, 1916. Free goods also show a substantial increase, being $31,540,000 for February last, against $22,557,000 for February, 1916.

For the eleven months ending February last the total imports of dutiable goods were $407,136,000, against $254,551,000 for the corresponding period of 1916. Free goods were $335,585,000, as against $191,196,000.

The duty collected for the eleven months ended February last was $130,550,000, as against $91,757,000 for the corresponding period of 1916.

FINANCING SALES ABROAD BY DRAFTS

IN its issue of February, the *Foreign Trade Bulletin* of the American Express Co. sets forth the following instructions for financing sales abroad by drafts. Extending credit to foreign buyers does not involve a tie-up of the manufacturer's capital, when shipments are financed by drafts. No manufacturer of good standing need wait for his money on such sale. His draft against his foreign customer, drawn payable to his own order and endorsed with his signature, can be discounted, thus providing the manufacturer with the funds necessary for his own current business. Discounting charges are paid usually by the foreign buyer, because the buyer receives time accommodation for which he is willing to pay. These charges may or may not be apparent on the face of the draft itself, although the net result is the same in that the drawee pays costs. For instance, most dollar drafts against Far Eastern importers, as well as some against South American drawees, bear the clause "payable with interest at 6 per cent. per annum from date of issue to approximate due date of arrival of cover in New York." The use of that clause varies according to the country in which draft will be collected, and according to the terms of sale agreed upon between buyer and seller.

Why Importers Demand Credit

The reason for the foreign customer's willingness to pay costs of discounting drafts is identical with the reason for his demand for credit. In most foreign territories, particularly in South America and the Orient, money rates are high. Local banks charge borrowers anywhere from eight to eighteen per cent. for money advanced. The local importers who does business with American manufacturers on a cash basis therefore penalizes himself by paying the high money rate, if there is any chance of securing goods on credit terms that permit him to pay 6 per cent. for the accommodation under time drafts.

European exporters have always recognized this condition, and, for the money rate, have been liberal in credits. That is they have been willing to sell foreign buyers under "documents against acceptance of draft" terms, whereby the purchaser obtained accommodation on a six per cent. basis, and the discounting banker carried the credit. In between the American manufacturer and his foreign customer comes the banker. The banker really extends the credit when he discounts a draft. The banker is protected primarily by the endorsement of the manufacturer. At the foreign end, the banker is protected by the control of the shipment itself, which is represented by shipping documents attached to the draft. The foreign buyer cannot obtain the shipment until he has paid or "accepted" the draft in the banker's possession. The act of acceptance consists in the endorsing of the draft by the buyer abroad with his signature and the date. Not until such acceptance or payment can the buyer obtain the bills of lading controlling the shipment.

Figuring Amounts on Dollar Drafts

In drawing a dollar draft, the American manufacturer has just one thing to bear in mind, the cash amount he must receive to clear himself at time the draft is discontinued. To show how a $1,000 shipment goes forward under a draft for $1,027.50, so that the manufacturer may "break even," consider the following sale to a Buenos Aires customer under the common credit terms of "ninety days." Assume that amount of manufacturer's invoice, including cost, insurance, freight and incidental charges is exactly $1,000. Interest is usually figured from date of sailing, and the charge would cover 150 days; 30 days to Buenos Aires, 90 days for the term of draft, and 30 days for return funds. Interest at 6 per cent. for 150 days is $25. To this should be added the bank's usual collection commission, say one-quarter per cent., or $2.50. The draft by the manufacturer should therefore be for $1,027.50, which, when discounted in New York, would net the manufacturer the needful $1,000.

Dollar drafts should always be drawn with the clause: "Payable at the holding bank's selling rate of exchange for sight bills on New York." Drafts, as well as invoices, marine insurance policy, consular invoices, etc., should be drawn in duplicate, so that the extra set can be sent forward by a different steamer, to protect against possible loss of originals in the mail.

Collection Instructions Required

American manufacturers should always provide bankers with definite instructions as to conditions under which controlling documents (bills of lading, and insurance policies) should be surrendered to drawees. That is, whether such documents are to be delivered upon "acceptance" of draft—or against "payment." In certain lines the custom is to ship goods under time drafts, but to deliver documents only upon payment. The goods remain under control of the collecting bank for the time intervening before payment. In these matters, bankers always require instruction, as well as on the "protesting" of unpaid or unaccepted drafts. Procedure in drawing drafts often varies, according to the country of destination. In Australia, for instance, an important "colonial clause" on sterling drafts simplifies the figuring of interest and exchange, while a charge from draft to cheque form for collections on certain European countries saves appreciable amounts for stamp fees.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

CANADIAN FAIRBANKS-MORSE PENSION FUND

BECOMING effective January 1, 1917, a pension plan has been put into operation by the Canadian Fairbanks-Morse Co., according to an announcement by H. J. Fuller, president. It has been inaugurated by the directors of the company as an evidence of their appreciation of the faithful service of their employees, the system applying to all salaried employees fulfilling certain conditions.

The members of the fund shall consist of the officers and salaried employees of the Canadian Fairbanks-Morse Co., who have been in the employ of the company for six consecutive months, together with such other classes of employees as may be hereafter determined upon by the directors. In the term "salaried employee" are included all the employees at the head office, and at branch houses and sales warehouses, irrespective of the basis of payment.

Contributions are to be deducted from the individual pays and credited to the fund at the rate of 3 per cent. in equal monthly or weekly instalments, which cease when the contributor becomes a pensioner, and do not apply to portions of salaries above $4,000 per annum. The company on its part will contribute to the fund 3 per cent. annually of the amount upon which individual contributions are based, this sum being payable in monthly instalments. All present and future officers of the company, both male and female, eighteen years of age and over, will be required to contribute, excepting such as may be excused by the directors. Male and female contributors who have been continuously employed for not less than twenty years may be retired voluntarily or otherwise, and become eligible for a pension on attaining the ages of sixty and fifty years respectively.

The annual pension allowance for not less than twenty years' contribution is at the rate of 2 per cent. of the average annual pay (not exceeding $4,000) during the ten years preceding retirement.

for each year of service, with a deduction of an amount equal to 1 per cent. thereon for each year short of twenty.

Various provisions are made for such cases as pensioners' widows, children, etc., also the payment of interest on the fund balance of 4 per cent. per annum.

TRADE GOSSIP

The Boving Hydraulic and Engineering Co., of Lindsay, Ont., have been awarded a contract for a centrifugal pump by the City of Welland, Ont.

Prepare for After War.—Sir George Foster was in conference at Ottawa last Friday with a number of prominent Canadian producers, including representatives of manufacturing, farming, and other interests. Their views were taken on the advisability of holding some time later a national business conference to consider preparation for after-the-war problems. Among those in attendance were F. L. Wanklyn, of the C.P.R., and E. Hebert, of the Chamber of Commerce, Montreal; G. M. Murray, of the C.M.A.; C. A. Bogart, of the Bankers' Association; A. H. Brittain, of the Maritime Fish Corporation, and Col. O. McEwen, of Byron, Ont., representing agricultural interest.

To Develop B. C. Iron Ores.—The Hon. Mr. Sloan, Minister of Mines in the B. C. Legislature, said recently that it was the intention of the Government to do diamond drilling on various iron properties and they hoped within a few months to show a certain amount of ore actually blocked out. We will also, he said, divide the province into mining areas, each in charge of a competent mining engineer, so that the Government will be gathering data constantly. The iron industry, if established in the province, will lead to many other industries and the Government is anxious to bring it here if we can satisfy ourselves that we have the ore in proper quantity and other conditions are favorable.

R. S. White Honored.—A number of customs brokers of the City of Montreal met at the Customs House on McGill street, on Saturday, March 10, for the purpose of bidding a formal farewell to R. S. White, on the occasion of his retiring from office after over a score of years of service as collector of customs. The customs brokers took advantage of the occasion not merely to voice their appreciation of the manner in which Mr. White had performed the functions of his office during that time, but showed their feelings in very tangible form, presenting Mr. White with three superb pieces of silverware, and with an illuminated address. While the ceremony was a very brief one, it was marked by a continuance of the warm personal friendly relations that have always prevailed between Mr. White and those who had business to do with his department, and many feeling tributes were paid him by his friends of the business community. John A. Finlayson presided, and called upon S. Whitaker to present the address.

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address, Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya, Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Montreal, Que.—The G.T.R. has received bids on machine tool equipment for the new shops at Port Huron, Mich.

Hamilton, Ont.—The Union Drawn Steel Co. proposes to build a large addition in connection with its present plant.

Dundas, Ont.—It is understood that the Chapman Engine Co. will rebuild their plant, which was recently damaged by fire.

Ladysmith, B.C. — The Ladysmith Smelter Co. will spend $100,000 on additions to its smelter at Ladysmith. W. J. Watson is superintendent of the plant.

Belleville, Ont.—The Maple Leaf Tires Co. is erecting a plant here at a cost of $100,000, and will be shortly ready for the installation of equipment. O. W. Dunham is secretary.

Edmonton, Alta.—The Western Shell & Box Co. is in the market for an 18-in. engine lathe, about 4 in. belt, for heavy duty; also universal milling machine and dividing head.

Niagara Falls, Ont.—The Herbert Morris Crane & Hoist Co., of Toronto has purchased a site here for a factory. No plans have however yet been definitely decided upon regarding building operations.

Chatham, Ont.—The sale of the plant of the Chatham Bridge Co. to the Pittsburg and Des Moines Steel Co. has been endorsed by the shareholders, and it is expected that the deal will be finally closed within the next few days.

St. John, N.B.—Plans are well perfected for the organization of the St. John Shipbuilding Co., with a capital of one million dollars, to operate under a Dominion charter and construct ships here, at first wooden ones and later steel vessels.

Montreal, Que.—The Thomas Davidson Mfg. Co., will install four 6-ton electrical furnaces at their new steel plant at Cote St. Paul. The electrical equipment will consist of four 1,350 k.v.a. transformers, two motor generator sets, switchboard, etc.

Midland, Ont.—It is understood that the Port Arthur Copper Co. will install a reverberatory furnace at the reduction plant at Midland for smelting copper ores. This furnace will be operated in combination with the company's blast furnace, and will be ready, it is stated, for ore by May 1 next.

Toronto, Ont.—The Town Council's application to grant aid to the British Chemical Co. by granting exemption from all taxes "except school taxes" to pay $10,000 towards the purchase of site for the works of the company and close certain streets laid out on plan site was granted.

Port Hope, Ont.—J. N. Kittson and associates of Hamilton, Ont., have purchased the plant of the Brandon Shell Manufacturing Co., Port Hope. The new firm will have the balance of the machinery installed at once and proceed with all possible speed with the manufacture of shells.

Goderich, Ont.—Final arrangements have been completed whereby the town disposes of the plant known as the Doty Marine & Engine Co., the purchaser being W. H. Hutchinson, of St. Catharines, Ont., contractor of section two of the new Welland Canal. It is understood that the purchase price is $30,000.

St. Thomas, Ont.—Motor radials for a number of routes in Elgin and Middlesex counties were announced on March 15 after the organization meeting of the Interurban Motor Co. The company is capitalized at $100,000, and will operate large motor buses, each capable of seating 26 persons, as well as heavy freight trucks, from St. Thomas to Aylmer and return, from Union to Sparta and return, and from Delaware to Lambeth and return. W. N. Warburton is the general manager of the company.

ELECTRICAL

Havelock, Ont.—The Town Council decided to ask the Hydro-Electric Commission to supply power to the village.

Melfort, Sask.—A new switchboard will probably be installed at the central telephone exchange. The cost is estimated at $1,000.

Brussels, Ont.—The introduction of hydro-electric power is being considered. The power would be developed at Inglis Falls, near Owen Sound.

MUNICIPAL

Montreal South, Que.—A waterworks system is under consideration at a cost of about $180,000.

St. Catharines, Ont.—The Town Council contemplate making improvements to the waterworks plant.

Leamington, Ont.—The Town Council contemplates installing a tank with a capacity of 900,000 gallons.

Oakville, Ont.—The Acme Rubber Co. tax exemption by-law has been finally passed and is now in force.

Midland, Ont.—The by-law to grant assistance to the shipbuilding plant was carried by a substantial majority.

Bridgeburg, Ont.—The Town Council are considering the purchase of a pump and motor for the waterworks plant.

Aurora, Ont.—The Town Council contemplate installing a sewage disposal plant. James, Loudon & Hertzberg, of Toronto, are the engineers.

Toronto, Ont.—Work on the new Don incinerator has been practically completed and operations will commence, it is expected, about the end of this month.

London, Ont.—The Utilities Commission has decided to connect the Foster wells with the city system, at a cost estimated at $47,000. Two new wells will be sunk at once.

Oshawa, Ont.—The Town Engineer has submitted his report to the Council on the installation of new filters and improvements to the sewage plant. The report was adopted.

Montreal, Que.—The Board of Control will proceed with the construction of the LaSalle bridge and the head-gates to be placed at the intake of the aqueduct.

Penticton, B.C.—The City Council contemplate extending the civic power plant and installing additional equipment which would consist of a Diesel engine and electrical machinery.

Cobourg, Ont.—The ratepayers carried a by-law granting the Cobourg Felt Co. a loan of $10,000, which is secured by a mortgage on the plant, and is to be repaid in ten annual consecutive instalments of $1,000 each.

Windsor, Ont.—A by-law will be submitted to the ratepayers on March 26 to grant aid by way of a bonus to Max Goldman and Samuel Harris, who propose to carry on the business of smelting and refining brass and other metals.

Windsor, Ont.—Peter Osterhout proposes to erect a factory for making cement, brick and other products. A by-law will be voted on by the ratepayers on March 26, to authorize aid in the form of a bonus for this industry.

St. Hyacinthe, Que.—A mechanical filtration plant will be installed here having a capacity of four million gallons per day. The filters will be supplied by the Roberts Filter Mfg. Co., of Darby, Pa. Pumps, steam turbine and electrical equipment will also be installed.

Renfrew, Ont.—The Town Council has decided to pass a by-law giving M. J. O'Brien the right to run wires from his plant at Calabogie into the town, but the town will buy power from him and deliver it to users, making purchases from him only after all the civic power available is in service. Permission is given for the carrying of power from Calabogie through the town for delivery in other municipalities.

New Toronto, Ont.—The New Toronto Council, at a special meeting on March 13, instructed the engineers to prepare plans for waterworks extension amounting to about $40,000. This will include a new sedimentation well, two new pumps, pump-house extension, and mains on New Toronto street and Eighth street. The municipality owns approxi-

mately 200 feet of lake frontage and propose building a stone set wall.

Saskatoon, Sask.—The Finance Committee has the following expenditures under consideration in addition to the proposed incinerator: Cold storage plant, $6,000; water softening plant, $14,800; ash handling plant, $10,000; motor chemical truck, $1,000; fire alarm boxes, $2,500; street railway improvements, $16,640; two street cars, $15,000; motor generator for police and fire patrol signal systems; alternating power house boilers, $7,000; completing force water main contract, $25,000, and electrical connections, $6,000.

GENERAL

Chambly, Que.—The Canadian Leatherboard Co. will build a factory here.

Trenton, Ont.—The T. Eaton Co., of Toronto, have purchased a site here for a creamery. Building will start at once.

Windsor, Ont.—The Canadian Oil Co. propose establishing a business for making lubricants, oils, paints, etc. A factory site will be given the company provided a by-law passes on March 26.

Winnipeg, Man.—The terminal elevator of the Northern Elevator Co., situated on the C.P.R. tracks, was destroyed by fire on March 9. The estimated loss is about $150,000, including building contents and machinery.

London, Ont.—The Hunt Bros.' City Mills will not remove from London. The city retains this industry through the efforts of the Industrial Commission, which has just completed an arrangement whereby the present mill site and water rights are purchased for $15,000 by the Public Utitlities Commission. The latter will get new tenants, while the Hunts will commence the erection at once of a $150,000 plant in the east end.

Victoria, B.C.—The announcement was made at Bellingham recently by John E. Rice, president of the Lummi Bay Packing Co., that it was the intention of that concern to build two salmon canneries this spring on Vancouver Island. The main cannery will be at Nitinat and the other close to that place. The two plants will cost approximately $100,000. A cold storage plant is included in the company's plans, in addition to which they will build five tenders and seine boats for the use of the two canneries.

TENDERS

Toronto, Ont.—Tenders will be received for a building until April 9, addressed to the Toronto Harbor Commissioners, 50 Bay Street, Toronto, Ont.

All information may be obtained by applying to the Architects, Chapman and McGiffin, 95 King Street East, Toronto.

Toronto, Ont.—Tenders, addressed to the chairman of the Toronto Electric Commissioners, will be received until March 28 for synchronous condensers. Specifications may be obtained at the office of the purchasing agent, 15 Wilton avenue, Toronto.

Cartwright, Man. — Tenders will be received by the Rural Municipality of Roblin up to April 5 for abutments and steel work for four bridges. Plans, specifications and tender forms may be seen at office of Highway Commissioner, Winnipeg, or at the office of Secretary-Treasurer, Cartwright, Man.

Toronto, Ont.—Tenders for synchronous condensers, addressed to the chairman of the Toronto Electric Commissioners, will be received until March 28. Specifications, form of tender and all information desired may be obtained at the office of the purchasing agent, 15 Wilton avenue, Toronto.

Toronto, Ont.—Tenders will be received up to April 2, addressed to the chairman of Toronto Harbor Commissioners, 50 Bay street, Toronto, for the construction of harbor head walls. All information may be obtained by applying to the above address. E. L. Cousins, chief engineer and manager.

St. Felix de Valois, Que.—Tenders will be received until March 31, at the office of the corporation of the parish of St. Felix de Valois, for the construction of an iron bridge in this parish. The plans and specifications can be seen every day at the Office of the corporation. J. H. Lavallee, sec.-treas.

Hamilton, Ont.—Tenders addressed to Chairman of Board of Control will be received up to April 5 for the supply and delivery of one combined motor driven flusher and sprinkler to conform to the following general specifications: Tank capacity, 1,200 Imperial gallons; truck not less than 5-ton; separate motor for flusher apparatus. Further particulars on application to the Secretary of Works Department, City Hall, Hamilton.

Quebec, Que.—Tenders, addressed to the secretary-treasurer of the Municipality of Halifax South, will be received until March 25, for the construction of two highway bridges, with steel superstructure, concrete abutments, approaches, etc., on the Frontier and Pigeon Rivers (ten arpents distant) in the parish of St. Ferdinand d'Halifax, Megantic county. Plans and specifications may be examined at the Council's office and at the Department of Public Works and Labor, Quebec.

CONTRACTS

Montreal, Que.—It is understood that the Canadian Car & Foundry Co. have received an order for 2,000 freight cars from the Russian Government.

Victoria, B.C.—It has been announced by Capt. J. W. Troup, manager of the B. C. Coast Steamship Service, that Clarence Hoard, of this city, had been awarded the contract for the building of one of the C. P. R. car-barges, and that possibly Mr. Hoard, who is a well-known contractor, would also secure the contract for the second barge which the C. P. R. decided recently to have built here. Each of the barges will have a capacity for holding nine cars.

PERSONAL

James P. Wood, a member of the firm of Wood Bros., foundry, died at Chatham, Ont., on March 16, aged 45.

A. E. Johnson, engineer, Dominion Bridge Co., Montreal, is visiting New York in connection with some large contracts.

D. J. McCuaig has been appointed acting master mechanic of Ontario lines, with headquarters at Toronto, in place of **W. G. Sealey**, assigned to other duties.

George Forest McKay died at New Glasgow, N.S., on March 13, at the age of 82 years. Mr. McKay assisted in the founding of the Nova Scotia Steel & Coal Co., and was its oldest director.

R. M. Hoffman has recently been appointed manager of sales of the Hesse-Martin Iron Works, Portland, Ore. He is a mechanical engineer, and has been connected with the Messe & Gottfried Machinery Co. in both its Seattle and Vancouver plants.

J. A. Sanderson, a prominent business man of Brantford, Ont., died at his home in that town on March 14. The deceased was a native of this district and was 60 years of age. He was president of the Brantford Carriage Co., and a director of the Cockshutt Plow Co. He was one of the original promoters of the Lake Erie & Northern Railway.

J. W. Norcross, vice-persident and managing director of the Canada Steamship Lines, has been appointed director of shipbuilding in Canada, attached to the Naval Service Department. The Government is anxious to immediately carry out an undertaking for the construction of as large a number of merchant vessels as possible at the various shipbuilding works and dry docks in Canada, and has placed the entire undertaking in the hands of J. W. Norcross, with powers to forthwith proceed with the organization of his staff and the placing of the contracts, in order that the largest number of boats may be launched at the earliest possible date.

Capt. Gilbert Johnston, a well-known figure on the St. Lawrence and the Great Lakes, and long actively connected with the Richelieu & Ontario Navigation Co. and the Canada Steamship Lines, Ltd., died at his residence in Montreal on March 13, after a long illness. He was known to practically all of the river and lake steamboat men in this part of the Dominion, and had a very wide circle of friends and acquaintances. Captain Johnston was of Scottish ancestry and was born in Kingston, Ont., sixty-four years ago, being a son of the late Gilbert Johnston. In 1894 he was appointed mechanical superintendent for the Richelieu & Ontario Navigation Co., a position which he filled with conspicuous success. After receiving this appointment he removed from Kingston to Montreal, and resided here for the remainder of his life. He retired from active work with the Canada Steamships, Ltd., six months ago.

TRADE GOSSIP

The Canadian Fairbanks-Morse, Toronto, have been awarded a contract for a centrifugal pump by the town of Waterloo, Ont.

The Vanadium-Alloys Steel Co., Pittsburgh, Pa., announce that they have obtained the services of T. C. Chown, 4276 Westmount avenue, Montreal, who will assist P. F. Fosnight, the company's Canadian manager.

The Wells & Gray Co., contractors, Toronto, have been awarded a contract for a sporting goods factory for the Peters Cartridge Co., Cincinnati, Ohio, to cost around $300,000.

The Ætna Iron & Steel Co. has moved its offices from Victoria, B.C., to 916 Standard Bank Bldg., Vancouver. The company has leased with option of purchase the Port Moody Steel Works. The entire plant is being rearranged and a new open-hearth furnace is being constructed. David Milne is the managing director.

The James McKay Co., Pittsburgh, maintains an office in charge of John A. Buchanan in the King Edward Hotel in Toronto, Ont. The company is selling a large part of its output in Canada, comprising mechanical, marine and stud-link marine chain, anchor shackles, hooks, etc., and commercial and special forgings.

Brown's Copper & Brass Rolling Mills, Ltd., New Toronto, Ont., have erected a handsome office building adjacent to their mills on the Lake Shore Boulevard, which is practically ready for occupancy. Extensive additions to meet their expanding business have been added to this company's plant during the past two years, which has necessitated larger quarters for their executive staff.

The United Hammer Co., Boston, Mass., have purchased the power hammer business of E. & T. Fairbanks & Co., St. Johnsbury, Vt. The "Fairbanks" hammers were manufactured from 1890 to 1902 by the Dupont Mfg. Co., of St. Johnsbury, under the name "Dupont" hammers. In 1902 the business was taken over by E. & T. Fairbanks & Co., who changed the name to "Fairbanks" hammers, which title will be continued by the United Hammer Co.

Ontario Metal Output.—Increases in the total mineral output of the Province of Ontario, according to a report just issued by the Bureau of Mines, was valued at $64,843,597, an increase over the preceding year of $10,597,918. The report points out that the expansion in the production of minerals in this province was mainly confined to gold, nickel, copper, cobalt, molybdenum and lead. This was in large part a result of the war and consequent high prices for metals. The increase in valuation over 1915 is confined to metallic products, the total for non-metallics showing a small decrease.

Goodyear Tire and Rubber Co.—The new plant for the Goodyear Tire and Rubber Co., which is being constructed at New Toronto, will be completed about May 1. The building is 560 feet long by 80 feet wide, four storeys and basement and will cost $1,500,000. The stack is 14 ft. diameter and 250 ft. high. Approximately 600 men will be employed when the plant is opened, but the factory is large enough to employ 1,500 men. The Goodyear Company own 28 acres at New Toronto, and propose to build six factories of similar size as their business grows.

Brown's Copper & Brass Rolling Mills, Ltd., New Toronto, Ont., announce that they have awarded a contract to the Southwark Foundry & Machine Co., Philadelphia, Pa., covering the installation of a 2,000-ton hydraulic extrusion press equipment for the manufacture of brass rod. This machine will be in operation during the early part of May, and with their present equipment in their new rod mill will increase their output to over five million pounds of finished rod monthly. Their new mill for sheet metals will also be in full swing during May, 1917, increasing the output of their sheet mills to over five million pounds monthly.

Northern Navigation Co. Hold Meeting.—The three days' annual "Get Together" meeting which was held at the offices of the Northern Navigation Co., at Sarnia, Ont., was brought to a close on Friday. The men were gathered together for the purpose of discussing new methods and plans for the coming navigation season. A great benefit is derived by the different officials at a meeting of this kind exchanging views and offering suggestions for the good and welfare and popularizing this well-established line which conveys thousands of passengers and tourists on the Great Lakes every year. The prospects for a big season are very bright, and optimism permeated the meeting. The following officials were among those in attendance: H. H. Gildersleeve, general manager, Sarnia; W. H. Smith, agent of Owen Sound; C. H. J. Bowden, travelling freight and passenger agent, Montreal; W. L. Day, travelling passenger agent, Sarnia; Fred Bentley, chief clerk, Sarnia.

MARINE

Captains Appointed.—The Northern Navigation steams this year will be commanded by the following officers: Noronic, Capt. Foote; Hamonic, Capt. A. L. Campbell; Huronic, Capt. A. M. Wright; Germanic, Capt. F. G. Moles; and Waubic, Capt. John Dube. All the steamers are being fitted out and will start their schedule as soon as ice conditions will permit.

Montreal, Que.—It is expected that navigation will open about April 15. Officials of the Harbor Board predict that it will be considerably earlier this season than for some years past. April 15 is generally set as the date when the St. Lawrence channel will be sufficiently free from ice to permit of vessels coming into port. According to tests recently made, ice in the basin of the harbor is not more than four inches thick, and this is said to indicate that the break up is not very far distant. According to pilots there is not ice at all between Quebec and Grondines, and that the ice is comparatively smooth from the latter point up to Montreal.

London, Ont. — Work will be undertaken within a few days, according to report, on the new $130,000 Government pier at Port Stanley, to be constructed at the request of owners of the fishing fleet at the port and of the London and Port Stanley Railway Commission.

BUILDING

Montreal, Que.—Damage to the extent of $3,000 was caused by a fire on March 13 in the warerooms of the Cassela Color Co., 59 William Street, which occupies the buildings recently vacated by the Canada Cold Storage Co., the owners.

Toronto, Ont.—Dr. C. J. O. Hastings has recommended to the Local Board of Health the erection of a hospital for infectious diseases, to cost $75,000. The Board decided to hold a joint meeting with the Property Committee to consider the proposal to build on the western part of the jail grounds.

Mitchell, Ont.—The contract for the erection of the new agricultural building to replace the one burned down last fair day has been let. The contract price will be in the neighborhood of $3,000. The building will be circular and 70 feet in diameter. Most of the material is now on the ground, and the building will be erected during the summer.

RAILWAYS—BRIDGES

Toronto, Ont.—Works Commissioner Harris is inserting in his estimates an item of $200,000 for a new bridge across Rosedale ravine at Glen road. It is stated that this bridge will have to be constructed before the Bloor street viaduct is completed, in order to facilitate access to Howard street from the north.

INCORPORATIONS

Feldspar Quarries Ltd., has been incorporated at Toronto with a capital of $40,000 to develop mines and quarries, etc. Head office at Toronto and provisional directors are Fred A. A. Campbell, D. B. Coleman and William Zemmerman all of Toronto.

Canadian Electric & Gas Heater Co., has been incorporated at Ottawa with a capital of $250,000 to manufacture gas and electric stoves and heaters etc., at Montreal. Incorporators are C. J. E. Charbouneau, James E. Coulin and Philippe Morel all of Montreal.

The National Shipbuilding Co., has been incorporated at Ottawa with a capital of $100,000 to carry on the business of iron founders, millwrights, machinists and shipbuilders at Goderich, Ont. The incorporators are W. H. Hutchinson of St. Catharines, Ont., Robert G. Stewart and Ernest A. Larmouth both of Ottawa, Ont.

CATALOGUES

The American Pulley Co., Philadelphia, Pa., have issued a booklet entitled "Building 25," descriptive of a new building recently opened at the plant for the convenience of workmen and for safeguarding their health. The booklet contains descriptive matter, and also a series of photographic views showing the principal features of the building, embodying the latest ideas applied to the preservation of health in factories.

A. C. Generators.—T. W. Broadbent, Ltd., Huddersfield, England, have issued a new bulletin, No. 4, dealing with their T. Type three-phase generators, designed especially for motor driving. A full description is given of this machine, accompanied by illustrations, while a price list is included, giving capacity and weights for each size of generator and exciter. Copies of the bulletin may be obtained on application.

Water Heaters.—The Alberger multi-head water heater for hotels, office buildings and factories, is described in a Bulletin No. 201 recently issued by the Alberger Heater Co., Buffalo, N.Y. The principal constructional features of the multi-head heater and their advantages are described fully, special reference being made to the method used in the heater to accommodate unequal expansions. The bulletin is illustrated.

Row & Davis, Engineers, Inc., 90 West street, New York, have just published two interesting bulletins, copies of which will be mailed to readers on request. "The R. & D. Paracoil "Evaporator," Bulletin No. 51, for single or multiple effect operation. The bulletin shows and describes the evaporator thoroughly. The most interesting feature, perhaps, is the patented new type of manifold, which is mounted on a hinged door to facilitate inspection, cleaning, etc. Bulletin No. 52, "The R. & D. Feed Water Heater" fully describes the shell, manifolds, coils, connections and fittings of their heater. These bulletins should be in the hands of every engineer interested in feed water heating and water distillation.

Galt Sprinkler Stoker.—The Galt Foundry Co., Galt, Ont., have issued an attractive catalogue dealing with the economic and smokeless burning of coal, including lignite, and at the same time featuring the Galt sprinkler stoker. A full description is given of this type of stoker, and its principal feature dealt with in detail, accompanied by numerous illustrations showing the construction and application to various types of boiler. The concluding pages contain some useful engineering data covering evaporation formulae, heat values of coal, feed water calculations, miscellaneous tables, etc. The catalogue also contains instructions for reading the slide rule, accompanied by diagrams. The McNaughton rocking sectional grate bar is also described and illustrated. The catalogue is well gotten up, being printed on coated paper, with exceptionally clear half-tones.

Ball Bearings for Transmission. — The Chapman Double Ball Bearing Co., of Canada, Ltd., Toronto, have issued to the trade a new 48-page bulletin No. 107. This bulletin, which is a very attractive publication, illustrates and describes fully, a standard line of power transmission bearings. Among the illustrations are included a number of sectional views of bearings showing the principal features embodied in their design. The section of the bulletin devoted to the development of the Chapman double ball bearing contains much useful information covering the design and scientific features of this bearing, while details of tests are also included with views of the apparatus used for the tests. The application of ball bearings for loose pulleys and pillow blocks is also dealt with, fully accompanied by dimension tubes and price lists. One interesting feature comprises a number of excellent full page half-tones, showing a variety of power transmission installations equipped with the Chapman product, and also interior views of the company's plant.

BOOK REVIEW

"Combustion in the Fuel Bed of Hand-fired Furnaces," is the title of Technical Paper 137, by Henry Kreisinger and others, which has just been issued by the Bureau of Mines of the Department of the Interior, Washington, D.C. The main object of the investigation was to determine the conditions governing the process of combustion in the fuel bed of a hand fired furnace. The results of this investigation furnish data for correct design of coal-burning grates and furnaces and their efficient operation. They also cast light on the important problem of clinker trouble as related to fusibility of ash. They further indicate the possibility of a high rate of gasification of coal in gas producers. The first part contains general information on the combustion of coal in furnaces. The second part contains the description and the results of about fifty tests made in a small experimental hand-fired furnace, which was designed for an accurate study of the processes of combustion in the fuel bed. The third part discusses the investigations described in the second part of the report, and includes about forty charts that show the composition of the gases and the temperature at different depths in the fuel-bed of a hand-fired furnace, and various relations between the air supply and the rate of combustion. The fourth part contains miscellaneous data on the composition of gases rising from the fuel bed of a hand-fired furnace under a steam boiler, a Murphy stoker, and a Jones underfeed stoker. It also contains a short discussion of the bearing of the results of the experiments on the operation of gas producers and explosions in boiler furnaces. Copies of this technical paper may be obtained free of charge by addressing the Director of the Bureau of Mines, Washington, D.C.

CANADIAN MACHINERY

AND MANUFACTURING NEWS

A weekly newspaper devoted to the machinery and manufacturing interests.

PREPARING A LARGE SIEGE GUN FOR ANOTHER ROUND ON THE WESTERN FRONT.

Special Machine Tools Developed for Shrapnel Manufacture

Contributed

Special interest attaches to the machines described in the accompanying article in view of the fact that they are the product of actual experience in shell machining. Previous to undertaking shell work, the concern building these machines was engaged on work widely different from machine tool building, which thereby enhances its reputation as a shell producer.

THE manufacture of shrapnel shell, by reason of the light weight and small dimensions, lends itself very readily to the use of single purpose machines, and the degree to which operations have been simplified and the possibility of error removed has been one of the principal factors contributing to the successful carrying out of large scale shell production. A detailed tracing of the work during progress is also essential in work of this class, and the illustrations which we reproduce herewith will enable the salient features of such work to be easily grasped by readers familiar with shell manufacture. The machines are the product of the T. H. Symington Co., Rochester, N.Y., and have been developed under actual production conditions, in a factory having a capacity of 15,000 finished shell and sockets per day.

FIG. 1. DOUBLE RING WHEEL GRINDER FOR SQUARING BASES.

Single-purpose machines to the number of about twenty are available, several of them being adapted for high explosive shell work as well as shrapnel, while nearly every type of machine can be utilized as a unit in an existing shell system, so that users of other types of machines can select such of the Symington machines as fit into their present outfit. This elasticity is a desirable feature and is obviously preferable to a system where the rotation of operations is dependent on the procuring of a large number of different machines more or less dependent on each other for successful production.

Progress Report

The progress report sheet reproduced is to a great extent self-explanatory. It will be noted that in "Type" column, the only equipment not indicated as Symington designs are furnaces, press, marker and drill. Fig. 1 shows a double ring wheel grinder of simplest possible design, for squaring the closed end of the rough forging before either cutting-off the open end or centering. The forging is held in a vee-block by hand and the table swings across the face of ring wheel which grinds off the portion of the base required for centering. Mention might be made of the stop bars for limiting the swing of the table, thus preventing the shell from passing clear of the face and being inadvertently pushed along the vee-block so as to foul the outside of wheel on the return stroke. The ring wheel chucks have a diameter of 12 in.

The cutting-off machine is designed for all types of 3 in. shells and consists of a unit type bed similar to that shown in Fig. 9, with suitable tool carriage and gauge rod device. The hinge chuck has three inserted jaws ground to diameter of shell forging. The point of cutting-off is gauged from the bottom of the bone by a gauge rod sliding in a bracket fitted with a spring stop pin which engages with a slot in the rod when the shell is pushed into the spindle the proper distance. A spring plunger is provided in the spindle which keeps the shell against the gauge rod, while the chuck is being tightened up. The cross slide has power feed with automatic trip.

Nick-Centering

The open end is now nick-centered on a simple type of drop stamp, the object being to produce a series of nicks around the inside edge of the mouth to fit the spur drive centre used on the rough turning lathe, Fig. 4. The anvil of the stamp is provided with an arbor for supporting the shell, and a solid block is inserted around its base with chisel points which form the nicks when the die block is dropped on the closed end of the shell.

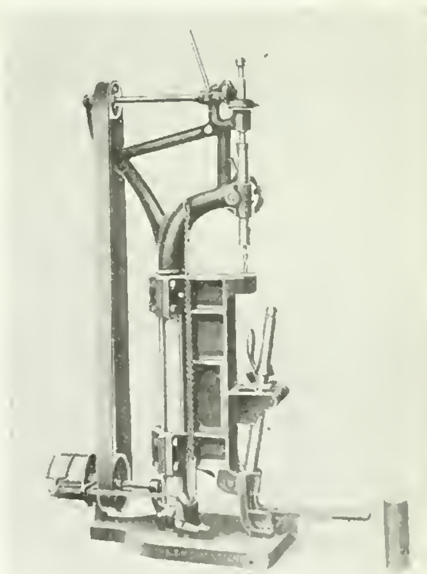

FIG. 2. CENTERING MACHINE WITH TILTING, EXPANDING ARBOR.

These nicks provide a very powerful means of driving the blank and enable the shell to be turned complete from base to nose without interference from chucks, drivers, etc.

The machine shown in Fig. 2 centers the closed end by drilling in the usual way. A swinging arbor with expanding jaws at the point is operated by a foot lever which thus centres the base of the shell from the inside, while the open mouth is centered on a conical collar. This machine is sometimes used for spot facing the closed end instead of grinding on the ring wheel grinder.

Turning the Body

Shell turning lathe type B-8 is shown in Fig. 4. The shell is held in centres, the spur drive centre being clearly shown. A single tool block is provided in front, and the carriage operates on a flat profile cam to turn different shell diameters, a powerful spring holding carriage up to cam. The carriage is further equipped with a cam relief for returning the carriage to starting point without scoring the work. A similar machine, type B-1 is equipped with ¾ in. square tools front and back, the front tool taking the greater part of the cut, and the back one following about ⅛ in. behind with a light cut; this machine, however, produces a parallel shell only.

The machine shown in Fig. 5 is designed for boring the inside body of the shell down to the diaphragm seat. The same design of bed is used for this machine as in the rough turning lathe, the spur drive centre being replaced with a hinge chuck while the tailstock is removed. The inserted tool steel jaws are ground to shell specifications, and the carriage is fitted with power feed having automatic trip. Where shells are bored taper, the cross-slide is arranged to work against a profile cam on the back of the machine, thus boring the shell to profile. The bar is equipped with cutting tools for machining the bore, and is slotted on one side and a copper tube sweated in for conveying the lubicant directly on to the tool point. A similar machine having the power feeds replaced by a fine hand-worm feed is used for roughing the powder pocket.

Inside Finishing

Inside finishing is done with machine type B-2, Fig. 6, which is fitted with a triple tool cross slide which can be tooled up to any particular specification of shell: for instance, the first tool hole can be connected up for form boring and for this work the cross slide is guided by a hardened roll held against a profile cam by a heavy spring back of the machine. For finishing the bottom or powder pocket of the shell, which requires a heavy pressure, a powerful hand worm feed is attached to turret carriage which makes this operation easy. The shell blank is gauged from the open end by a stop in the chuck guard and a spring plunger inside of the spindle. Rough facing of the base is done in the same machine as is used for cutting-off, the tool holder being changed to suit requirements.

Operations from No. 10 to No. 17 may be performed in suitable equipment which happens to be available, although in the case of large productions such as are obtained by the Symington Company the operations of heat treating and nose closing is handled on an exceptionally large scale which permits the use of furnaces and handling arrangements not commercially feasible with small plants.

Nose Finishing

The machining of the nose includes boring, reaming, tapping and undercutting, and is done on a similar machine to that used for finishing the interior. The shell is held in a four-jaw spring chuck with open end facing the tools. The carriage is equipped with hand feeds only and has a cross slide with four tool holes bored to 1¾ in. dia. This slide is indexed with pin to locate holes centrally with spindle, and is customarily fitted up with tools for rough boring, finish boring, tapping and undercutting, also for form boring on interior profile of nose.

The finish turning of the shell is done complete, including the profile. The threaded nose has a socket screwed in which fits the screw drive in the spindle nose. The centre which is still in the bottom of the shell is supported by the tail stock. A profile cam controls the travel of the tool which starts at the base end of the shell and travels the full length of the shell right to the nose. A cam relief is equipped for returning the car-

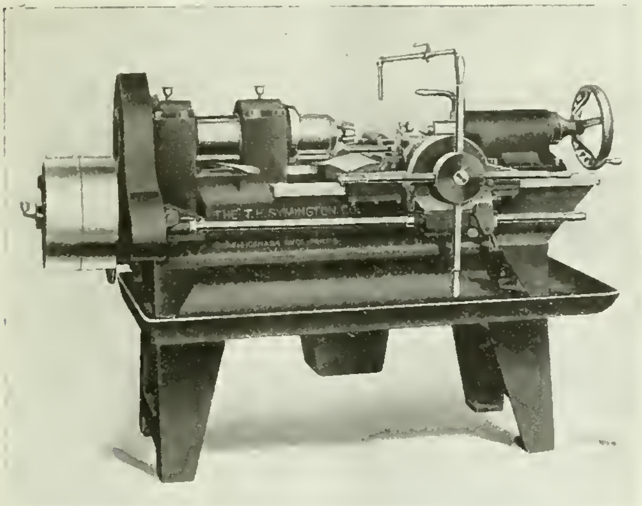

FIG. 4. ROUGH TURNING LATHE WITH SPUR DRIVE CENTRE AND PROFILE CAM.

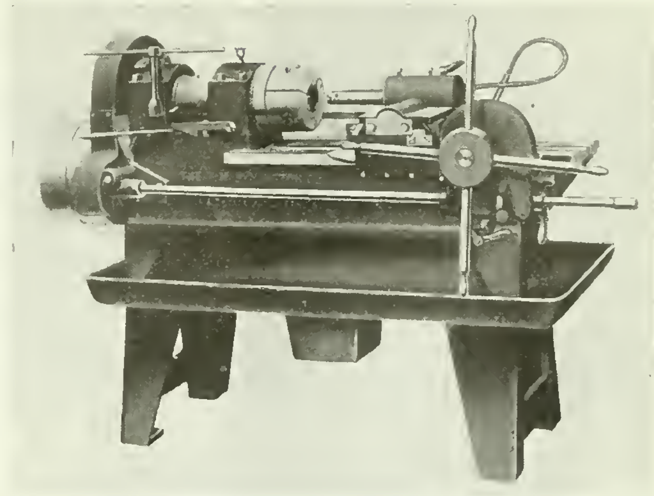

FIG. 5. SHELL BORING MACHINE WHICH CAN BE ARRANGED FOR TAPER WORK.

riage to starting point without scoring the work.

A Cylindrical Grinder

Convincing evidence of the completeness of the line of machines and the versatility of the designers is afforded by the grinding machine illustrated in Fig. 8, which is for grinding the bourrelet or forward land in Russian shells and such outside diameters as are required in other types. This machine is equipped with hand feed only to the table, which is provided with three stops for three different diameters of finished body. Drive is direct from the line shaft by mounting a clutch with extended sleeve for holding the cone pulley which gives two speeds to the wheel head. The work-head drum is also driven direct from the line shaft and has a clutch so that work can be stopped and examined without stopping overhead works. Tailstock is equipped for holding the diamond for truing the face of the wheel. Size of wheel used is 18 in. x 2 in. x 5 in., and runs in bearings of the taper cone type made of special alloy bronze.

For removing driving centres or tits from the base after boring and finish turning operations are completed, a machine with long bed as in type B machines is used. A hinge chuck for the shell is mounted on the carriage in line with the spindle. The spindle carries a bar which holds a high-speed steel cutter and also a stop pin arranged to operate when the tit has been completely removed.

Grooving, Waving, Etc.

Groove operations are divided over two machines of the A type, one of which does rough grooving and forms radius on corner of base, while the other, Fig, 9, waves and undercuts. The main features of these machines are identical, being of the short bed or chucking type as compared with the B type which has a long bed for using a tailstock or turret carriage.

In roughing the groove, the front tool block holds a circular form tool, the hand wheel to cross slide being indexed for depth of groove, and a fine hand worm feed for increased leverage fitted to feed screw. The radius tool is of circular form, and is held in a swing fixture to allow for maximum and minimum thickness of base and also allow for slight variations in concentricity of base of shell.

In waving and undercutting, the shell is held in hinge chuck with a spring stop in the spindle, see Fig. 9. The shell is pushed in against this spring stop, and a swing stop on the slide is thrown across the base of the shell, thus locating it in its proper relation to the waving and undercutting tools. The spindle is equipped with a circular wave cam in front of the front bearing. The wave slide works at right angles to the cross slide, and the cross slide hand wheel is graduated for depth of cut of wave ribs. Cross slide is equipped with fine hand worm feed to give leverage to the operation.

Undercutting Tools

The undercut bracket is located on the front of the cross slide and the angle of the bracket is machined to the angle of the undercut of the shell. Both right and left hand undercut brackets are fitted with small slides with adjustable gibs for wear, also with small hand wheels indexed for depth of cut. Flat stock is used for the undercut tools. Provision is made for using either flat or circular form wave tools, and the wave cam slide, when undercutting, is relieved from the cam to prevent vibration.

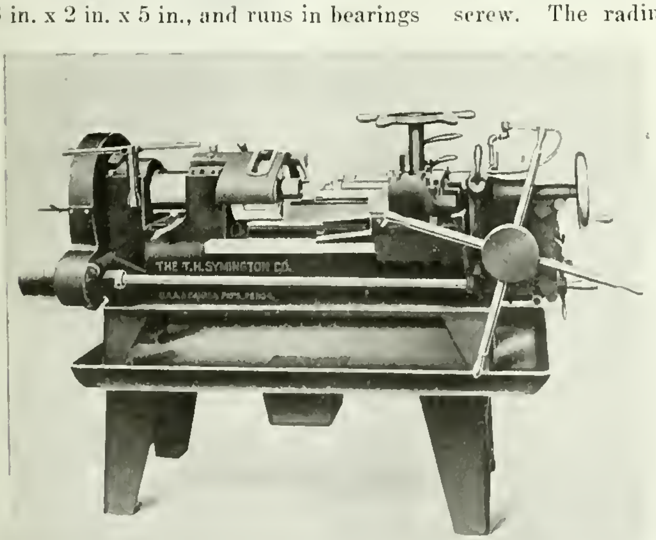

FIG. 6. TRIPLE TOOL BORING LATHE FOR FINISHING INTERIOR OF SHELL.

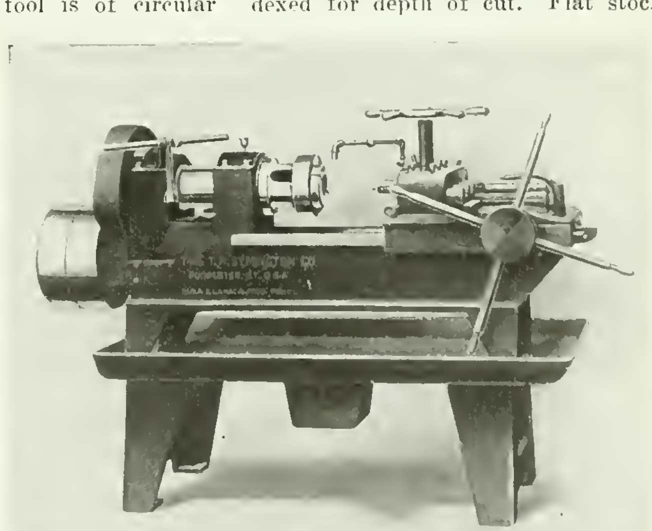

FIG. 7. FOUR-TOOL MACHINE FOR MACHINING AND FINISHING THE INTERIOR.

Band Turning

The next operation which directly concerns these machines is the copper band turning done in type A-4 machine. The shell is held by the base in a collet chuck, while the nose is supported by a cup centre in a tailstock bracket. The turning tool is located on the back of the cross slide and is pulled underneath the shell, turning the band to its proper dimensions. On front of slide is a small handsteady rest for supporting the hand tool with which the operator trims off the burrs from both edges of the band.

The machines illustrated and described herewith are good examples of their kind, and considered as a whole are brimful of suggestion and adaptation for other lines of manufacture. Attention has already been drawn to the fact that two main types have been developed, each of which has been utilized for many operations of widely varying character. The desirable features of this from a manufacturing standpoint are very considerable, allowing of the larger parts being machined up to quite an advanced stage, after which various combinations of standard parts, shafts, feed gears, carriages and chucks, enable rapid assembly to be made for particular shell specifications.

Salvage Operations

At the bottom of the report is another form showing number of fuse sockets finished daily—number submitted for inspection, number accepted, number rejected, and number condemned. Only those condemned are a total loss. Those rejected are sent to what is known as a salvage department, from which they are returned as soon as the defect is remedied. The same plân is adopted with shells under the heading of Operators' Loss. One great advantage of such a report is that a defective or worthless shell rarely gets to the inspection department. The inspectors who have charge of the batteries of machines on different operations, find it possible to discover defects in time, either to discard them or to divert them to the salvage department.

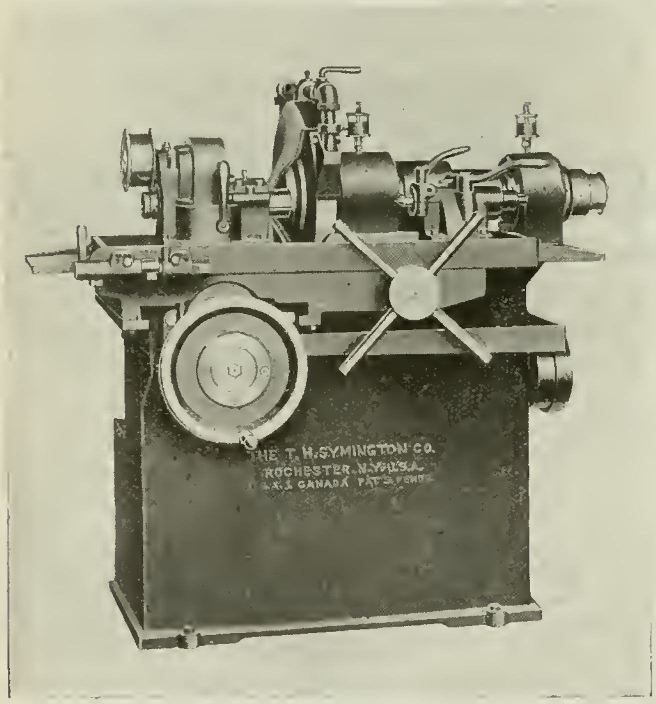

FIG. 8. PLAIN GRINDING MACHINE FOR SHELL BODIES, WITH THREE STOPS FOR BODY DIAMETERS.

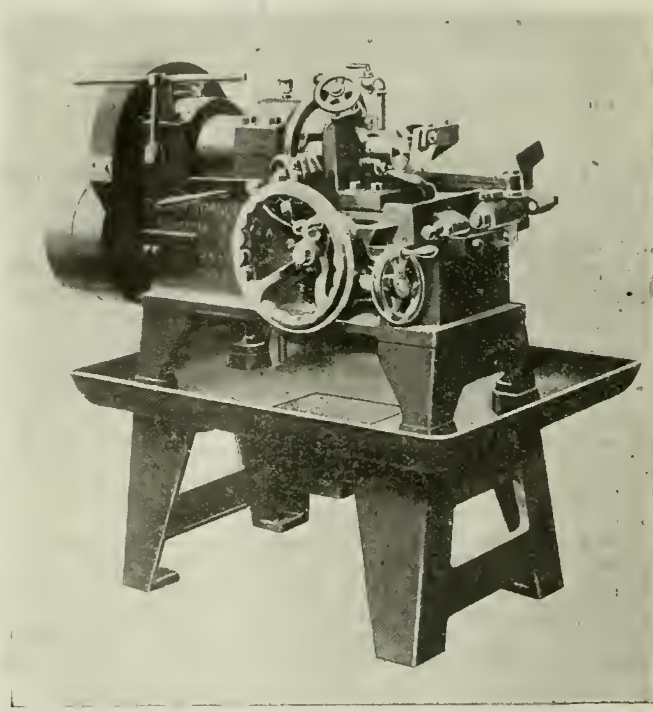

FIG. 9. GROOVING MACHINE WHICH GROOVES, WAVES, AND UNDERCUTS COMPLETE.

SHIPBUILDING HAS ASSURED FUTURE

THE future of shipbuilding in Canada has been the subject of much consideration by the Minister of Trade and Commerce, and has been discussed in more than one private conference during the past few months. Looked at superficially, the recent orders for wooden and steel ships aggregating sixty million dollars for Canadian yards promises a permanent revival of the industry. In that, sixty millions is included the Imperial Munitions Board orders for twenty-five million dollars worth of steel ships, for which extensive plans are being worked out. More than one hundred wooden vessels are said to be planned for on the Pacific and Atlantic coasts, and there is a fairly good hint of efforts to adapt some of our steel making facilities to the work of rolling ship plates and fabricating structural steel of many kinds.

A leading shipbuilder, reviewing the situation, expressed the opinion that while the Imperial Munitions Board may stimulate steel construction for some years to make up for the heavy inroads of the German subs, the Canadian shipbuilding industry, freed from special support of that kind, faces an unpropitious market. Before the war, the British shipyards could produce at thirty per cent. less than Canadian yards. With the speeding up of British methods and the standardization of craft construction, the Canadian competitor could anticipate a forty per cent. handicap when Britain starts looking for orders. The only offset yet suggested is a form of subsidy, and it is a question whether the Dominion Government will proceed to nurture an infant industry under these unusual conditions.

Canada's shipbuilding industry has not made steady advances during the past fifteen years. Between 1901 and 1913—years clear of war conditions—the tonnage built and registered in Canada varied from 30,000 to 50,000, and in 1908 attained 78,000; in the 1915 fiscal year an advance was made to 55,000, and in that year too the tonnage sold to other countries ran to 1,150,000, as against averages of less than 200,000 in the fourteen preceding years.

The prospects of uninterrupted development on the Great Lakes are much better by reason of the protection of the canals from overseas competition in most lines. Whether the wooden ships now being constructed on the Pacific and Atlantic seaboards with high wages and costly materials can withstand the rivalry of British shipyards is a question inviting many sorts of opinion.

Neither Taking Risks.—A tall, gaunt-looking man entered a hotel and applied for a room. The price he was willing to pay entitled him to lodgings on the top floor of the house. Among his belongings the landlord noticed a coil of rope. He asked what the rope was for, and the man replied:—"That's a fire escape. I always carry it with me, and in case of fire I let myself down from the window." "Yes," replied the landlord, stroking his chin reflectively, "seems a pretty good idea, but guests with fire escapes pay in advance at this hotel!"

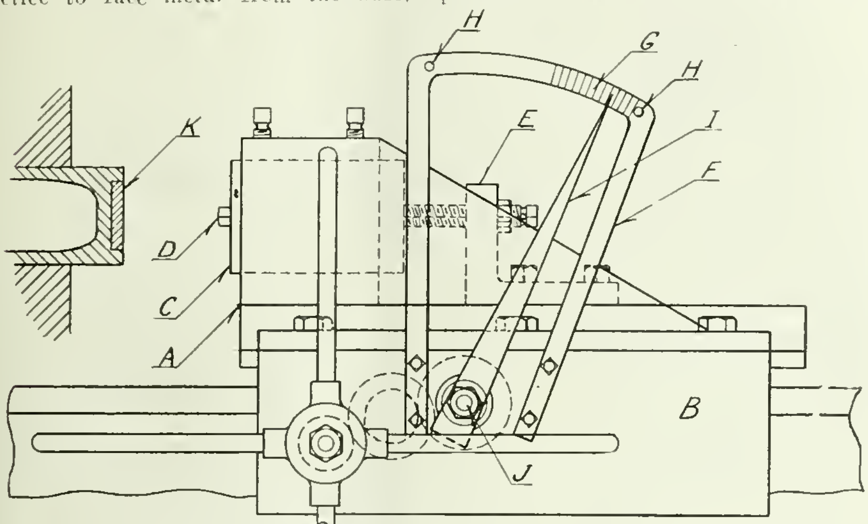
PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

CUTTING SHELLS TO WEIGHT

By R. Hamilton

ONE of the chief essentials in shell manufacture is the necessity of keeping the semi-finished product to the specified weight, so that, when finished, it will be between the high and low limit tolerances. It is a common practice to face metal from the base, after the adapters are riveted in, to bring the shell to the required weight. As an ounce, or fraction thereof, may only represent about a 1-64 inch, it is very often difficult to gauge the exact amount when removing the metal. In a plant recently visited by the writer there has however been devised a simple but very effective method of meeting the requirement, and one that has entirely eliminated such trouble as may have been previously experienced. The accompanying sketch shows in detail the arrangement of the device.



CUTTING SHELLS TO WEIGHT.

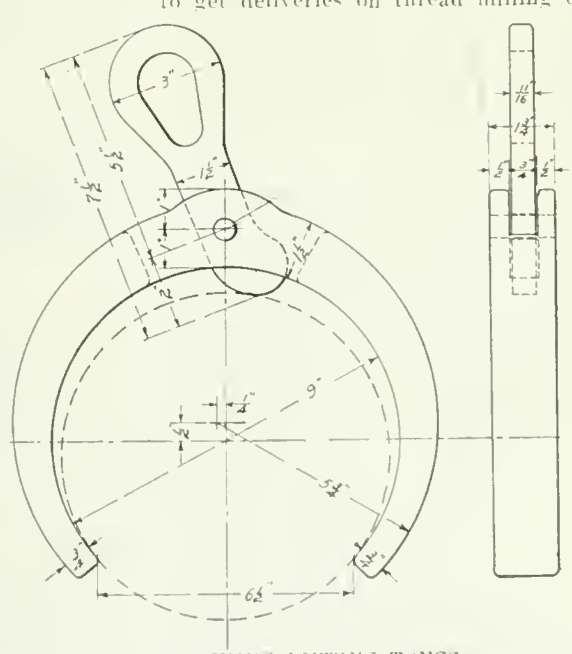
The movable slide A, which travels in the fixed saddle B, carries the tool block C; the broad nose facing tools D being adjusted to position by means of the two rear screws, passing through an angle bracket E, which is secured to the movable slide. Bolted to the fixed saddle B, and extending upwards for about 18 inches, is the inverted U shaped piece F made of band irons with the arc graduated as shown at G, the pins H acting as stops at either end for the indicating finger I. This pointer is not rigidly secured to the shaft J, but operates between two leather washers, the friction being sufficient to allow finger to revolve in unison with the shaft J, when pointer is in a position between the two pins. The travel of the indicating pointer will have a certain relation to the movement of that of the tool slide; the variation depending on the operating gears and the distance of the indicating point from the center of motion. After the fixture has been attached to the lathe, the arc is graduated. To do this, a 1/4 inch block is used. It is first placed between the cutting tools and the face of a shell held in the chuck, with the pointer I bearing against the right hand pin H. The 1/4 inch block is then removed and the tools advanced to the work; this causing the pointer to travel forward. When the tools are in contact with the face of the shell, the position of the pointer is marked on the arc of the piece F. By subdividing this distance, graduations can be made so that the calculations are very accurate. Suppose the distance travelled by the pointer should be 4 inches, for a 1/4 inch movement of the tool slide, this would be in the ratio of 16 to 1; therefore, each 1/4 inch graduation would represent a tool movement of 1-64 inch. On a 4.5 inch shell, this amount of stock on the base would correspond to a weight of one ounce. It will be readily apparent from the foregoing that the device will operate very accurately.

When operating, a shell is weighed and the amount to be removed (in ounces) is marked on the shell. After the shell has been secured in the chuck, the lathe is started and the tools advanced. When the tools come in contact with the work, the pointer is pushed against the right hand pin, and, as the stock is cut off, the pointer will advance along the graduated arc to the desired position. This arrangement has proven very satisfactory and highly efficient. Location of the shell in the chuck is not essential, as the device works independently and accurately for each shell operated on. Variation after facing does not exceed 1/4 of an ounce of the desired weight.

SELF LOCKING LIFTING TONGS

By J. H. R.

THE sketch herewith shows an inexpensive but serviceable lifting tong for 8 inch shell. In order to avoid the possibility of a shell slipping out of the tongs after it had been raised from the floor, it is very desirable that means be provided to lock it in a fixed position with a firm grip, as a knock in transit might dislodge it from the tongs. The rough bore of the forged claw is made quite free for the diameter of shell, and, through the central slot in the top the link is pivoted. When the horse-shoe claw is placed over the end of the shell and the weight raised, the action of the link will cause the tail end to press upon the upper portion of the shell body, thus holding it securely between the three points as shown. The simpleness of this device is one of its chief advantages.



SELF-LOCKING LIFTING TONGS.

MAKING HOLDEN-MORGAN THREAD MILLING CUTTERS

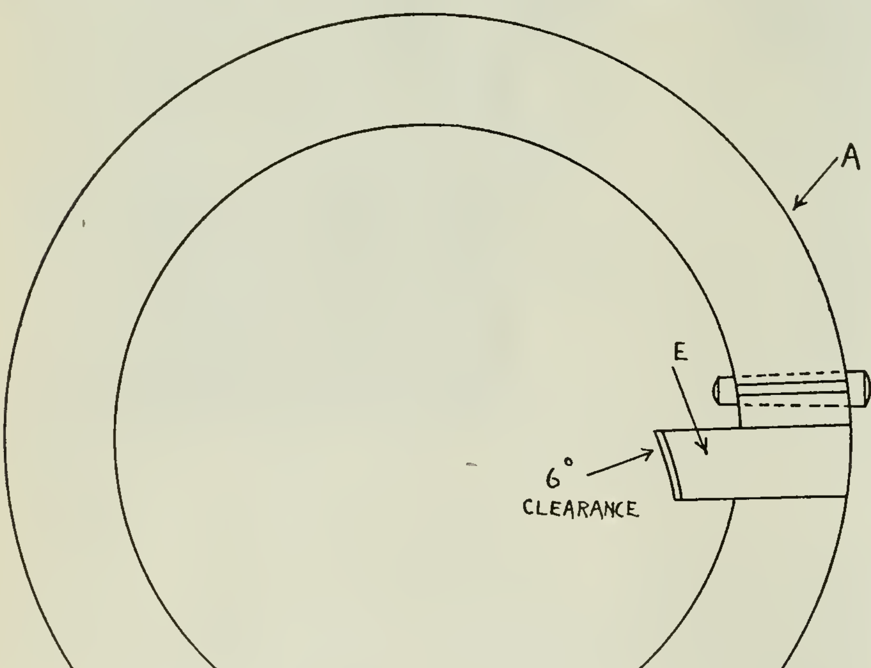
By Donald A. Baker

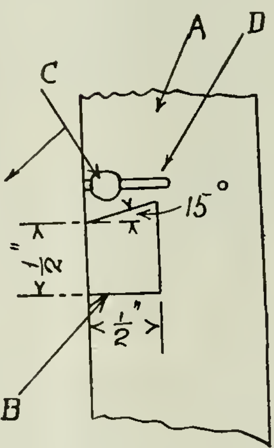
SOME time ago we found it impossible to get deliveries on thread milling cutters which we were using for cutting the base thread on time fuse bodies. These cutters are usually made up from a machine steel ring with carbon steel chasers welded on to the face of it. This of course was out of the question for us with our facilities so other means had to be devised to meet the emergency as described herewith.

First a machine steel ring A, was turned up to the correct size. In this ring was shaped and milled the slots represented by B, ten in number, to receive chasers. These latter were made of high speed steel and have been found to work much better than the carbon steel ones usually supplied by the makers. Alongside of each slot a hole was drilled and reamed to receive a taper pin C. After these were reamed, the ring was again set up in the miller and a saw slot put down through the center of each of the taper holes as shown by D. The object of this being that when the chasers, one of which is shown by E are put in place the taper pin C can be driven in and the metal of which the holding ring is made will be forced against the chaser thereby holding it in place.

Making the chasers was the most difficult and particular part of the work. Stock for these was cut off just long enough to make four chasers from a piece, this being a convenient length for holding in our milling machine vise. This stock was ⅝ in. square high speed steel. After milling to size on all edges it was cut to length for the chasers. Next a master hob was made for cutting the chasers. This was made up in the form of a milling cutter, being backed off in the lathe using the regular backing-off attachment. Next a simple jig was required for holding the chasers while they were being milled as of course it is absolutely essential that these be interchangeable to within very small limits. With the jig in place on the miller the chasers were milled one after the other. The chaser being fed up to the cutter, rather than the cutter being fed across the chasers, this being done to get a circular clearance back of the cutting edges rather than a straight clearance. This clearance was approximately six degrees.

It might further be stated that when trying out the first experimental cutter it was found that the hammer-like action of the chasers striking on the work was found to have a tendency to loosen up and drive back the chasers, some times leaving only one or two of the more solid ones to do all the work and thereby causing considerable chatter. To overcome this we have since made up our cutters, indicating the chasers with a dial indicator to make sure that they ran true, setting up in the grinder we have ground the back ends of each of the chaser teeth flush with the holding ring, then to back up and make sure that they could not drive back we turned up half inch thick machine steel rings and forced them on over the holding ring so that the chasers butted against them. Since then we have had no trouble and find that our home-made cutters will give as good results and much longer life, having high speed cutting edges, than the commercial ones.





ILLUSTRATING METHOD OF MAKING THREAD-MILLING CUTTERS.

INTERNAL CHUCKING DEVICES

By R. James.

CONCENTRICITY of wall thickness is one of the chief essentials in shell manufacture. The importance of this factor was impressed upon shell makers from the very beginning of that industry, and many methods have been devised to procure accomplishment. When roughing operations are being performed the necessity of accuracy is not so pronounced, as errors can be rectified on subsequent operations, but, when machining to finished dimensions, the chucking must be done in such a way as to reduce the eccentricity to the lowest possible degree. Owing to the small space that is permitted in which to grip the shells from the inner surface, the construction of the chucking device must receive the closest attention, both as regards design and operation, to provide accurate and positive manipulation. The stress that is placed upon these driving mediums, more especially on the heavier shells, is often very great, and, in addition to the driving feature, it is also important that the device should be rigid enough to withstand the torsional strain of the cut.

The sketches herewith illustrate two different types of internal chucks designed for and used on the 8-inch shell. The one shown in Fig. 1 is operated directly adjacent to the shell base, while that in Fig. 2 is operated by means of a hand wheel at the rear of the spindle. In Fig. 1, the expanding arbor A, has a tapered shank that fits into the nose of the lathe spindle; this arbor being secured in a permanent position by means of a dowel, not shown. The operating sleeve C has a notched collar, the outside diameter of which is turned a shade smaller than the finished size of the shell body to allow of the cutting tools passing entirely over the outer surface of the shell, without disturbing the operating sleeve. At three equi-distant points in the shell of the sleeves are cut slots to receive the hardened steel jaws D which are kept in contact with the uniform cam on the outer end of the expanding arbor by the action of the ring spring B. After the parts are assembled, they are retained in position by the small plate F secured to the face of the arbor. The design of these chucks is such as to increase the holding qualities should the shell develop a tendency to slip, under the pressure of the cut.

The action of the chuck shown in Fig. 2 is somewhat similar to that just described, but the design is much different. The operation of the expanding arbor is controlled by means of the hand wheel located at the rear end of the lathe spindle. Keyed to the end of the connecting rod A is the steel bush B, on the outer diameter of which are two notches H. The operating hand wheel C is bored out to fit the collar B, and is retained in a central position by means of two plates D, one on either side. The interior of this wheel is cored out to receive the two pawls E, these are placed in opposite directions, and pivoted on the pins F, being held to position by the action of the springs G. One of the pawls is used to tighten the chuck, while the other is for releasing; these operations being accomplished either by pressure or knocking. Secured to the nose of the lathe spindle I, is the piece J that takes the

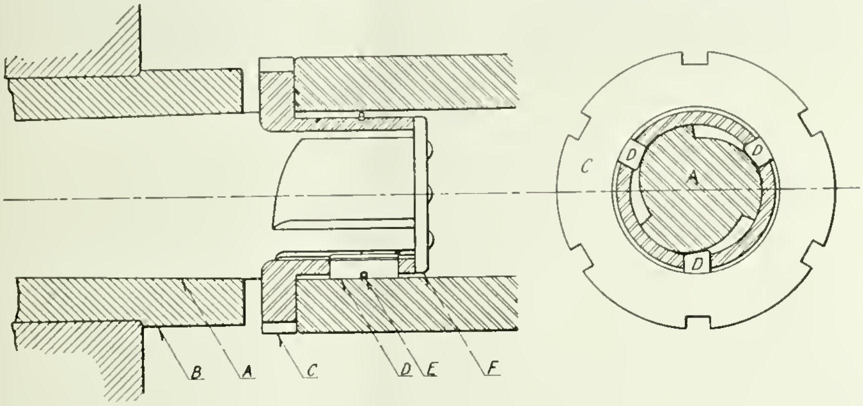


FIG. 1—EXPANDING ARBORS.

thrust of the shell and also the expanding jaws. The front end of the piece J is bored out and threaded to fit the operating bush K, which is firmly keyed to the end of the connecting rod. The outer end of the bush K has a short taper of 15 degrees which controls the expansion of the jaws M; these latter being held to position by the general practice of a ring spring. The jaws are of the sectional type and maintain a relative position to the operating bush K by means of the dowels N. The pitch of the thread on the bush is ¼-inch, and any slight slippage of the shell under the cut, will tend to further tighten the

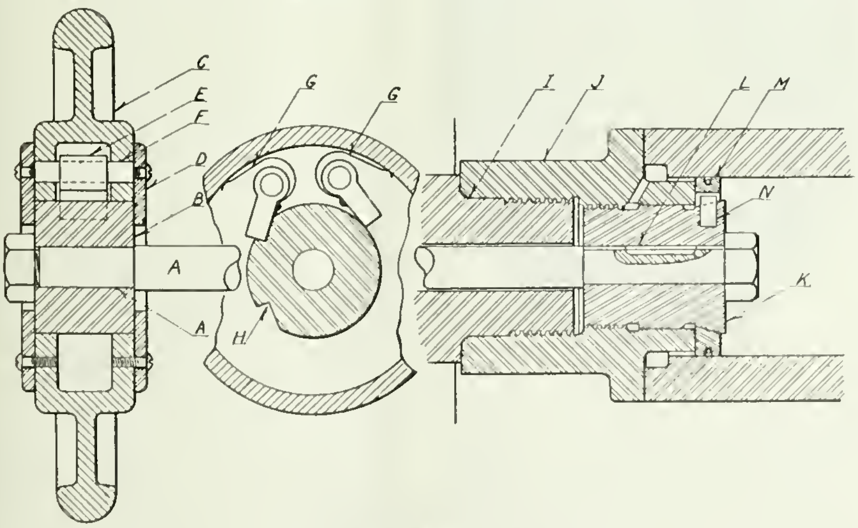

FIG. 2—EXPANDING ARBORS.

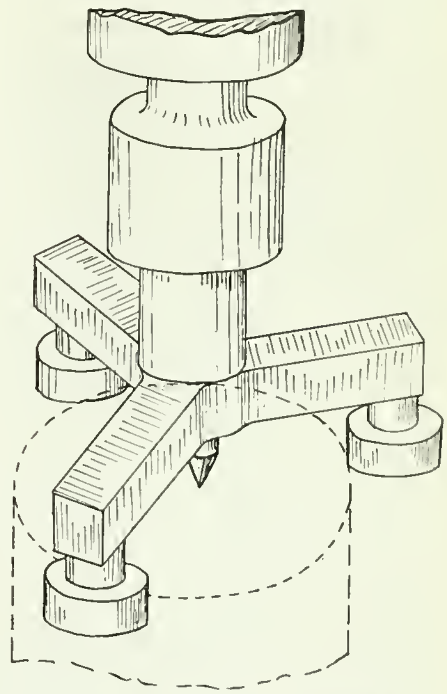
grip. In addition to the pressure that can be used to grip or release the chuck, the construction provides a handy means of jarring, by knocking the pawls E against their respective notches. To insure the accuracy of these chucks, narrow rings can be gripped in the jaws and tested for alignment so that any error can be easily detected and at once remedied.

RE-CENTERING DEVICE FOR SHELL BASES

By J. W. G.

THE device shown in the accompanying sketch has been used with complete success in re-centering adapters in large shells after they have been driven home tight. The centre is used for supporting the outer end during the grooving, waving and band turning operations, and must be perfectly concentric with the outer surface of the shell to insure the driving band being likewise. A sensitive drill was used for the job, the shell being held in a suitable chuck which positioned it from the outside.

Rollers are carried on a spider with two arms set 120 deg. apart, the radius being .010 to .015 in. less than the radius of a low limit shell so as to insure the centering tool being held over firmly in their direction. The tool is also set so that its cutting edge is midway between two rollers, the reaction on the edge plus the short radius causing the tool to re-machine the surface of the original centre so that it is truly concentric with the outside surface of the shell body. Care must be taken not to speed up the drill too much or irregular centres may result through the action of centrifugal force on the rollers. About 100 revs. per min. gave satisfactory results.



RE-CENTERING DEVICE FOR BASES OF 8-IN. SHELLS.

PLATE WELDS IN TENSION

A WELD in tension is always an indefinite quantity as regards resistance to rupture. If well made, its strength may approximate to that of the parts joined, but in most cases it is difficult to assign a definite value to the effective strength, as can be done in the case of riveted joints, and for this reason riveted joints are to be preferred wherever riveting is practicable. It is necessary that vessels with welded joints should have a higher factor of safety than those constructed with riveted joints, and where welding is adopted it is essential certain precautions should be followed.

In recent years, fusion welding by means of the electric arc and by the gas blow-pipe system has been largely used in constructional and repair work, while some makers of small vessels, for use in the storage of air and gas under pressure, have used one or the other of these systems of welding for the joints securing the different parts of the vessel together. Experience has shown that fusion alone cannot be trusted to unite the parts, and that hammering is indispensable to the formation of a reliable weld. In preparing the parts to be joined, their edges should be bevelled so that a V-shaped notch is formed at their junction. This should be filled bit by bit with the fused welding metal, and the parts hammered whilst at welding heat. If this is done there is a better chance of obtaining a sound and homogeneous weld.

PYROMETER DEVELOPMENT*

By Richard P. Brown**

AS FAR as we know the ancients who baked excellent bricks and forged iron in their crude way made use of a form of pyrometer used to-day with ever diminishing success—the eye.

The operation of the first mechanical pyrometers depended upon the difference in expansion of iron and brass. An iron tube containing a brass rod projected into a furnace, and these were mechanically connected to a multiplying movement which caused a pointer to pass around a dial. The difference in expansion of about ⅛-inch was sufficient to move the pointer up to 800 degs. Fah.

Siemen's Water Pyrometer

An instrument used quite largely 30 or 40 years ago was the Siemens water pyrometer. A copper ball weighing exactly 137 grams was placed on a piece of steel in the furnace, and after it had fully attained the temperature, it was quickly removed from the furnace and dropped into a vessel containing a thermometer and exactly one pint of clean water. The rise in temperature of the thermometer in the water could be read off in actual temperature degrees on a corresponding scale. The accuracy of this instrument necessarily depended upon exact measurement of the quantity of water in the vessel and the weight of the copper ball which scales away slowly under heat. The time taken to remove the ball from the furnace and drop it into the water must necessarily vary slightly. An accuracy within about 25 degs. Fah. was, however, usually attained with this instrument. The Siemens water pyrometer is still used by armor plate manufacturers as they can readily place a number of copper balls on a piece of armor plate which cannot be easily reached by more improved pyrometers. These instruments are in use in the armor plate department of the Bethlehem Steel Co., South Bethlehem, Pa.

Principle of Resistance Thermometers

The principle on which resistance thermometers operate is the change in resistance of metals due to change in temperature. A coil of platinum or pure nickel wire protected with a suitable tube is inserted at a point where the temperature is to be measured, and with a constant source of current passing through the coil of wire, the resistance increases or decreases, depending on the temperature. This change in resistance can be easily measured as an adjustable resistance is used to balance the resistance of the bulb, and a galvanometer shows when the balance is reached. The adjustable resistance with sliding contact arm can have a temperature scale for direct reading. This instrument is an exceedingly accurate one for measuring low temperatures, but is hardly to be recommended for high temperature service.

Thermo-Electric Methods

For measuring temperatures above 1,000 degs. Fah., the thermo-electric method has come to be by far the most largely used. A thermo-electric pyrometer consists of a thermo-couple, a measuring device, and wires connecting the thermo-couple and the measuring device. Experience has taught us that for measuring temperatures up to 200 degs. Fah. a thermo-couple of bismuth and antimony is best. For temperature to 1,000 degs. Fah., a satisfactory thermo-couple consists of one wire of iron the other 60 per cent. nickel and 40 per cent. copper. For the measurement of temperatures as high as 1,800 degs. Fah., a very satisfactory base metal thermo-couple consists of one wire of 90 per cent. nickel and 10 per cent. chromium, the other wire 98 per cent. nickel and 2 per cent. aluminum. The General Motors Co., Detroit, has developed a base consisting of silica, manganese, nickel and aluminum.

For a long time pyrometer builders attempted to duplicate the wire in order to procure thermo-couples which would reproduce the voltage of the previous thermo-couples, but this gave large amount of trouble and no great precision could be secured. Several years ago the policy was adopted of shunting each thermo-couple with manganin wire, reducing the voltage at the terminals of the thermo-couple about two millivolts. Each thermo-couple is adjusted in an electric furnace to a standard, and a maximum error of one-tenth of a millivolt or 4 degs. is permitted. In this way a thermo-couple as sent out produces a definite voltage within 4 degs. Fah. This method of shunting the thermo-couple also permits of the customer re-standardizing his instrument at intervals.

Wire Insulation

The wires forming a thermo-couple must be insulated from each other throughout their length. This insulation must withstand high temperature, must be a good insulator, and must withstand reasonably severe handling. A common method of insulating base metal thermo-couples is to wrap them with asbestos, and paint the asbestos winding with a solution of sodium silicate. Another method is to fit lava or porcelain beads over the thermo-couple wire. For the platinum thermo-couple the insulation must be of porcelain or high grade fire clay, free from impurities.

The life which will be obtained from any thermo-couple installed in a furnace will very largely depend on the protecting tube over the thermo-couple. For temperatures up to 1,200 degs. Fah., a high grade wrought iron tube gives satisfactory results. The life of this tube can be increased by calorizing, a process which impregnates the pipe with an aluminum oxide recently developed by the General Electric Co. This will increase the life of the pipe about three times where used at temperatures around 1,400 degs. Fah.

Compensating Box

Until a few years ago, no particular attention was given to caring for the source of error caused by changes in temperature at the cold junction of the thermo-couple. Recently, however, it has been customary to run compensating leads of the same material as the thermo-couple to a distant point, preferably under ground, where the temperature is uniform, instead of having the cold junction just outside the furnace wall, where it might vary several hundred degrees. Where it is not possible to place the cold junction in the ground, on account of the furnaces being on an upper floor of a building, a compensating box can be used. This device consists of a lamp and thermostat which will maintain the temperature constant within two degrees. These compensating boxes can be supplied to maintain the cold junction constant for any temperature from 50 to 150 degs. Fah. The temperature for which the compensating box is set must necessarily be higher than the atmospheric temperature of the room in which it is located.

Thermo-Couple Voltage Measurement

There are two distinct methods of measuring the voltage produced by a thermo-couple—the millivoltmeter method, and the potentiometer method. The millivoltmeter consists of a permanent magnet with its pole pieces, in the field of which a copper wound coil swings in jeweled bearings. Instruments of the millivoltmeter type were in extensive use commercially abroad, and to some extent here as long as 20 years ago, but the instruments were of such delicate construction as to be hardly suitable for general commercial use. Usually they were supplied with the moving coil hung between fine wire suspensions, and were easily broken through jars or handling in transit. These instruments were of high resistance, approximately 300 ohms.

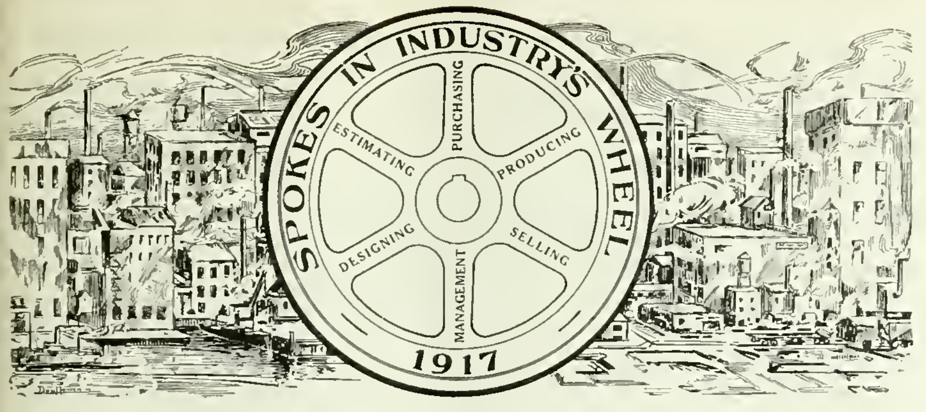
On account of the delicate construction of this type of imported instrument, a standard form of switchboard millivoltmeter, frequently used as an ammeter, came into extensive use about 1905, and is still in use. It has a resistance of about 5 ohms, and each individual instrument must be calibrated for a thermo-couple of a certain length and for use with leads or wiring of a definite length. Slight changes in resistance, due to changes in the length of the thermo-couple, or length of the wiring, naturally effect the indication, as the internal resistance of this type of millivoltmeter is so low.

In the potentiometer method of temporary measurement, the electromotive force produced by the thermo-couple is measured by opposing to it a known variable electro-motive force, usually that of a dry cell contained in the

(Continued on page 322.)

*From a paper before the Steel Treating Research Club, Detroit.

**President, the Brown Instrument Co., Philadelphia.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

E. T. SPIDY

JUST as in the development of Canada's agricultural and mineral resources, railroading in its myriad forms of activity has been almost wholly responsible during the last four decades for the growth and present day prominence of her industrial enterprise in its variety scope. Progress in railway building and rolling stock additions and betterment has been more or less consonant with manufacturing prosperity within our borders, and even with the possibilities of a shipbuilding industry of quite gigantic proportions being permanently established on our lake, river, and ocean shores, there is little doubt, in view of the vastness of our territorial domain, otherwise unredeemable, that railroad enterprise will still continue to contribute the major quota of opportunity for our future industrial and general commercial progress. Our "Spoke" this week is from a railroad driving wheel.

E Thomas Spidy, shop engineer, Winnipeg shops, Canadian Pacific Railway Co., was born March 18, 1887,at Brighton, England, his father being a native of Glasgow, Scotland, and his mother of Brighton, England. In 1889, the family went overseas to Melbourne, Australia, leaving the latter city after a two years sojourn and settling in New Zealand. In the town of Petone, near Wellington, a start was made in the procuring of an education for our youthful traveller. With the return of the family to England in 1897, however, other plans, and under, no doubt, more auspicious opportunities, had to be made to complete the education of our "Spoke," and that he actively co-operated in these is noticeable from the fact that a year later he won a Scholarship entitling him to free tuition, etc., at York Place Science School, also at Brighton Technical College, where he took the Mechanical Engineering Course.

From the latter part of the foregoing paragraph, it will be quite apparent that Master Spidy had a mechanical bent, hence his becoming apprenticed in 1903 at the Brighton Shops of the London, Brighton & South Coast Railway Co., will occasion little surprise. It was during this apprenticeship period that his Mechanical Engineering Course was completed, the Railway Co. co-operating toward that end by allowing all apprentices the necessary time for instruction, and otherwise encouraging them towards greater individual fitness in trade essentials.

In 1909, Mr. Spidy came to Canada,

E. T. SPIDY.

securing a position in the piecework department at the C.P.R. Angus Shops, Montreal. A perhaps fortuitous circumstance just then was the fact that H. L. Gantt, well known in matters pertaining to efficiency and system of industrial organizations, was reorganizing the piecework and schedule departments there; in any case, there is little doubt but that our "Spoke" was both an interested observer of the effects produced and a mental appropriator of the means employed and their method of application. In 1910 he was appointed to the position of Instruction Card Inspector at the Angus Shops, and a year later earned promotion as Assistant General Foreman in charge of efficiency works at the Toronto Shops of the C.P.R. During the same year—1911, he was transferred to the Company's Winnipeg Shop in the like capacity, being later promoted to the position of Shop Engineer, which is his present title.

Mr. Spidy married Miss A. M. Davies of Quebec City, in August 1913, the family consisting of one daughter 2½ years of age. His private address is 4 Rubin Apartments, Fort Rouge, Winnipeg, Man. He is a junior member, American Society of Mechanical Engineers, also a local associate member of the Canadian Society of Civil Engineers, being Secretary of the Mechanical Section, Winnipeg Branch of same. He is lecturer in Mechanical Engineering, University of Manitoba, having been appointed such in 1916; the subjects taught include Machine and Steam Power Plant Design.

"My experience" says our "Spoke," has been very varied, starting with time study work in various departments, leading on to the development of tools for better production; improving layouts of machinery; scheduling and routing locomotives and cars through the different departments of a railroad shop, operating a drawing office, and maintaining the machinery of all departments etc.; a series of activities contributing to a viewpoint, that while not new, may emphasize an old one—that the value of training cannot be overestimated. First in value is the practical training and secondly the theoretical training. I fully endorse the trade educational movements evident in our large cities, but strongly urge that the practical side be given more consideration. My experience is that in the interval between the time a student leaves college or school, and the time when he needs such higher education as calculus, he usually forgets it and has to use ordinary mathematics for his problems. Apart from the training effect, this represents time lost that might be applied with advantage to the practical side of various questions."

"One of the most effective methods of increasing output, is by comparison. The latter is possible only by knowing what the "other fellow" is doing. The engineering journals fulfil this need, both in the editorial and advertising sections. I have picked out many an idea from instructive advertisements, and while often have little time except to "go through" a journal, I always do this with the eye for something new, finally removing the selected articles and filing same.

"King George got a big fight on." In the region west of the Yukon, this message, given by Indians, was the first news of the war received by H. Collier, a trapper, who promptly returned to civilisation, and, in his own words, "joined up to get some good shooting."

GUIDANCE SPECIFICATION FOR TRIPLE-EXPANSION MARINE ENGINES FOR CARGO BOATS*

IN the present crisis of the country's history it is the duty of all of us to bethink ourselves and consider how we are to hold our own in the approaching contest for supremacy in the industrial world. As shipbuilders and engineers, it is specially incumbent on us to look forward to what is likely to happen after the war, and to prepare for the new conditions as far as we possibly can. Intensified and organized competition from abroad is the least that may be expected. As to whether this will be met or not depends on whether our manufacturers so bestir themselves as to procure not only vastly increased economy in production, but also increased efficiency of their products. Labor questions do not come within our present scope, and we therefore confine ourselves to the scientific and technical factors of the problem, the influence of which cannot well be over-rated. Old designs and easy-going or antiquated methods will be rigidly overhauled, and, where necessary, must be brought up to date under the guidance of the latest research and reliable experience.

Animated by these views, the Council of the Institution, after grave consideration, have taken the first step in what they trust may develop into a beneficial and helpful enterprise, and hereunder present for discussion by the members the draft of the Guidance Specification for Reciprocating Triple-expansion Engines intended for moderate-speed cargo boats engaged in general trade. The specification is based on the best practice of the day and the district, and the object in view is the ultimate standardization of parts. There is no intention whatever to change accepted and successful practice, but merely to reduce that practice to a common basis, and to add to it when desirable or necessary, in order to raise performance to the highest pitch of efficiency. It is hoped that ultimately the specification will be extended to include not only the main engine proportions and scantlings, but also the boilers, auxiliaries, and other details. Quadruple-expansion geared turbines, as well as internal combustion engines, will also be dealt with as time permits.

The Council suggest that the present instalment, as and when approved by the members in general meeting, shall be known as "The North-East Coast Institution Guidance Specification (1917) for Cargo Boat Triple-expansion Engines." It is hoped that it will be accepted by marine engine builders, and that it may prove beneficial, not only in securing maximum rate of progress in technical advance, but also in promoting convenience and despatch in the purely business sphere. The Council propose that discussion in the meantime be restricted to the subject matter of the present draft, and that an annual revision be made in order that the specification may be kept thoroughly up to date, and may command the confidence and promote the ultimate interests of all concerned.

Specification

1—Indicated Horse Power.—For calculation purposes in this specification and in average sea conditions the I.H.P. is to be found as follows:—

$$\text{I.H.P.} = \frac{D^2 S N}{700}$$

=diameter L.P. cylinder in inches.
S=stroke in feet.
N=revolutions per minute. Found as per Section (2).

The divisor is adjusted for a referred mean pressure of 30 lb. per square inch.

$$\text{2—Revolutions.—}N = \frac{32\,(S+4)}{S}$$

3—Boiler Pressure.—180 lbs. per square inch (gauge).

4—Ratios of Cylinder Areas—Ratio for 180 lb. pressure:—

H.P.	M.P.	L.P.
1	About 2.74	About 7.5
	1	" 2.74

5—Cuts Off at Sea Power:—

Per cent.	Per cent.	Per cent.
About 57.5	57.5	55

6—Speeds of Steam.—The mean steam speeds to be calculated as follows:—

$$\frac{\text{Area of cyl. in sq. in.} \times \text{piston speed in feet per sec.}}{\text{Area of pipe, port, or opening in sq. in.}} = \text{Speed in feet per sec.}$$

Table of mean steam speeds in feet per second:—

	H.P.	M.P.	L.P.
Main steam pipe ..	110	...	...
Port opening	110	150	240
Steam ports	80	85	100
Exhaust passage or pipe	60	65	75

Width of Steam Ports.—Width of ports to be about 0.8 of diameter of cylinder.

7—Maximum Load.—The maximum load on main working parts to be taken as the product of the area of H.P. cylinder in inches and the boiler pressure in pounds per sq. in. (gauge).

8.—Crank Shaft.—The diameter of crank shaft in body to be to nearest ⅛ in. above Lloyds Rule, and the proportions of the remaining parts to be not less than the following:—

(1)—Diameter of crank-pin to be equal to diameter of shaft.

(2)—Diameter of crank shaft in web to be equal to diameter of shaft plus ½ in.

(3)—Diameter of webs to be equal to diameter of crank pin by 1.85.

(4)—Thickness of webs to be equal to diameter of shaft by .62.

(5)—Thickness of couplings to be equal to diameter of shaft by .25.

(6)—Six coupling bolts to be used for shafts up to and including 15 in. diameter. Nine coupling bolts to be used for shafts above 15 in. diameter.

(7)—Diameter of pitch circle of coupling bolts to be 1.43 diameter of crank shaft.

(8)—Diameter of coupling bolts to be equal to:—

$$.7 \times \sqrt{\frac{\text{dia. of shaft}^3 \text{ in inches}}{\text{number of bolts} \times \text{dia. pitch circle in inches}}}$$

Bolts to be parallel.

9.—Length of Connecting-rods. — Length of connecting-rod between centres to be twice the stroke or four times the crank radius.

Diameter of Connecting-rod. — Connecting-rods may be made parallel, same diameter as piston-rod body.

Connecting-rod Top Ends.—Connecting-rods to have single top end gudgeons for all engines having H.P. cylinders of 25 in. diameter and under.

10.—Crosshead Guides.—Main crosshead guides to be of the single type in all sizes of engine.

Load on Main Crosshead Guides. — Maximum load in pounds on crosshead guides to be taken as:—

$$\frac{\text{Area of H.P. cyl. in sq. in.} \times \text{boiler pressure in pounds per sq. in (gauge)}}{4}$$

11.—Maximum Pressures on Principal Bearing Surfaces:—

	Lbs. per sq. in.
Main bearings	250
Crank pins	500
Crosshead gudgeons	1000
Guide shoes (ahead)	55
Guide shoes (astern)	110

Diameter by length to be taken as area of bearings.

Overall length by overall breadth as area of guide shoes.

12.—Maximum Stresses on Principal Working Parts:—

	Lbs. per sq. in.
Ingot steel piston rod at screw	6000
Piston-rod body (after deducting ¼ in. from diameter to allow for returning)	3000
Piston and connecting-rod bolts at screw	5500
Main bearing bolts	4500
Main bearing keeps (if forged)	6000
Connecting-rod bottom end keep (if forged)	7500
Piston-rod keep (if forged)	7500

(The keeps are calculated as beams with distributed load and supported ends.)

13.—Valve Gear. — The valve gear sizes to be determined from the load on the M.P. slide valve spindle, calculated as follows:—

Load in pounds = .165 [54 (A-B) — 9 C.],

Where A = area of face of M.P. valve
B = combined area of steam ports in valve face in sq. in.
C = combined area of exhaust ports in valve face in sq. in.

Valve Spindles.—Diameter of valve spindles at gland to be not less than:—

$$\frac{\text{Diameter of piston-rod at gland}}{2} + \tfrac{5}{8}\text{ in.}$$

*Compiled by the Council and Members of the North-East Coast Institution of Engineers and Shipbuilders, 1917.

Maximum Pressures on Bearing Surfaces of Valve Gears:—

	Lbs. per sq. in.
Link block gudgeon	500..
Link block slippers	300
Eccentric rod top end pins..	500
Eccentric sheaves (ahead and astern)	85

14.—Thrust Block.—When of horseshoe type, the pressure on thrust collars not to exceed 70 lb. per square inch when calculated from indicated thrust, which is determined as follows:—

$$\text{Lbs. Indicated thrust} = \frac{\text{I.H.P.} \times 33{,}000}{\text{Pitch in feet} \times \text{revs. per min.}}$$

15.— Circulating Water.—The amount of circulating water supplied to be 40 times the feed, taking the latter at 15 lb. of steam per I.H.P. per hour.

16.—Main Engine-driven Reciprocating Circulating Pump (Double-acting).—To be proportioned to deliver the above quantity of water at a displacement efficiency of 80 per cent

17.—Maximum Speeds of Circulating Water.—The speeds of circulating water are to be calculated as follows:—

$$\frac{.8 \text{ area of bucket in sq. in x bucket speed in feet per sec.}}{\text{Area of passage in square inches}} = \text{Speed of water.}$$

Approximate Speeds in Feet per Second

	Feet per second.
Main injection...............	9.0
Passages in pump...........	5.0
Valve grids..................	6.0
Past lift of valves............	9.5
Discharge pipe...............	7.5

18.—Air Pump.—Capacity of air pump not les than one-sixteenth of the capacity of L. P. cylinder.

19.—Main Engine-driven Feed Pumps. Capacity each engine-driven feed pump 1-700th of capacity of L P. cylinder.

20.—Pump Gear.— Load on pump gear to be calculated as follows:—Load in pounds = 25 (area of air pump bucket + area of circulating pump bucket) + 15 (area of both feed pump rams + area of both bilge pump rams). All in sq. in.

Maximum Pressures on Pump Gear Bearing Surfaces.

	Pounds per sq. in.
Pump link pins..............	400
Engine link pins...............	300
Pump lever centre gudgeon bearings	250

For cargo vesels of large tonnage it is recommended that the circulating and feed pumps be independently driven pumps.

21.—Utilisation of Heat in Exhaust Steam from Auxiliary Engines.—A source of very considerable economy in a marine installation being the complete absorption by the feed water of the heat in the exhaust steam from the various auxiliaries including the steering engine electric light engine, and evaporator, such a vacuum should be carried in the main condenser as will enable this to be effected in all seas in which the vessel trades. A vacuum of 27in., maintained in the steam space of the condenser, the temperature of the sea being 70 deg. Fah. (barometer 30in.), has been found to meet these requirements on an average cargo boat.

22.—Cooling Surface.— In determining the amount of cooling surface per I. H. P. average at sea, provision should be made for the rapid initial degrading effect of oil and scale on the tube surfaces, and also for the permanent prejudicial effect on the condensing efficiency of the residual air in the condenser

23.—Air Extraction by Steam Jet.—When a steam jet is employed for the extraction of air, and a suitable design of condenser is adopted, the greatly increased efficiency of the condensing surface enables a higher temperature of feed to be obtained, and for a given vacuum the sizes of air pump and circulating pump, to be considerably reduced, thereby saving pumping power and total weight.

24.—Pressure Losses in Vacuum System.—It is important to minimise the loss in absolute pressure between the steam space in the condenser and the mean vacuum line as shown on the L. P. indicator diagram, and also the loss between the steam space in the condenser and the air pump suction pipe.

In good practice (a) the vacuum line should scale 12¼lb., per sq. in. below the atmospheric line when the vacuum in the steam space of the condenser is 27in.,(b) the speed of steam over the condensing surface should be such that the total resistance through the condenser does not exceed one-tenth of an inch of mecury or 1.36 in. of water, as measured by a resistance guage.

25.—Prevention of Delivery of Oil to Boilers.—It is desirable that the oil should be separated from the auxiliary exhaust steam before it is used to heat the feed-water, but in any case the feed water must be passed through a satisfactory filter before delivery to boilers.

26.—De-aeration of Feed-water.—Means should be provided for the deaeration of feed-water before it enters the boiler, with the object of preventing corrosion.

27.—Prevention of Heat Loss by Lagging.—Heat loss by radiation from unprotected surfaces being a very appreciable factor in the ultimate economy of a steam installation, the lagging of boilers, steam pipes, cylinders, auxiliary exhaust pipes, and feed pipes should receive expert attention in order to promote efficiency by means of an adequate thickness of non-conducting material applied in a workmanlike manner.

ONTARIO NICKEL DEPOSITS

THE report of the Province of Ontario Royal Commission on nickel was brought down in the House on March 26. It is a complete history of the nickel industry done up in a neat volume of 600 pages. Its cost is estimated at $60,000. It tells of the difficulties to be overcome before the metal could be refined in Canada, and of the triumph of science over sulphur fumes. The amount of nickel in sight in Ontario is given as about 70 million tons, but it is estimated that the total deposits amount to about double tha amount.

Taxation of minerals is discussed at length, but a hasty examination of the volume does not reveal any concrete recommendation as to what the Ontario tax should be. The evidence taken before the commission is given in an appendix. Through the report runs a seam of warning as to the dangers of confiscation, and of the evils that may arise should capital be intimidated.

The only reference to Ontario nickel reaching the Germans is contained in a short paragraph which deals with conferences held with the Imperial Government. The only comment is that for obvious reasons these conferences were secret, and what transpired could not be divulged.

ONTARIO GOVERNMENT ESTIMATES

FURTHER supplementary estimates totalling $1,468,000 were tabled in the Legislature on Monday. Of this amount $218,706 represents grants for colonization road construction in Northern Ontario and a further $161,731 expenditures to be made on general public works, roads, bridges, etc., in the North.

Accompanying the supplementary estimates is an estimate of capital expenditure proposed for the T. and N. O. and the Hydro-Electric Commission. The commission plans to spend $6,928,790. Of this $1,000,000 is for work upon the Niagara power development, $2,360,000 on Niagara transformer stations, $985,000 on Niagara system steel tower lines and $1,695,000 for Niagara system extensions. There are also substantial estimates for extensions of the Severn, St. Lawrence, Eugenia and Muskoka systems.

The T. and N.O. plans to spend $876,000, of which $250,000 is for 100 new freight cars to replace those burned, $100,000 for the erection of steel bridges in place of timber bridges $125,000 for the extension of the Kirkland Lake branch and $143,000 for general construction work. The T. and N.O. and Hydro estimates bring the total presented yesterday to $7,805,383.

Cooling Electrical Machinery.—In the cooling of electrical machinery, with the high speed units of large output, the designer is seriously handicapped, says the *Electrician*. As turbo-alternators go in these days, the 15,000 kilovolt-ampere alternator is a machine of medium size. In such a machine the total loss is about 545 kilowatts, and an enormous volume of cooling air is required for carrying away the heat due to this loss. According to B. G. Lamme, a simple approximate rule for determining the quantity of cooling air required is that an expenditure of one kilowatt in one minute will raise the temperature of 100 cubic feet of air 18 deg. cent. Therefore, for a temperature rise of the outgoing air of 20 deg. Cent. above that of the incoming air, a loss of 545 kilowatts will necessitate a supply of ventilating air of approximately 50,000 cubic feet per minute.

POWER AND ITS GENERATION

Power, However Generated, and Ultimately Transmitted, is a Prime Essential of Manufacturing Enterprise. The Discussion of its Cost Side is this Departmental Objective

STEAM POWER ECONOMICS*

By C. E. Stromeyer.

THE present war, with its accompanying high prices and the possibility of a trade war after the conclusion of peace, has naturally directed attention to many economic questions, including those relating to steam boilers.

Discussions about the difference between English and German economic systems of operating factories have revealed that abroad great harmony exists between the State and manufacturers, and, as a consequence, German works have adopted systems which commend themselves because of their leading to national economy. Our customs seem to force individual works to think more of themselves than of the country's welfare. Here we need only concern ourselves with the fuel question which is briefly as follows: Our manufacturers have been spoilt by the ease with which they could obtain the very best coal in the world. When new labor-saving appliances were invented which, while increasing the output, also increased the power required to drive them, the manufacturers filled their works with them and overworked their boilers; and as this could only be done with the best of coal, slack was for long periods a drug in the market.

Wasted Coal Percentage

Constant improvements in mechanical stokers have effected a change, but no overworked boiler can burn dirty coal, no matter whether it be fed by hand or by mechanical means, and slowly but surely colliery owners found that it did not pay to bring inferior qualities of coal to the surface. As most coal seams consist of several layers, of which some are rich and others poor, the poorer layers of worked seams are often left underground and buried for ever, because to mix them with the richer ones would disproportionately lower their value.

According to recent statements by coal experts, this wasted coal amounts to 25 per cent. of the output. This national waste is due largely to our almost universal practice of overworking boilers. Bunker coal for steamers must, of course, be as free as possible from mineral matter, and export coal has also to be reasonably pure, but there is no reason, except want of boiler power in our factories, why inferior coal should not be burnt wherever it can be got. It is done on the Continent of Europe, because first-class coal cannot be obtained, but there the works provide themselves with ample boiler power, and on the whole they obtain a higher efficiency than we can hope for with our superior coal but hard-worked boilers.

Coke as Fuel

Somewhat similar remarks might be made about the burning of coke. It is a by-product of the gas works of towns, and might with gas be a valuable by-product of works which would make it their business to produce sulphate of ammonia and the volatile oils of distillation. Coke ought, therefore, to be a cheap fuel. At present, however, its production is limited, and those consumers who are compelled to use it as a fuel can be made to pay so heavy a price for it, that the profits can be used for relieving the rates. Steam users naturally do not like coke, partly on account of its relatively high price and partly because it would require larger boilers than the present ones in which to burn it with as good effect as the best coal. Thus, here again, our habit of getting the highest possible duty out of our boilers may be looked upon as being one of the causes, though perhaps only a secondary one, which hamper our coal-tar industry.

Our present practice may possibly be more profitable to the individual factories and collieries than to those of the Continent of Europe, though this is a moot point, but there can be no doubt that this practice is very wasteful of our national coal resources, and it is to be hoped that after the war encouragement will be held out to those who, without loss to themselves, will assist at national economy.

Take the simple case of a shipowner who has to decide for what speed a ship, which he contemplates ordering, should be designed. He knows that with a low speed his ship cannot command paying freights, and, going to the other extreme, he also knows that if he fills his ship with engines and boilers, there will be no room for cargo, and his coal bill will be far in excess of his earnings. He will, therefore, have to decide on a medium speed which here may be assumed to be 10 or 11 knots. With the faster ship he will be able to make 10 per cent. more voyages than with the slower one, but his annual coal bill will be increased 20 per cent. and his carrying capacity slightly decreased, on account of the extra 20 per cent. of engine, boiler, and bunker capacity. Leaning on past experiences he may be able to say to himself that his prospective earnings would be about the same, no matter whether he were to decide on the 10 or the 11-knot boat. At this point national economic considerations ought to influence him, and he ought to say to himself: The 11-knot boat will carry 10 per cent. more cargo than the 10-knot boat, but it will burn 20 per cent. more coal. My profit will be the same with either speed; therefore, in order to assist my country in saving coal, I will decide to have the slower boat.

The factory owner is faced with other, but similar, problems, and will find that he too can make selections amongst a number of alternatives of which he should choose the one which, while it does not affect his profits, will be of economic advantage to the nation. It will be my endeavor to review these several alternatives.

Fuel Cost Contributories

The cost of fuel depends, of course, on the cost of labor, and that depends on the average cost of living. This will necessarily be increased after the war on account of the heavy taxation to which we as a nation will be subjected; but it is impossible to make even the vaguest guess as to the extent to which future prices of fuel will be affected by the increase in cost of fuel which may occur. We may assume that the coal consumption for a first-class modern steam engine can be reduced nearly down to one pound of coal per indicated horse power, or nearly 4 tons per year continuous working. In most factories only about one-third of the full time is worked, whereas the interest on capital is a continuous charge, and the total cost, including wear and tear, was in one modern factory found to be $60 per indicated horse power per annum, at a time when the cost of fuel was $3 per ton. Had the factory been working night and day the cost would have been $30 per indicated horse power per annum.

This compares very unfavorably with $8.50 to $12.15 per electric horse power, which is approximately the cost of continuous power production in some parts of Sweden, Norway, and on the slopes of the Alps. These districts are rapidly realizing that they can control enormous powers, and when these have been harnessed they are sure to attract to themselves many of our industries. After the war, wages now ruling are likely to be at least maintained, and the disproportion is likely to be increased. Then also, as the United States is not going to burden herself with additional taxes, the cost of living will not be increased there. The most threatening possibility, however, is that Prussia, true to her national traditions, not to be saddled with a national debt (her present one of 600 millions being merely an industrial one created when the State acquired all the railways), may repudiate all her internal war loans, and after a few years of severe personal hardship the taxation in Prussia, and consequently the average cost of living, and with it the price of labor and of coal, will be as low as before the war.

*From annual report of Manchester Steam Users Association; of which Mr. Stromeyer is Chief Engineer.

Record of Engine Performances

We may, therefore, expect that some time after the war, our cost of creating power for industrial purposes will be greater than in other countries, so that even without considering the question of economizing our national coal resources, it will be necessary for individual works to practise extreme economy as regards coal consumption.

In order to be able to reach a reliable starting point as to possible fuel economies, I have prepared the following list of engine performances. This is merely a repetition of the work which was done quarterly during the infancy of the Manchester Steam Users' Association, for at that time it was the custom to collect and publish information about the engine performances of our members. There seems to have been a greater willingness in those days than now to let us have the desired details, for although our membership has enormously increased since then, the present list is much smaller and less comprehensive than our earlier ones.

The majority of the recorded results are from spinning mills, and these have been classified according to the type of engines used, viz., low and high pressure compound, compound using superheated steam, and to triple expansion engines. The original returns embody the amounts of coal used for non-power purposes. In those mills where a separate boiler, usually a low-pressure one, was used for burning this coal, the return may have been fairly correct, but other returns are mere guesswork. However, by combining the most reliable of the available cases, the average fuel consumed in spinning mills for non-power purposes was found to be about 0.6-lb. per indicated horse power. In ring spinning mills the quantity is probably only 0.5-lb., partly because much of this power is converted into heat, which helps to warm the rooms.

Spinning Mill Power

The deductions which can be drawn from that part of the table which deals with the cotton spinning mills are, roughly speaking, that compound engines using steam of 100 lbs. pressure consume about 3.0 lbs. of coal per indicated horse power. For high-pressure compound engines, the net consumption is about 2.15 lbs. of coal per indicated horse power, and for triple-expansion high-pressure engines it is about 1.65 lbs. of coal per indicated horse power. The few compound engines which use superheated steam do not show up as well as might have been expected, but with one exception these engines are of an old type.

These results are neither as good as the results promised by engine builders nor as those attained during trials. This is but natural and should not be allowed to influence intending purchasers, for it must be remembered that a factory engine stands idle for two-thirds of its time, and that the raising of steam and the banking up of fires costs much fuel, say, 0.3 lb. per indicated horse power. If we make this further deduction we arrive at the following average net consumptions per indicated horse powers under ordinary working conditions, which are, of course, never as favorable as trial conditions, at which the makers attend and try to minimize all losses.

Old compound engines working with about 100 lbs. pressure consume about 2.70 lbs.

TABLE II. DATA FROM MISCELLANEOUS INDUSTRIAL PLANTS OF 300 I.H.P. AND OVER.

High-pressure compound engines consume about 1.85 lbs.

High-pressure compound engines with superheated steam consume about 1.45 lbs.

Tripe-expansion engines consume about 1.33 lbs.

Several cases in the table show how disadvantageous it is to use engines which are either too small or too large for the power produced by them, and one case demonstrates the advantage of speeding up an engine, but this remedy has its limits. No. 16 was tested with only the main and countershafting running, and showed that only about 75 per cent. of the indicated horse power reaches the spindles.

Weaving Mill Power

The information gathered from weaving mills is very unsatisfactory, for the average returns for heating and slashing, which ought to be very much more than spinning, are only about 0.8-lb. per indicated horse power; or if we deduct 3.0 lbs. net, as found for low-pressure compound engines of spinning mills, from the gross power of similar engines in weaving sheds, the coal used for heating and slashing seems to be only 0.4 lb., which is 0.2 lb. less than for heating alone. This discrepancy may be due in part to the fact that weaving sheds are flat structures and, therefore, not cooled as much by cold winds as are the high-built cotton mills. Possibly, too, the relatively heavy coal bills for power, heating, and slashing, tend towards rigid economy in the engine and boiler departments. On account of these uncertainties the following single case of a spinning and weaving mill may prove of interest, for here the heating was done by separate boilers.

Very careful records have been kept for a full year and the results work out at 1.36 lbs. of coal per indicated horse power, for power alone, and 1.23 lbs. for heating, slashing, and washing; deducting 0.6 lb. for heating, the slashing and washing process in this mill costs 0.63 lb. These works make fancy cloths—these include thick materials, for which the spinning and weaving powers are less than the average cloths, and for which the water to be evaporated in the slashing process is a maximum.

The above works produced their own electricity by means of a turbine. In some parts of the mill each loom has its own motor, in other parts a large motor is attached to the countershafts. Here the losses will be about 8 per cent. for the motor, and 15 per cent. for the countershafts, and then there will be about 10 per cent. loss between the turbine and the switchboard. The efficiency of this part of the works will, therefore, be $90 \times 0.85 \times 0.92 = 66.5$ per cent. The small driven motors on the looms will have an efficiency of about 10 per cent., so that the efficiency will be about $90 \times 0.9 = 81$ per cent. The mean efficiency for the whole mill will, therefore, be about 74 per cent. This is practically the same efficiency as determined for mill No. 16 in the table. Electricity measured at the switchboard is practically the same as brake horse power and, therefore, an electric unit is equal to about 1.5 indicated horse power.

Flour Mill Power

The tabulated results for flour mills are too few for the obtaining of average results, but the saving effected in the case of mill No. 36 is very gratifying. The data are of importance to those whose engines are of an old type, and, therefore, likely to be inefficient, because it will give some indication as to whether advantages are likely to be gained by renewing the installations on midern lines. Of course, each case must be judged on its merits.

Now it is evident from the above table that, as a rule, only about 1 lb. or 2 lbs. of coal per indicated horse power, or, say, $5 to $15 per annum, is likely to be saved by modernizing an old power plant. If, in addition, arrangements were to be made, by providing ample boiler power, for burning a cheaper quality of coal, a very great monetary saving might be effected, but unless collieries will provide inferior fuel to individual works, this desirable policy can only be carried out by large combinations of power producers.

Production and Transmission of Power

The Newcastle Electric Supply Co. has in a way shown what can be done in this direction, and their work has also revealed the difficulties which would have to be overcome in other districts than their own before success can be obtained. Their leading idea seems to have been to provide trunk wires which would do for power what railways do for goods. They provide collieries and ironworks with outlets for any power which may be produced from their waste coal and from the waste heat of their furnaces, and they thus provide the means for the sale of this power which would otherwise be wasted. This company has in some respects been favored by local conditions, but it had also to contend with serious difficulties which are even more serious in other districts. It had the advantage of promises from all the large works on the Tyne to buy power from them, and its first power stations could, therefore, be designed to work with large units and with a minimum of cost. Subsequently the North-Eastern Railway Co. agreed to purchase all its power for local traffic.

On the other hand, the Board of Trade limit on the voltage in the trunk wires made these connecting links very expensive, and as nearly every old power station had its own voltage and its own frequency of phase, practically every amalgamation necessitated the erection of entirely new installations. An initial difficulty, which has however been nearly overcome, was that the numerous corporations had the right to exclude outsiders from supplying their little districts with power; but they have seen the advantage of adapting their voltages and frequencies of phase to those of the company, and now they buy their electric power from it for the purpose of distributing it amongst their customers.

As far as can be ascertained, the charge per unit of electricity, if used all the year round without a break, has been reduced to about $22.50 per electric horse power. For eight-hourly supply, the charge would, of course, be much heavier, possibly as heavy as the cost of individual power production by a modern steam engine.

One reason why power can be produced thus cheaply is that the company with its network of transmitting wires can deal with collieries on the following lines: Each colliery can bring, or brings to bank some very dirty coal or shale, which is absolutely unsaleable. Of this fuel about 25 per cent. can be burnt in the colliery boilers, but the remainder is thrown on waste heaps and is occasionally burnt there. Now, the company, by installing a power station with ample boiler power close to the collieries, could consume all this apparently valueless fuel and produce four times as much power as was needed by the colliery. The colliery buys its quarter share and the rest is carried away in the trunk wires.

Ironworks are utilized in the same way. The heat wasted by the gases which escape from blast and other furnaces is far in excess of the power requirements, and was largely wasted, because without a trunk system to carry away the surplus power it could not be used. Now all this waste power is bought at a cheap rate and distributed.

In other industrial districts the conditions for conveying and selling power are rather unfavorable. The numerous corporations still exclude outside producers from within their boundaries, nor will they buy from outsiders, and they have not the necessary powers for building power stations outside their own districts, and thus utilizing the waste fuel of collieries. To produce cheap power from fuel, which has had to be carted to their own works, is out of the question. They also have not the necessary powers for supplying outsiders, and are, therefore, in the most unfavorable position for acting as power brokers or intermediary for the buying and selling of power. What makes matters worse is that nearly every corporation has its own particular voltage and phase, so that it could not, even if it would, buy and sell power from and to others.

This condition of things is not likely to change until factory owners learn that, with a proper system, they could easily be supplied with power at a cheaper rate than that at which they can produce it.

Gas From Coal

Another means of distributing power and economizing our coal resources is to convert coal into gas, distribute it in pipes and sell the by-products, thus encouraging agriculture and the coal tar industry. In a certain sense our corporations work on these lines, and even produce a third by-product—coke. The production and sale of coke might be encouraged more than it is, because it is a smokeless fuel; but here again we find the same conflicts as in the electrical field: corporation gas is too costly for cheap heating and power production, and producers of power gas are practically prohibited from introducing their pipes into towns.

It might be possible to combine the gas and electricity systems, then gas and its by-products could be produced from waste coal, and this gas could be used in internal combustion engines, to produce electricity. Unfortunately, however, the gas engine is not as reliable as might be wished, and it is also disliked because of the irregularities of its revolutions which cause flickering of lights and troubles in spinning mills. We have, therefore, to wait, but possibly not for long, for the perfection of the internal combustion turbine. At present the steam turbine seems to combine the greatest number of advantages; not only is its running very steady, but new designs are reported to be very economical.

The fuel economy question may, therefore, be briefly summarized by saying that hardly any improvement is likely to be effected in the economic working of boilers, for, as is well known, there is only a margin of about 20 to 25 per cent. to play with. Considerable pecuniary saving might often be effected by increasing the number of boilers, so as to be able to burn a poor and relatively cheap fuel if this can be got. For instance if, when best coal costs $5, dirty coal of, say, 75 per cent. heating value were obtainable for, say, $1.50 per ton, the coal bill would be reduced to one-half, but only if the local colliery can bring this dirty coal to bank and if the boilers are large enough to burn it.

Prime Mover Development

Our chief hopes will, therefore, have to be centred on engine improvements, for here large savings might be possible, because at present about eight units are thrown away for every one doing useful work. Improvements have been and still are being effected by inventors, and research workers have little scope for their activity. Research workers have already indicated very clearly that the internal combustion engine can attain a much higher efficiency than the steam engine, but the high cost of the fuel, either oil or gas, nearly balances this advantage, and constant engine troubles and repairs are both annoying and costly. Research workers have also shown that the turbine should be much more efficient than the reciprocating engine, but it is only comparatively recently that the efficiency of the steam turbine has equalled and slightly surpassed that of its older rival, and we look to inventors, rather than researchers, to reduce the remaining losses to a minimum, for the most convenient form of extracting power from coal is still the old method of burning it under a boiler. Central power stations are not limited in their choice to the steam engine for power production, and in view of the very high theoretical efficiency of internal combustion engines they very likely hope to see the internal combustion turbine brought to perfection.

From a national economic point of view, the combination of the internal combustion engine with electric distribution of power would seem an ideal one. Our collieries would then be encouraged to mine even our dirtiest coal. This coal would produce by-products for farmers and for the coal tar industries, and supply the engines with suitable gas, and our factories would receive their power at a lower cost than they could produce it.

BRITISH SPECIFICATIONS IN FOREIGN LANGUAGES

THE British Standards Committee, with a view to assisting the maintenance and extension of British trade after the war, has determined to translate its specifications in to French, Spanish and Russian, to give metric equivalents of English measures and to issue the specifications at a much lower price than has hitherto been possible. This fact was incorporated at the annual report of the Council of the Institution of Mechanical Engineers, which held its seventieth annual general meeting in London, Feb. 16. Arrangements are being made to establish local committees in the colonies and in foreign countries to obtain information and facilitate commercial transactions. The institution has appropriated a sum of $2,500 as a donation to the fund for this purpose. Michael Longridge was elected president to succeed Dr. W. C. Unwin, who has been president for the last two years. Dugald Clerk, Sir Robert Hadfield and Mark Robinson were elected vice-presidents.

CANADIAN NICKEL EXPORTS

FIGURES showing that Canada's exports of nickel in the fiscal year ended March 31, 1916, amounted to 70,443,000 pounds, valued at $7,714,769, are contained in the report of the Department of Trade and Commerce, Ottawa just issued. Of this total 11,610,000 pounds, valued at $1,779,801, went to Great Britain, and 58,832,000 pounds, valued at $5,943,969, went to the United States.

From the figures it would appear that in the fiscal years ended March 31, 1912, and March 31, 1913, no Canadian nickel was exported to Germany. In the fiscal year which ended on March 31, 1914, that is to say, a year before the war began Germany received 108,138 pounds of Canadian nickel ore or mattee. In the following year, ended March 31, 1915, again Germany received 179,354 pounds, valued at $22,866. Then the measures taken to prevent Canadian nickel reaching Germany took effect and from that date onward not a pound was exported to that country.

Training the Juniors.—The New South Wales Minister of Education has stated that his department should supervise and ensure the compulsory apprenticing of youths to some regular trade or calling before they are severed completely from their school life, in order to prevent the drifting of thousands of lads into unskilled occupations.

DEVELOPMENT OF STEEL CASTINGS MANUFACTURE

AT a recent meeting of the Manchester Association of Engineers, the first part of a paper—on the "Development of the Manufacture of Steel Castings," was read by Ernest F. Lange, M.I. Mech.E., A.M.Inst. C.E. A two-section sub-division was made, namely—1, Crucible steel processes, and 2. Bessemer steel processes. In the first, the author traced the history of the crucible processes of manufacture from Reaumur's early writings and experiments up to the present, dealing incidentally with Huntsman's discovery of cast steel, the Siemens regenerative crucible steel furnace, "Mitis" steel castings, the modern coke-fired furnace, and Krupp's steel foundry. In the second section the author traced the development of the Bessemer steel processes. The Walrand and Robert converters were described, and the author compared the features of the former with the Tropenas converter, which to-day is the most extensively used.

Referring to the Walrand-Légenisel process, it was stated that the most important claim on its behalf was that it enabled the production of hot fluid metal to be achieved on a smaller scale than any known method, other than by crucibles. It was mentioned in this respect that there is in use in Paris a ½-ton converter giving a perfectly hot fluid steel with the Walrand method of ferro-silicon superheating. The author concluded this section of the paper with a description of the Stock oil-fired converter. He said that in no country had the small converter process for the manufacture of steel castings had a greater development than in Belgium, although at first glance there were no obvious reasons why that should be so. The fact remained that, before the war, the Belgian foundries were able to import hematite from Great Britain, convert it into steel castings, and undersell the British foundries in their own markets.

As a result of careful study of the Belgian steel casting industry, by personal observation and inquiries in that country itself, Mr. Lange came to the following conclusions as regards the causes that led to its success:

1—The excellent organization and equipment of the steel foundries.

2—The suitability of the small converter for making small and medium weight castings, as shown by the fact that the output of steel castings in Belgium has quadrupled itself in the last twelve years.

3—The advantage of no artificial restraint of the production on the part of the trade unions, i.e., the advantage of working piecework instead of day work.

4—The fact that small converter castings require smaller casting heads and runners than with the open-hearth process.

5—The castings require less annealing.

6—The Belgians have an abundance of cheap natural moulding sand, particularly suitable for the small converter process.

PROCESSES IN MANUFACTURE

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

COATING IRON AND STEEL WITH ZINC-GALVANIZING—I.*

By W. Ellison Sharples, M.I.S.I.

THE object of this paper is to deal with the subject of coating iron and steel with zinc or, as more generally termed in the commercial world, galvanizing. Owing to the great conflict waging in Europe this industry, from a purely commercial point of view, has been considerably curtailed. In normal times it is a large and extremely important industry. In the last generation the galvanized iron trade has developed enormously. There is no doubt that zinc is the best rust preventative for iron and steel, but it is not altogether on account of its cheapness that it is so extensively used, as there are other metals which are cheaper and less corrosive than zinc. If zinc did not corrode it would be useless for the purpose for which it is used.

When iron or steel, having been coated with zinc, is exposed to the atmosphere, a galvanic action is set up, although extremely slight. Any two dissimilar metals form a galvanic couple, but zinc being "electro-positive," the zinc suffers corrosion at the expense of the iron, which is the "electro-negative" metal. The effect is that, providing there is any zinc left upon the iron, the corrosion goes on exclusively with the zinc, the iron or steel not being corroded at all.

The oldest galvanizing process and the one most generally used is the hot or dipping process. The cold or electro and the Sherardizing processes are also used to a considerable extent, and they have gained ground in the last few years. The hot or dipping process is used exclusively for the coating of sheets, and consequently it will perhaps be well to deal with this branch of the galvanizing industry first. An idea of the immensity of this branch of the industry may be gathered when we consider that the production of this commodity, which in the year 1895 was two hundred and four thousand tons (204,000), by the year 1907 had grown to a production of four hundred and ninety-seven thousand tons (497,000). The chief consumers of this commodity are Australia, South Africa, Argentine and India.

The term galvanized iron is one which for many years has been given to articles of iron coated with zinc, for the purpose of preserving the iron from oxidization by the atmosphere. When iron is thoroughly cleaned and freed from scale, it will, upon being dipped into molten zinc, become perfectly coated. If the iron is perfectly coated the atmosphere has no direct action upon it, but a thin film of oxide is formed upon the zinc coating.

Quality Feature

The quality of the galvanized sheet depends chiefly upon three things. Primarily, on the quality of black sheet iron —that is the sheet iron as it comes from the rolling mills—and upon the care exercised during the process of galvanizing. If the quality of sheet iron is poor, even a heavy coating of zinc will not produce a good sheet. It is essential that the sheet iron be absolutely clean and free from scale and cinder, otherwise it will not hold the zinc coating for long, and after a short time of exposure to the atmosphere spots of rust will appear, which eating into the surface expose the iron to rapid oxidization and corrosion. Secondly, the quality of the iron as regards ductility and toughness must be studied, for, if it is not sufficiently so, it will, on being corrugated, crack, and although the fissures may perhaps be so small as to escape a cursory examination, they will, on being exposed to the action of the atmosphere quickly corrode and render the sheet practically worthless. Thirdly, the quality of the finished iron depends to a very large extent upon the purity of the spelter used—spelter is the name given in commerce to the zinc blocks before being made into zinc sheets.

Dipping Only

When the trade was first established, the process universally adopted was that of dipping, no machinery being used. The bath employed was about 9 ft. long by 3 ft. 6 ins. wide by 4 ft. deep. A bar of "T" iron upon which was riveted an iron plate, just deep enough to go into the molten metal when the bath was at its lowest working level, was placed across the middle of the bath. The object of this was to divide the flux and keep the exit side in the best condition. A dipper and his mate were employed at the entrance side, and they together plunged the sheet into the molten metal, and by means of rods passed it under the iron plate before mentioned, bringing it up on the other side of the same through the flux. The sheet was then seized by "takers out"—two being employed—who gradually drew it out by means of tongs, and when the surface was sufficiently set plunged it into a tank of clean water. Afterwards the sheet was passed to the sawdust boxes, where it was dried. If it was desired to have a bright sheet, it was plunged into water before the surface was set—that is, before crystallization had begun. It was tried, with a view to economy in flux—that is, sal ammoniac, or muriate of ammonia as it is generally known in the trade—to utilize black foundry sand. It is apparent to anyone conversant with the process of galvanizing what a terrible practice this was, seeing that sand is not a fluxing agent for zinc. Its only economy, and that an imaginary one, was that due to the sand dragging on the surface of the sheet it would act as a flux. It created a large quantity of sand skimmings and oxide, besides the difficulty of separating the spelter and the sand when in a fine state. Several patent processes were introduced, among them being Heathfield's, Baylis's, and Carasco's.

Heathfield's Process

In this process a machine having several pairs of rolls was employed, the last pair being just above the surface of the metal, the object being to squeeze the surplus zinc off the sheets and give a uniform coating.

Baylis's Process

In this process the sheets after being pickled were passed through a pair of cold rollers upon which flowed a continual stream of water. From these rollers the sheet passed on to a bath which it entered by means of a pair of rollers fixed on the bath frame. It then passed by means of guides through the metal and emerged through the flux, which in this process was sand. They were then seized by a pair of studded rollers, passing onwards by means of an endless chain to a set of revolving brushes which brushed off the adhering particles of sand.

Carasco's Process

In this process the sheets passed through a pair of rollers on the bath and were conducted by means of guides into the flux box. From the flux box they passed by means of other guides through the metal and emerged through a pair of V-shaped wheels which gripped the sheets on the edges.

We now come to the process as carried out to-day and will deal with the machinery more fully.

Buildings

A building with a framework of light sectional iron and covered in either with asbestos, slates or corrugated iron sheeting serves the purpose equally as well as costly wood or brick buildings. Care must be taken to have a periodical inspection of the ironwork, and it should also frequently be coated with some good anti-corrosive paint, of which there are several upon the market. In arranging the buildings, the fact should not be overlooked that it is better to have the sheds used for corrugating, sorting and packing separate and detached from the galvanizing and pickling sheds. Attention also should be given to the ventilation of the buildings, especially in the case of the corrugating, sorting and packing sheds, and they should also be heated to obtain a dry atmosphere. This can be done by means of hot air heated by a steam heater, or a waste-coke heater, of which there are plenty in works of this kind.

Pickling

This is the first stage of the process after receiving the sheets from the annealing furnaces. There are two classes of acid used in this work, either sulphuric or commercial hydrochloric. If the former, the specific gravity used is 1.8 or 1.9 and mixed in the proportion of five parts of water to one of acid. In using this acid it is necessary to quicken its action upon the sheets by warming it to a temperature of about 90° to 95° F. by means of a steam jet, which conveys the steam to about 2 ins. from the bottom of the vat by means of a lead pipe of about ½-in. bore.

If hydrochloric acid is used as the pickling agent a "Twaddell" of about 35 is employed and the proportions are one of water to one of acid. By using this acid, it is, as a rule, unnecessary to warm it up by means of steam except in cold weather.

Of course, the adoption of acid used for pickling depends to a certain extent upon local conditions, but, speaking generally, it is preferable to use hydrochloric acid, since the sheets do not require soaking after pickling; although a water vat is often provided so that when the sheets are taken out of the pickling vat, to await being dipped by the dipper, they may be put in the water vat to await dipping, thus ensuring that they are kept perfectly clean. The fumes generated by the hydrochloric acid pickle are not so annoying as those generated by the sulphuric pickle. The working cost of both pickles is approximately the same due to the different quantities of acid used. The time occupied in pickling a batch of sheets is approximately the same under both systems and varies from 15 to 20 minutes, according to the condition of the iron and also of the pickle.

Pickling Vats

These vats are best constructed of good York stone, the vertical joints being joined together by means of solid round indiarubber pulled tightly together by means of clamps and rods. In the opinion of the author, clamps are better dispensed with. It is only necessary to drill the flags and pass the tie-rods through them direct. The horizontal joints are best made with flannel well smeared and kneaded with a paste of white lead and boiled oil. This prepared flannel is then evenly laid upon the portion of the stone which has already been truly dressed for the purpose. The side flags are then laid upon this flannel, their weight being found sufficient to close the joints securely. If care is taken in the building up of these tanks, they will last for many years with very little attention. Owing to the continual charging and discharging of the vats with sheets some protection is necessary for the tops of the vats. A cheap and efficient method of overcoming this difficulty is to protect them by means of channel iron, the wear being taken by this iron. This will be found to well repay the extra outlay, as the renewal of a stone side is a somewhat costly job. The bottom of the vat is protected by blue bricks set in china clay and pitch, about two courses deep. A hole about 3 ins. diameter for emptying the vat is provided at one end of the vat, being plugged up by means of a wooden taper plug covered with flannel. A cheaper vat can be made of pitch pine lined with lead and its bottom protected by means of elm or pitch pine planks wedged in to prevent the sharp edges of the sheets cutting the lining.

Although the initial cost of the stone vats is far in excess of the wooden ones, their life is considerably longer and the maintenance is not so high. All tie rods and clamps should be regularly and frequently coated with a mixture of equal parts of lime and tar, when it will be found that they will last a considerable time, although often being splashed with acid.

The second or intermediate vat is generally constructed of pitch pine planks whose top sides are likewise protected with channel iron to prevent wear due to the rubbing action of the sheets. The sheets after being fed into this vat from the pickling vat by manual labor are, in some cases, fed into rollers fixed on the side of this vat, and thus conveyed into the dipping machine; but it is, in the author's opinion, better that the sheets be taken by hand from this vat and fed into the dipping machine by the dipper, thus ensuring a square start and a safer passage of the sheet through the galvanizing bath.

Bath and Bath Frame

The bath is made of the best quality mild steel plates 1 in. to 1¼ ins. thick, being either riveted or welded, a convenient size being 5 ft. 9 ins. by 5 ft. 9 ins. by 3 ft. 6 ins. deep. This is set upon a foundation of brickwork covering the whole of the bottom, rising about 9 ins. round the sides, so as to prevent, as far as possible, the bath being burnt when the dross accumulates at the bottom.

These baths are fired by various means, generally open coke fires, or the bath may be surrounded by means of cast iron covering plates over the fires, with suitable firing holes cast in them, having suitable lids, so that the intensity of the fire may be regulated. These plates are best cast in angle form and bolted together in such a manner that they may form a fixing or stay for the brickwork, at the same time being easily removable in the event of the bath becoming leaky, necessitating immediate and quick repair. Great care is needed in the firing of the bath, as upon this depends to a very large extent the life of the same. For successful working it is necessary to maintain an even heat in the bath so as to prevent undue formation of oxide caused by overheating of the metal on the one hand, and excessive deposit of metal on the sheets caused by too low a heat on the other hand. The temperature to aim for is from 830° to 850° F., which will give a satisfactory result. Care should be taken to instruct the dipper, and likewise to see that the instruction is carried out, that he must clean daily the sides of the bath on the fire side and internally, as far as possible of oxide creepings by means of a scraper bar. This considerably helps in prolonging the life of the bath, preventing overheating of the same—as oxide is an exceptionally bad conductor of heat and when formed and allowed to remain causes burning of the plates and ultimate failure of the bath.

Starting a New Bath

When the galvanizing bath has been properly set, considerable care must be exercised in filling it with spelter to prevent the bath from being runed when the fires are started. In filling the bath with slabs of spelter, place them on edge in such a way that their flat surface will lie as closely as possible to the sides of the bath. By exercising a little ingenuity the slabs can be so placed as to practically cover the sides of the bath. This method of placing the slabs will lessen the danger of burning the bath on the first firing as there is cold zinc against all the heated surface. The slabs should also be arranged so that as the outside ones melt, those next to them will be forced outward against the side of the bath.

Firing a New Bath

In heating up the bath for the first time, one should take care that the work is not hurried. Under no circumstance attempt to melt out a bath for the first time in less than 36 hours. Until seplter begins to melt the fuel should not be allowed to attain a depth of more than 12 or 15 ins. in the fire spaces, and the air holes should be regulated so that the fires will not burn so strongly. As the metal melts the depth of fuel may be increased, but it should never be more than 3 or 4 ins. above the surface of the metal in the bath. Of course, it is rather difficult to determine just the depth of the molten metal, but it is easy to be on the safe side even if a longer time is taken in melting out.

Leaky Baths

It often happens that a bath is worn more in one particular place than another. This is often caused by extrem. draughts forcing the fire in that particular spot, but by careful stopping it is possibly to considerably lengthen the life of a bath. All repairs should be carried out in a careful manner, and as quickly as possible consistent with first-class repairs.

The location of a leak soon makes itself apparent by excessive fumes due to oxidization of the metal. The first operation is to remove the fire and ashes from the vicinity of the leakage when the size of the same can be observed. No attempt should be made to stop the leak by thrusting the point of a poker in the hole, as this may cause the hole to become larger, especially if the plate has become very thin in this particular place. If the hole is very small it can be stopped, but if the molten spelter flows in a continuous stream it is necessary to lower the level of the metal below the level of the hole. If the hole is large the metal can be caught in moulds while the operation of lowering is going on.

The next step is to build up from the bottom of the fire space a column of firebrick to within a foot of the hole. A piece of R.S. channel about 5 ins. by 3 ins. is then put in an upright position and tightly wedged to the bath from the brickwork and the brick column is built up to the level of the surrounding brickwork. In the intervening space, formed by the channel, some fireclay, made into a stiff paste, is put and well rammed, so as to form a good foundation, which should reach to within 5 ins. of the hole. A mixture of iron filings and sal-ammoniac is then put in on the top of the fireclay and also well rammed until it is a few inches above the aperture. The remainder of the space so formed is then filled in with fireclay and well rammed. This should be allowed to remain a couple of hours to set, when the bath may again be put in service.

GOOD BUSINESS ORGANIZATION

By Geo. H. Gibson

GOOD business has been defined as the art of selecting probabilities, and it is certainly true that the greatest successes in the engineering businesses have come to men who had the ability to do the following things: Foresee the need or opportunity, develop the solution, and focus the attention of the public upon the problem and its solution. As examples, I might mention Edison with the incandescent lamp, Westinghouse with the air brake and alternating current transmission, Hunt with rope transmission, Sturtevant with fans and blowers, De Laval and Parsons with the steam turbine, Babcock and Neier with the water-tube boiler, Diesel with the oil engine, the Wheelers with surface condensers, Hill with technical journalism. Thurston with technical schools, Patterson with the cash register, Herschel with water meters, Kent with his handbook, and many others.

The inertia and prejudice which must be overcome in the introduction of a new device may be illustrated by the experience of Corliss with his variable cut-off four-valve steam engine. After he had perfected and demonstrated the remarkable savings of his engine as compared with the engines then common in this country, he was still compelled to give the engines away and to take his payment in the fuel saved during the first year's operation, in order to make headway.

Many people have the idea that the invention is the important thing. Very few engineering businesses, however, are founded altogether on exclusive and basic patents. They are based rather on a combination of scientific knowledge and business sagacity, with the help of such protection, monopoly or trading advantage as can be obtained from the detail patents which it may be possible to secure as the development of the art unfolds itself. A man may have the germ of a good idea for a successful business, but still nothing that can be protected by a patent, even though patentable improvements will doubtless be discovered upon developing the idea. Nevertheless, the essential factor is the broad judgment or foresight which leads him to take up certain matters at a particular juncture, and not the specific mechanical contrivances by which he may carry out his ideas. In such cases, the best protection to the idea is advertising by means of which he can promptly get the full benefit of the potential demand for his product before competitors have had time to imitate and develop. Once he has his organization and business well under way, competition will be at a disadvantage.

For businesses up to a certain size, there is nothing that will beat one-man efficiency. The man who can see a need or an opportunity for a need, and act accordingly, is fit to be the head of a business, if he is also an administrator. However, the organization of modern industrial enterprises branches out into a great multiplicity of specialized details, and we cannot always get in one man all those qualities of genius that are necessary in the inventor, in the captain of industry, and in the promotion expert. We therefore have performing these functions a number of men who may be described as follows:

First, there is the general strategist, who may have the title of president general manager, chief engineer, and not infrequently sales manager, since the study of how to sell a product as already built leads almost invariably to the discovery of improvements whereby it can more easily be sold in larger volume and at a greater profit. It is his disposition and function never to be satisfied with things as they are. He is continually studying the trend of engineering scientific and business developments with a view to visualizing their probable future course. His policy is to build a monopoly of information and brains, and then to serve the public with little or no competition by having the best solution for each new problem as it arises.

PYROMETER DEVELOPMENTS

(Continued from page 312.)

instrument, so that when a balance is reached, no current flows. A galvanometer is used to indicate the point at which no current is flowing, and the pointer on the galvanometer then indicates zero, the voltage of the thermo-couple being opposed to the dry cell. The advantage of the potentiometer method of measuring temperature lies in its extreme precision, and its independence of resistance changes throughout the thermo-couple circuit. It has the disadvatage compared with the millivoltmeter method in that it is not direct reading, and that some outside source of current, a dry cell for example, is necessary as a source of current to oppose the thermo-couple.

Radiation Pyrometers

The radiation pyrometer is a development of the thermo-electric pyrometer. Instead of placing the thermo-couple inside the furnace, where the temperature would be so high as to destroy it, it is placed in the back of a tube in front of a mirror. The rays of heat from the furnace enter the tube and strike the mirror and are brought to a focus on the thermo-couple junction. This instrument has a particular field where temperatures must be measured from 2,800 degrees Fahr. up, and it is possible to secure an accuracy within 1 or 2 per cent. with this type instrument, if the instructions as to its use are properly carried out. It is not recommended for service where a thermo-electric pyrometer with base metal or platinum thermo-couple can be used.

It is very essential if accurate results are to be secured from pyrometers that they be re-standardized at frequent intervals. The freezing point of pure salt is an excellent method of testing thermo-couples, or of the complete pyrometer consisting of the thermo-couple, leads and instrument. Insert a thermo-couple in a small crucible containing pure salt; ordinary table salt is satisfactory and heat the salt to about 1600 degs. Fah. Remove the crucible from the heat and allow it to cool off. At the freezing point of the salt which will be indicated by the temperature remaining reasonably constant for four or five minutes, the pyrometer should read 800 degs. Cent., or 1,472 degs. Fah. The melting point of a number of different metals is quite satisfactory for checking purposes.

The metals most generally used for this purpose, and their melting points follow: Tin, 450; zinc, 787; silver, 1,761, and gold, 1,945; copper, 1,929; aluminum, 1,157, and platinum, 3,227 degs. Fah. The Bureau of Standards at Washington tests pyrometers and thermo-couples for manufacturers in the United States, and it is a good plan to have a standard platinum or base metal thermo-couple tested at the Bureau since its laboratories can furnish the millivolt values for the thermo-couple. This data can be retained as a primary standard to test the secondary thermo-couple. The cost of such a test is usually about $10.

Automatic Temperature Control

The greatest future in pyrometry undoubtedly is along the line of automatic temperature control. Instruments which automatically control the temperature of electric furnaces have already been designed. By means of solenoid operated switches the circuit is opened and closed through the rheostat, maintaining the temperature constant within 10 degs. Fah.

It may be suggested that the various steel manufacturers who are interested in the improvement of heat treating methods can be of great assistance to pyrometer manufacturers in co-operating with them to test out new devices in an endeavor to improve on present methods.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

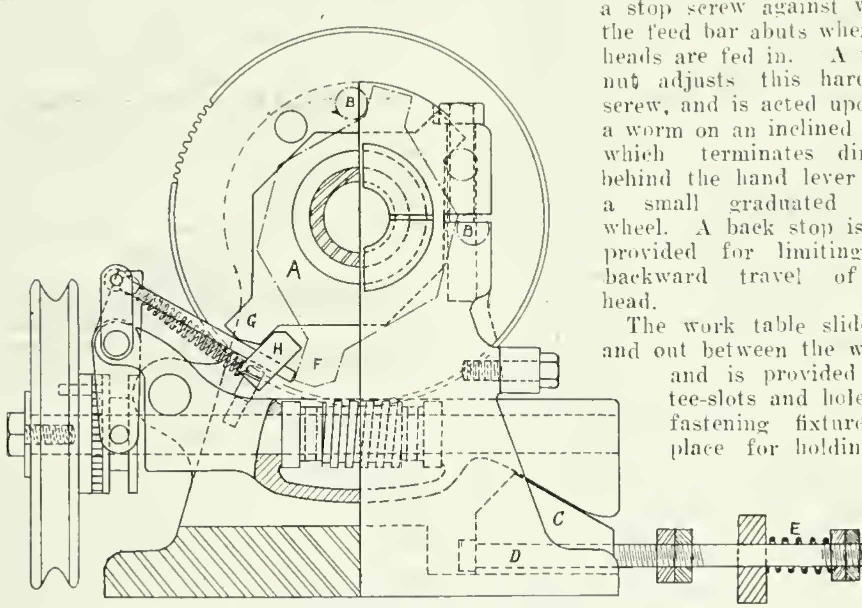
WHAT is claimed as the largest machine of its type now on the market is shown in the cut here, shown in the accompanying engraving, which illustrates a recent product of the Gardner Machine Co., Beloit, Wis. The No. 15 double spindle grinding machine carries 20 in. ring wheels or 24 in. disc wheels both of which types of grinding members are interchangeable.

Each spindle is mounted in a sliding head which in turn moves in an adjustable sub-base which can be securely fastened in any desired position according to the requirements of the work. The cast iron hoods which guard the wheels are fastened to the inner ends of the sub-bases and move only when these are adjusted for position. The sliding heads work through a felt lined hole in the hoods and have a combined lateral travel of 3½ in. when both heads are moved toward the centre simultaneously; either head, however, may be locked in position and one head only moved. As shown in the engraving the sub-bases are set well apart for grinding opposite sides of very wide pieces, but when grinding thinner articles the sub-bases are moved closer accordingly and secured to the bed by bolts. This adjustment is conveniently made by pinions carried in brackets attached to the sub-base and engaging with a feed rack which extends across the front of the bed, a detachable wrench being used for this purpose.

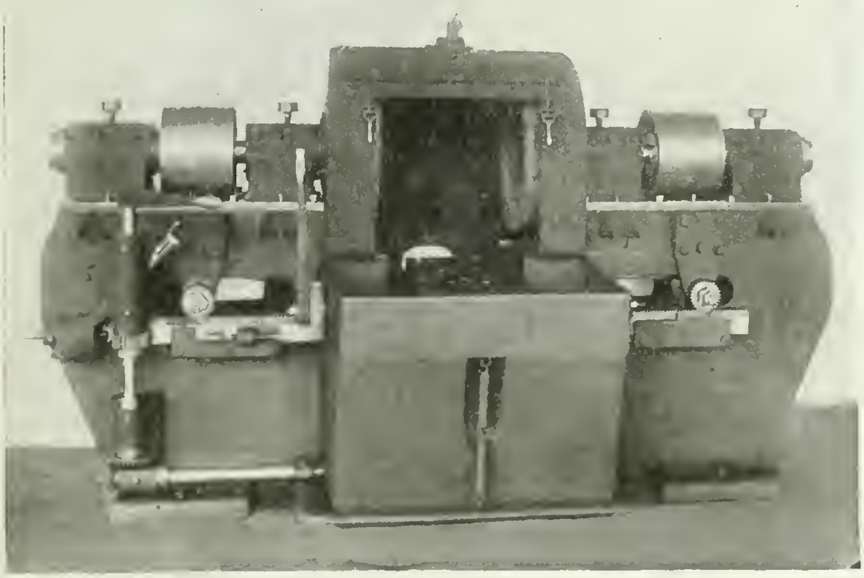
The feeding of the heads is done by a vertical shaft at the left of the machine. A pinion on this shaft engages with a short length of rack on front of the 3 in. square steel feed bar, and a horizontal hand lever is mounted on the upper end of the vertical shaft. When this hand lever is pulled to the right the feed bar moves to the left and revolves the pinions meshing with the rack on its upper surface. The shafts on which the pinions are mounted transmit the motion through suitable bevel pinion gearing to spur pinions which mesh with racks fastened to opposite sides of the sliding heads so that the heads move in opposite directions or to and from each other. A treadle extends around the front of the machine and operates the hand feed shaft by bevel gearing so that the operator may control the machine from either side of the work.

At the extreme left of the feed bar is a stop screw against which the feed bar abuts when the heads are fed in. A worm nut adjusts this hardened screw, and is acted upon by a worm on an inclined shaft which terminates directly behind the hand lever with a small graduated hand wheel. A back stop is also provided for limiting the backward travel of the head.

The work table slides in and out between the wheels and is provided with tee-slots and holes for fastening fixtures in place for holding the work. It is moved back and forth by rack and pinion operated by hand lever at the left side of table. This lever is attached to a large gear which meshes with a pinion on the outer end of the rack pinion shaft. When a slower and more powerful movement of the table is required, the gear and pinion are reversed. The shaft carrying the hand lever is extended across to other side of bed from which it can be operated if desired. The entire base of machine is cored out with solid bottom and connected with the water basin in front of table giving a capacity of 70 gals. of lubricating compound. Grinding may be done either wet or dry: when dry, a covered opening in the rear of machine directly behind the sliding work table is provided for attaching dust exhaust system. Nett weight of machine is 5,000 lbs. and the maximum opening between disc wheels is 24 in., and between ring wheels 20 in.



HALF SECTIONAL ELEVATION OF WORK-HOLDING DEVICE FOR THREAD MILLING ATTACHMENT.



HEAVY DUTY DOUBLE GRINDER.

SEMI-AUTOMATIC THREAD MILLING APPARATUS

THE accompanying illustrations show a thread milling device which has been developed in connection with munitions manufacture, and is now being placed on the market in a form adapted for inside or outside milling, and for any pitch up to ½ in., either right or left hand. It is used with a multiple tooth, straight relieved cutter, and finishes work at one revolution. Where a final finishing cut is required, the spindle by changing one screw will automatically make two revolutions, one for roughing and one for finishing.

The attachment will fit any hand or screw feed milling machine, and where a greater angle is being cut than can be taken care of with the clearance of the cutter, the apparatus can be raised or lowered so that the cutter will be directly underneath or on top of the work, allowing the cutter to be set at the proper angle to clear the threads. The principal features are a work carrying spindle carried in a suitable casting and provided with means for revolving it and feeding it axially according to the required pitch. The spindle has a collet capacity of 1¾ in. on pieces not more than 4 in. long, and has a 1 in. hole clear through. The portion containing the collet is mounted in the main bearing of the frame, while the portion extending backward has mounted on it a worm wheel and stop mechanism, and also a lead screw, which engages with a nut carried in the rear spindle support.

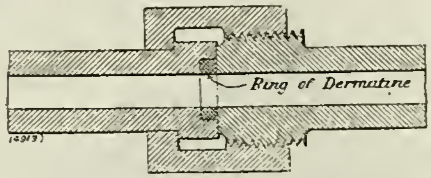
The worm for revolving the spindle is carried in a swinging bracket, the arrangement of which is clearly shown in the line drawing. It is driven by a rope pulley with dog clutch which automatically engages when the worm is meshed with its gear. This latter operation occurs when the table is fed by hand when the rod D is held by a bracket attached to a stationary part of the machine, causing the wedge block C to raise the free end of the worm shaft and engage the worm with worm wheel. A stop plate A revolves loosely on the hub of this gear and is stopped by the two pins B.B, two positions for which are shown, the amount of revolution obtained being about one and one-tenth.

The action of tightening up the collet brings plate A to the position shown by the full lines, point G being against stop H. The revolving of the work brings the plate into position shown by point F which contacts with a push rod to disengage drive clutch on worm shaft. On running the table back again, stop nuts on rod D release wedge block C and allow worm to drop. The spring E is provided to bring the worm into mesh and start the work revolving before the cutter is in contact, the compression of the spring allowing further forward motion to full depth of cut.

After a piece is removed, the stop plate returns to point G through the action of screwing up the collet. The machine is automatic in the actual milling of the thread and produces work to the usual high degree of accuracy obtained with thread milling machines. The American Ammunition Co., Borderton, N.J., are the makers of this attachment.

HYDRAULIC JOINT PACKING

IN a recent issue of the *Philosophical Magazine* the Earl of Berkeley and Dr. Burton describe a simple form of joint packing, which is, they state, tight to start with and maintains this tightness



HYDRAULIC JOINT PACKING.

up to the highest pressures they have employed, and which have attained 1,500 atmospheres, or say, 10 tons per square inch. As will be noted from the accompanying sketch, the pipe ends are faced, and a recess is cut in one to take the ring of dermatine shown. Before assembly, this stands just a little over, and is thus slightly compressed when the joint is tightened up. Either red or black dermatine may be used, but the red, being harder, is more easily machined. The joint is said to be equally good for water or oil, and is as suitable for a flanged joint as for a screwed coupling. It is also said to be as satisfactory with large pipes as with small.

NEW FORM SHELL

THE sketch Figs. 1 and 2 represents a new form shell invented by Stanley Frederick Stokes, Chatham, England, (103,270), in which one or more rifling bands formed of leather or other soft material are provided, the idea being that same will not injure the barrel of the gun, thereby greatly lengthening its life, and at the same time providing an efficient gas check. The band is shown

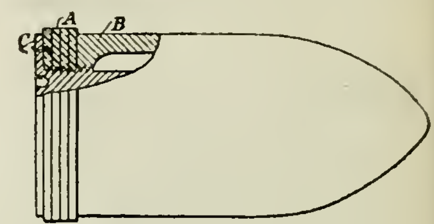


FIG. 1.

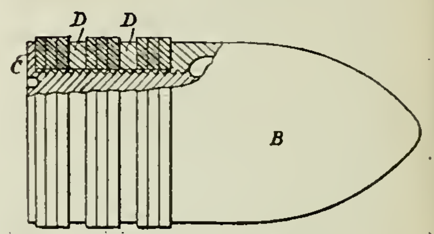

FIG. 2.

in Fig. 1 by a single ring A of leather between the body of the shell B and a clamping ring or plate C, which may either be threaded as shown, and screwed into place, or be formed as a plain ring or disc adapted to be adjustably held by screws or bolts, so as to permit the pressure of the gases when exerted on the back of the ring or plate to further expand or compress the ring A into close contact with the bore of the gun as the shell is ejected. The ring A may be formed of a single layer of leather if desired, or, as shown, of several layers arranged together side by side before the single plate C. If desired, a metal plate of smaller diameter could be arranged at intervals, such as between each layer of leather, so as to divide the ring A into several narrow bands. Or, again, several wide bands may be provided, as shown in Fig. 2, each of which is composed of several thicknesses of leather or like soft material, and separated by means of plates of metal D.

INDIVIDUALITY OR CO-OPERATION?

THE probable effect which a declaration of war by the United States will have on Canadian industries is the subject of much speculation and at the same time of no small concern to many of our manufacturers apart from those engaged in munitions making. In a crisis like that through which our Southern neighbor is now passing, exaggerated reports and vague possibilities are too readily accepted by a public accustomed to sensational statements whose chief feature is magnitude.

Every loyal Canadian from munition worker to railroad magnate must experience some disquietude when reports are circulated indicating the probable action of the States in such matters as prohibiting the export of raw war materials. In view of the peculiar attitude adopted by our neighbors as they approach actual participation in hostilities, it is reasonable to ask whether they cannot help themselves more by extending the existing channels of help, rather than by endeavoring to enter the war as a self-contained semi-detached nation which wants to go on record as having fully equipped itself with every species of modern war machinery, made in America.

In view of the silent but none the less powerful influence of Great Britain in unexpected quarters, it is difficult to give credence to such reports as those which state that numerous ships being built in the States for British interests would be commandeered in case of war. The only nations on earth that the States can trade with are or ought to be those of the Allies, and such trading is done under the protection of the British navy. What benefit would accrue either to the States or the Allies from the taking over of ships now in course of construction?

The question of holding back material is almost parallel to the above in its unjustifiableness. While there is doubtless room for many more shells before an adequate reserve is available for defence against Mexico, the possible damage to the Allied cause from such a source is not to be compared with the handicap that would ensue through a serious restriction of Canadian output. What, we might ask, would have been the situation in Europe to-day if Britain had decided that all her coal and iron were needed at home?

It is just possible that the obsession for organization which is such a prominent feature of U.S. business to-day may act to obscure the real issues of the war, and result in shortsighted action, which, while directed toward the magnification of our neighbors' preparedness, will on the other hand be comparatively useless, if not actually harmful, although unintentionally so, to the Allied cause.

The absence of any official action tending to bring these and similar contingencies to a point for decision renders it impossible to forecast developments with any degree of definiteness. It is significant, however, that a clause has been inserted in certain war office contracts in Canada forbidding the employment of labor outside the Dominion. Raw material and machinery are the principal needs of Canada at this time so far as the States are concerned, and any hurtful restrictions on these commodities will have to be justified by very extreme conditions not at present in evidence, if the participation of the States is for the benefit of the Allies as a whole rather than the United States individually.

STANDARDIZING MARINE ENGINE DESIGN

IN VIEW of the development taking place in shipbuilding and marine engineering within our borders, it may be of interest to note that quite definite steps have been taken in Great Britain in the direction of standardizing not only vessel construction, but that of the propelling, and in some instances, the auxiliary machinery as well. In another section of this issue will be found an article entitled "Guidance Specification for Triple Expansion Marine Engines for Cargo Boats," the compilation of which is to the credit of the Council of the North East Coast Institution of Engineers and Shipbuilders. With the prospect of several years activity ahead for marine enterprise in Canada, and the certainty that many of our metal working plants will find opportunity of participating in one or other of its departments, the fullest intimacy with the plans and projects in preparation and already launched is, to say the least, highly desirable.

The standing of the North East Coast Institution of Engineers and Shipbuilders is first rank, therefore its proposition for a greater uniformity of marine engine design and construction carries a powerful appeal. It is perhaps needless to say, that more or less difference of opinion is likely to be given expression to as regards some of the proposals put forward in the article, nevertheless, having in view the extreme dearth of shipping, and the imperative need that it be promptly remedied, there is little doubt that a common ground with but slight modification of the original proposals, will become acceptable to the various interests concerned. Canadian marine engine builders—actual and prospective, also those more directly concerned with the operating service, will find, in the data presented, a safe and reliable groundwork from which to create and develop a propelling machine at once substantial and utilitarian.

The Annual Report of the South African National Union says "Our motto should be to export nothing in the raw state which can profitably be converted into another article of higher value before it leaves our shores. This applies with equal force to agricultural products and the mineral wealth of the soil." A similar motto should be adopted by Canada.

The General Market Condition and Tendency

THE industrial situation is still somewhat unsettled, due to war influence, more particularly on account of the uncertainty as to what the United States is preparing to do in regard to the protection of her rights. That the Government will take active measures is now practically assured; this has already been reflected in the steel market, as indicated by the recent sharp advance in prices. The demand for steel has been stimulated by the prospect of increased consumption and a further advance in steel prices is certain. This week, tubes, black and galvanized sheets, have advanced, while higher prices on plates, rivets and wrought pipe are looked for in the near future. Operating conditions at the mills have improved considerably, due to more favorable weather and increase in supply of raw material; production consequently will show a material improvement over each of the preceding two months. The pig-iron market continues strong and prices are still advancing. The demand, particularly for basic iron, is more insistent than at any time previously, and indications point to considerably higher prices than at present obtain. In regard to non-ferrous metals, consumers appear to be awaiting developments. The demand recently has been light, but a buying movement will likely start when the United States Government becomes more aggressive in its war policy. The only price change to note is in lead, which is slightly weaker, due to lack of interest in the market. Prices of scrap metals are generally unchanged, but firm. Steel scraps are in good demand, as is also machinery cast iron. Castor and lubricating oils have advanced, while higher prices on gasoline are likely. The machine tool market is quiet, but indications point to an improvement in demand for tools for ordinary purposes.

Montreal, Que., March 26. The activity in industrial circles has again become settled after being disturbed over the possibility of a large railroad tie-up. The congestion that was so pronounced on all railroads is gradually being relieved and transportation of material is resuming more normal conditions. The situation is still featured by the continual rise in prices of all commodities, and the apex of this movement is apparently far distant. Hopes are entertained that the opening of navigation will relieve the situation, but indications point to insufficiency of production, rather than scarcity of transportation.

Pig Iron

The market is again featured by a general advance of approximately $2 per ton on all grades of American pig and this change will likely be reflected in future steel prices.

Steel

Conditions throughout the steel trade have shown little improvement during the week, although the congestion on the railroads is not so pronounced and delivery of material has shown considerable improvement. The buying pressure is, however, as great as ever and everything points to a further increase in this direction, as the preparations being made by the United States government will entail much larger production by the various steel mills. What the policy of the mills will be in this connection is not definitely known, but similar action to that taken by the copper interests is anticipated, and in any case it is more than likely that preference will be given to the requirements of the home government over that of foreign interests. This may create a shortage of much needed material for the Canadian market with a corresponding increase in prices. It has been reported that recent advances have been made with a view to lessening the export demand and providing better facilities for possible home demand. A feature of the continual rise in prices has been the noticeable decline in the placing of orders for structural building material, and it is thought that this will have a beneficial effect when the present war demand begins to fall off, as these interests will again enter the field when conditions become easier. The billet situation has again been subjected to advance, the Pittsburgh quotation on open hearth being now $75 per ton. Sheet bars are quoted at the same figure, an advance on the week of $10 per ton. A further advance has been made on forging billets the current quotation being $90 per ton. A scarcity has developed in ferro-alloys and prices have generally advanced, the price quoted on ferro-manganese being now $325 per ton, this being $25 higher than a week ago. Plate mills are unable to accept orders for delivery this year, and some mills are booked well into the first half of 1918. Increased facilities for production have been gradually placed in operation, but little relief has as yet been experienced in the pressure on the large mills. Local dealers report a good market in plates but state that it is very difficult to get satisfactory delivery. Prices on 3-16 inch tank plates are ½ cent higher, the quotation being now $6.60 per hundred. Sheet mills are very active and following the advances of raw materials and sheet bars, both mills and dealers are quoting higher prices; dealers here have been forced to act in this connection and quotations this week are about ¾ cent per pound stronger than last week, the price asked being $6.25 for No. 28 black sheets and $6.70 for No. 10 gauge. Makers of steel shafting report a lower discount on list prices. Wire and wire products continue very brisk, the recent advance apparently having little effect upon the steady demand. Nuts and bolts, which have remained stationary for some time, are expected to advance to a higher level within the next week or two. The demand for wrought pipe is very insistent, but makers are unable to comply with the wishes of customers owing to the crowded condition of the pipe mills. Heavy premiums are freely offered for the acceptance of orders of boiler tubes, but in many cases mills are so filled up that even this consideration is no inducement. Local dealers have revised their price lists on both lap-welded and seamless tubes, the advance being approximately 15 to 20 per cent.; the changes wil be found in the selected market quotations.

Metals

The metal market has experienced a little excitement over the recent action of the United States in regard to copper requirements. Whether this will spread to other metals is not yet known, but the early future will likely have some developments along these lines. Copper is firm. Tin is higher on reported sinking of tin laden vessels. Spelter is firm and slightly higher. Lead is slightly weaker abroad but stronger here. Antimony is higher in New York, but easier on the local market. Aluminum is steady and firm.

Copper.—The present market is somewhat influenced by the recent offer by large American producers, to supply the government, in event of war, with copper at a price greatly below that prevailing on the open market. This has caused some uneasiness among consumers, who are showing a certain reluctance to place orders for far future delivery, believing that this latest move on the part of producers may ultimately result in lower prices to outside customers. While the price quoted seems low when compared to that asked from other sources, the extraordinary circumstances must be taken into consideration when summing up the situation. The requirements for the U.S. government will likely be a very small percentage of the total production of the mines and smelters, and the general situation must be governed by the outside demand and supply, which at all times is the essential factor in price quotations. With copper steady in London, the New York market has developed a weaker tendency; lake having declined ½ cent and electro 1 cent per lb., the price quoted for each being on the basis of 35½c. per lb. Local conditions remain unchanged, with lake and electrolytic at 43c. and castings at 40c. per lb.

Tin.—The market in tin has increased in strength during the past week without any apparent reason, other than the report that a tin laden vessel has met with disaster, or that some sort of tax has been placed on tin shipments. These rumors have disturbed the even tone of the market and created a nervous situation. The position of tin meantime, is one of increasing strength, the market in London and New York having advanced. The movement in New York has resulted in a rise of 3 cents on the week, the price quoted being now 56¼c. per lb. The local situation has followed that of other centers, and dealers here are quoting 56½c. on an active market.

Spelter. — Following a brief active movement earlier in the week, this metal has again settled into a quiet position, with producers sitting tight and not pressing sales. Uncertainty regarding the early future has apparently dampened the ardor of purchasers and the activity is one of immediate necessities rather than covering for future requirements. New York is ⅛ cent stronger, but with an unsteady tone. Dealers here are quoting 15½c., an advance on the week of ½ cent per lb.

Lead.—Conditions in the lead market are unchanged. The demand is still good, but the supply is better and railroad conditions have shown marked improvement, with the result that considerably more metal is available. A decline of ⅛ cent is noted on the outside New York quotations and further weakness may develop. The market here, however, is quite strong and dealers have advanced their quotations to 12¼c. per lb., an advance of ¼ cent on the week.

Antimony.—Owing to the scarcity of spot metal the market is retaining its strength and prices on the New York market have been advanced 2c. per lb. Local dealers are quoting 30c. on a steady market, this quotation being 3c. lower than a week ago. The supply is good, but the demand has fallen off a little.

Machine Tools and Supplies

While the demand for machine tools is not as excessive as some months ago, the volume of business is still of a very satisfactory nature, and manufacturers are kept fairly busy in supplying the needs of those makers of munitions who are constantly increasing their output, or replacing tools that have depreciated in productive ability, through continual operation. Shipyard activity is gradually assuming increased proportions with the result that impetus has been given to the manufacture of a different type of machine tool than that required for the production of shells. Where quantity was the feature in shell machinery, the type of tool necessary for marine equipment will require more attention to certain features in design and capacity that have practically been eliminated during the past two years. While shell equipment has been confined largely to special tools, that required for shipyards, marine engines, etc., will be more of a general nature. Prices of machine tools and supplies are well maintained owing to the abnormal high cost of raw and semi-finished materials.

Scrap

The market is at present in a high state of excitement and developing a variable degree of uncertainty. The recent action on the part of the United States copper interests, in announcing their intention to supply the requirements of the government, in the event of war, at a figure greatly below that of the open market, has caused some uneasiness on the part of dealers, as the conflicting conditions would probably have a depressing effect upon the scrap copper market. While copper is the only metal so far considered in this connection, it is conceded that concessions may be offered in other lines of industry, which would result in a general disturbance of present conditions. With the exception of coppers, which are steady, the movement of prices is upward; machine compositions are ½ cent higher, the quotation being 23½c. per lb. A similar advance has been made on brass clippings and turnings, the price asked being 19 and 16 cents respectively. The heavy demand for heavy steel scrap has had the effect of making the market stronger, this week's quotations of 16c. showing an advance of 3c. per lb. Steel turnings have been subjected to a similar advance, the current price of local dealers being 12c. per lb. Old boiler plates and rails are also higher, the quotations of 15c. and 17c. representing respective advances of 3c. and 2¼c. per lb. Malleable scrap at 15c. is 1¾c. stronger than last week. Wrought iron pipe is quoted at 12½c., an advance of 2c. per lb. Old lead is higher, heavy being quoted at 9c. and tea lead at 7½c. Scrap zinc at 9c. is ½ cent higher than that previously quoted.

Lyons Fair.—The Fair at Lyons, France, which opened on March 19, will close on April 1. Canadian manufacturers are among the exhibitors.

Toronto, Ont., March 27. — The continued advance in prices of steel is perhaps the most important feature in industrial circles. The effect is far-reaching in that the cost of so many finished products is increased. Manufacturers using iron or steel as raw materials have for some time been obliged to raise their prices owing to the increase in production costs, while labor costs have also been going up. In addition, the shortage of steel has restricted manufacturing activity and curtailed output. The situation on the railways is somewhat improved, there being less congestion, but shipments of goods are not coming forward as freely as is desirable; this, of course, is also hampering manufacturing operations.

Steel

The anticipated increase in war demand for steel in the United States is affecting the situation in Canada. This has already been evidenced by the recent sharp advance in prices and the end of the upward movement is not in sight. The large increase in tonnage that will be required will make the congestion at the mills more acute and force prices up. War demand will take precedence over all other business and further increase the already heavy tonnage that has been sidetracked pending a return to more normal conditions and prices. Thus, what might be called reserve or latent tonnage will be an important factor in the steel trade when the time for readjustment comes after the war. It will tend to steady the market when the more urgent war demand falls off. The enormous demand for ship plates and shapes continues to be the chief feature in the market. It is understood that the Imperial Munitions Board contemplates an expenditure of approximately $25,000,000 on steel ships, the construction of which will be put in hand as rapidly as possible under the circumstances. The rapidity of construction will depend upon the supply of steel obtainable and available capacity of shipbuilding plants to undertake the work. The U.S. Steel Corporation has recently accepted an order for 5,000 tons of ship plates and 2,000 tons of angles for quick delivery to a Canadian shipyard. The quotations given for plates in our selected market quotations are warehouse prices and an advance is expected shortly. The mills have withdrawn prices on ship plates owing to their sold-up condition and difficulty of promising deliveries. Boiler tubes both seamless and lapweld have advanced about 10 per cent., very few makers of iron or steel tubes quoting for delivery this year. Higher prices on wrought pipe, boiler rivets, bolts and nuts are expected in the near future.

Prices of black and galvanized sheets are higher following the recent advance in the primary market. Black No. 28 are quoted at $6.75, and No. 10, $6.50. Premier galvanized No 28 are now $7.95, and 10¾ ozs., $8.25 per 100 pounds. As might be expected the market is very strong and a further advance may be looked for. The demand for black sheets is very heavy and deliveries are getting more backward all the time, while output is restricted on account of the scarcity of sheet bars.

The steel market in the United States is very strong with the volume of business steadily increasing. The annual report of the U.S. Steel Corporation recently published reveals the unprecedented conditions now prevailing in the trade in America. Export demand shows little indication of diminishing while domestic demand is more insistent and will be augmented considerably by Government requirements. Prices on all steel products are very firm and further advances are certain.

Pig Iron

The market continues very strong with urgent demand for all deliveries. Prices continue to advance in the U.S., affecting practically all grades of pig iron. At Buffalo, lower grade foundry irons are being quoted at $39, furnace, and higher silicon grade, $40 furnace. Domestic pig iron is still quoted at $43, but an advance may be looked for shortly.

Scrap

The scrap market continues firm and prices generally are being maintained at levels quoted last week. Heavy melting steel continues firm and is in good demand, while low phosphorous scrap is also active. No. 1 machinery cast iron is in good demand at unchanged prices. Prices of copper and other non-ferrous scrap are easier with fair demand. Business locally continues good, but the outlook as to the future for scrap prices is somewhat uncertain. Indications point to higher rather than lower prices on all steel and cast iron scrap, but on copper and brass, etc., scrap, the outlook is unsettled.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Machine Tools

There have been no developments of importance during the week in the machine tool market. The character of business appears to be gradually changing from munitions plants to what may be termed ordinary business. Some interesting orders have been placed recently with local machinery houses for equipment for the new Camp Borden aviation plant shops, and other business of similar nature is pending.

Supplies

The expected advance in lubricating oils is in effect, machine oil being now quoted at 26c. and black oil 13c. per gallon in barrel lots. Castor oil is also up, the new price being 27c. per pound, while standard cutting compound is a shade higher at 6.15c. per pound. The low range for babbitt metals is now 14c. as against 13c. formerly. The new discount on miscellaneous wire nails is 60 per cent. as compared with 65 per cent. formerly. Turpentine has declined 2c. and is 69c. per gallon, but linseed oil is unchanged.

Metals

The situation in the metal markets shows little change since last week except perhaps a weaker tendency in prices due to lack of demand. This, however, has not as yet had any effect on prices with the single exception of lead, which has declined slightly. The purchase of copper by the United States Government at a price rather better than 16½c. per pound has not as yet affected the market, and may not in the future, as the amount involved is not very important when compared with the annual production of this metal. Business locally continues brisk and the outlook for the trade is favorable.

Copper.—The most important feature in the market this week has been the purchase of 45,500,000 pounds by the U.S. Government at a shade better than 16½c. a pound. Although this is about 20c. lower than the market, prices have not as yet declined, but the tone is a little easier. The amount of copper involved, however, is not very important compared with the annual production, although further transactions on the same basis might probably materially affect the market. Local quotations are unchanged and nominal at 40c. for lake and electrolytic, and 39c. for castings copper.

Tin. — Considerable strength has developed in the market as a result of higher prices in London. The demand, however, has been light, and New York prices are still nominal. Local prices unchanged at 56c. per pound.

Spelter.—The market is dull with galvanizers, and brass mills are practically out of the market. Local quotations are unchanged at 14c. per pound.

Lead.—Prices are a shade lower, the market having an easier tendency, due principally to falling off in demand. The "Trust" price of 9c. New York is still held with independents ½c. to ¾c. higher. Local quotations are now 12¼c. per pound.

Antimony.—There continues to be a scarcity of antimony with very little metal offering. The market is quiet with quotations nominal and unchanged at 35c. per pound.

Aluminum.—The market is strong, but demand is light. Quotations are unchanged at 68c. per pound.

Sydney, N.S., March 23.—The production of the Dominion Coal Co. Cape Breton collieries for March will reach 340,000 tons, which is the largest monthly tonnage for a long time past. The increase is to some extent due to the fact that March has 27 working days, also to the fact that men are working more steadily, and that the drain from recruiting has been stayed. The decline in production is shown by the figures for the financial year of the Dominion Coal Co., which ends March 31, these being, for the Cape Breton and Springhill Mines combined, less than the figures of the previous fiscal year by exactly one million tons.

One of the Springhill slopes has for some time been closed by an underground fire. Satisfactory progress is being made in the recovery of the mine, but it is not expected that the raising of coal will be undertaken until delivery is obtained from England of a turbo-compressor to provide compressed air for the underground pumps formerly operated by steam. The conveyance of steam pipes for long distances underground is an objectionable and uneconomical practice. The delivery of the necessary machinery has been delayed by the pressure of war work in England.

Labor matters at the collieries are a little unsettled, and there is a recrudescence of the United Mine Worker agitation that brought about the strikes of 1909. An application has been made to the Minister of Labor for a Board of Conciliation to adjudicate upon a request made by the U. M. W. for a 25 per cent. advance in wages. As the question of wages has for some time been the subject of negotiations between the management of the Dominion Coal Co. and the Provincial Workmen's Association, it is not thought the Minister will grant a board until the negotiations have been concluded. The American Federation of Labor has attempted the organization of the workmen of the collieries and munition works near New Glasgow, and also at Sydney Mines, but it is very unlikely any of the companies will hold negotiations with this body or any other body having its headquarters in the United States. International labor unions are not viewed with favor in Nova Scotia, where, seeing that local labor unions have already had a long and successful history, it is considered foreign organizations are superfluous and mischievous.

At the steel plants there has been some indication of a lessening in the volume of shell orders, which seems to point to increased ability of the Old Country plants to take care of requirements. An interesting happening of the week is the decision of the Dominion Steel directors to declare a four per cent. dividend, payable quarterly. This is the first dividend paid by the Steel Corporation since the initial dividend paid at the time of the amalgamation of the Steel & Coal Companies in 1910. It is expected that excavation work will shortly be commenced on the site of new coke ovens and by-products plant for the Dominion Steel Co. This installation will probably necessitate a new coal washer. More definite particulars will be available shortly. The opening of navigation looks like being later than usual. A large accumulation of shipments awaits the resumption of sailings from Sydney, as rail carriage has been limited during the past three months by congested roads and every conceivable kind of embargo.

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Trade Commissioner, Lonja del Commercio, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—G. B. Johnson, P. O. Box 109, Yokohoma. Cable address, Canadian.

HOLLAND—Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrivskaya, Ploshch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 27-28 Pearl Building, East Paradise, Leeds. Cable address, Canadian. F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom. J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbeged No. 4, Christiania, Norway. Cable address, Sontums.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Guelph, Ont. — The Flexible Conduit Co. are building a factory for making nitrogen lamps. Mr. Wheeler is the manager.

Prince Rupert, B.C.—The City Council are considering the question of erecting a cold storage plant to assist in the development of the fishing industry.

Toronto, Ont.—The Polson Iron Works have been granted a permit to erect an addition to their plant. The building will be a 2-storey structure 12 x 30 ft.

Guelph, Ont.—The International Malleable Iron Co. will build an extension to the main foundry building 216 feet long by 100 feet wide. Contracts have been let.

New Glasgow, N.S.—Fire on March 14 did considerable damage to the plant and boiler house of the Munro Wire Works. The loss is partly covered by insurance.

Porcupine, Ont.—The Northern Canada Power Co. is increasing the capacity of its plant from 8,000 h.p. to 13,000 h.p. One unit of 2,500 h.p. is now in the course of construction and the second unit will be installed this summer.

Matheson, Ont.—Machinery for the 50-ton mill at the Croesus is expected to arrive shortly and will be rushed to the property at once before the spring break-up. Lumber has already arrived, and, it is understood, everything is being put in shape for the reception of the machinery on its arrival there.

Port Arthur, Ont.—Despite its failure to get the Black Sturgeon pulp limit, the Port Arthur Pulp & Paper Co., composed of Toronto capitalists, is going ahead with its plant here. Offices have been opened in the city, and it is announced construction will start the first week in April. The pulp supply will be procured from independent operators and farmers. A. G. McCormack has resigned as Secretary of the Board of Trade to join the Port Arthur Pulp & Paper Co.

Victoria, B.C.—C. Silverman announces that he has purchased the machinery from the B. C. Equipment Co., of Vancouver, for installation at a mill at Sidney Inlet for the flotation process of concentrating ores, in connection with the mines there, which he has been developing for some months past. Mr. Silverman took over the old Dewdney property on Sidney Inlet. It is expected that the mill will be ready for use by June 15, and when complete it will cost in the neighborhood of $50,000 and will be capable of handling 250 tons of ore daily.

MUNICIPAL

Gleichen, Alta.—The town may purchase the local electric light plant owned by F. C. Vigor for $6,000.

Radville, Sask.—The Town Council are considering the erection of a $12,000 electric light plant.

London, Ont.—The City Council contemplates the installation of steam auxiliary equipment in connection with incinerator, to cost $25,000.

Sault Ste. Marie, Ont.—The Town Council have retained R. O. Wynne-Roberts consulting engineer of Toronto, to report on a 5-million gallon per day water supply.

Sherbrooke, Que.—The City Council propose purchasing the Two-Mile Falls Power near Weedon for $375,000. The question will be submitted to the ratepayers for approval.

Wolseley, Sask. — A by-law will be voted on by the ratepayers on April 7 to authorize the purchase of a gas engine, dynamo and building for a municipal power plant at $9,000. A. B. Hill is sec.-treasurer.

Trenton, Ont.—The Town Council's application to grant aid to the British Chemical Co., by granting exemption from all taxes, except school taxes, to pay $10,000 towards the purchase of the site for works of the company, has been granted.

Rosthern, Sask.—The Town Council has decided to proceed at once with the matter of establishing an electric light system in the town, and the firm of Murphy & Underwood, of Saskatoon, have been engaged to make preliminary estimates of the cost, the size of a plant required, location, etc.

Windsor, Ont. — Little interest was taken in the voting on Monday but all the by-laws carried. That to sell land to Peter Osterhout, a Windsor builder, for a factory site, carried by a vote of 54 to 14. A by-law giving similar privileges to the Canadian Oil Co. succeeded by 58 to 10, while the Max Goldman and Samuel Harris by-law was favored by 51 to 17.

Charlottetown, P.E.I.—The Commissioners of Sewers and Water Supply asked the Council that they apply to the Legislature for power to issue additional debentures, amounting in all to $15,000, to cover the cost of completing the installation of machinery, driving wells, extending the pipe line to new districts and increasing the pumping units in connection with the sewage system. The request was granted.

Toronto, Ont.—Estimates of the Street Cleaning Department for expenditures during 1917 call for $1,027,125. Commissioner Wilson asks $37,500 for plant and shop, $18,000 for the Strachan crematory and $34,450 for the Don destructor. The sum of $12,000 has been placed in the estimates for purchase of motor trucks for pick-up work and $12,000 more for motor trucks for ash removal from the Don destructor.

Toronto, Ont.—Expenditures of $3,552,976 by the Civic Works Department during 1917 are provided for in the estimates of Commissioner Harris. Under capital expenditure, Commissioner Harris is asking for $149,370 for reconstruction of the bridge on South Glen Road, and $63,200 for reconstruction of bridge on Spadina Road. There is an item of $25,000 for an additional pump and motor and connection to mains at the Riverdale pumping station. For main extensions the following sums have been placed in the estimates: High pressure fire system extension, $600,000; extension of distribution system in district east of Don River and north of Gerrard Street, $375,000; two 36-inch water mains under tracks of C. P. R. and G. T. R., from main pumping station to Front Street, $95,000.

GENERAL

Brampton, Ont.—The Gummed Paper Co., proposes to erect a two-storey addition to its factory and to install new machinery.

Ridgetown, Ont.—Hunt Bros., have purchased a site for their new six-storey mill, and work will be commenced at once on the $150,000 plant.

Aylmer, Ont.—Fire on March 21 destroyed the flour and feed warehouse of A. W. Pierce. The loss is estimated at $25,000, covered by insurance.

Chatham, Ont.—The property of the Blonde Lumber Co., including the large three-storey brick mill and considerable equipment, has been purchased by Archie Park for $13,000.

Montreal, Que.—A fire which broke out on March 20, in the basement of the Ingersoll Packing Co., St. Paul Street, spread to the adjoining premises occupied by the Continental Bag Co., Vaillancourt & Co., Geo. McGarry, A. A. Ayer & Co., and Z. Limoges, produce dealers The loss is estimated at $200,000.

Peterboro, Ont.—The Quaker Oats Co., whose plant was destroyed by fire last December, have decided to rebuild in Peterboro, and on the original site, in consequence of which the ratepayers will vote on a by-law to build a high-level bridge across the Otonabee River, near the new plant, which will permit Trent Canal traffic to the mills. The Government will assist in building the bridge.

TRADE GOSSIP

Samuel Osborn (Canada), Ltd., of Montreal, has been granted a license to carry on business in Ontario with a sum of not less than $40,000.

The Cincinnati Iron & Steel Co., Cincinnati, Ohio, are distributing a useful advertising novelty in the form of a circular metallic thermometer featuring the "Cisco" line of machine tools.

Kitchener, Ont.—Owing to the increase in the price of coal and gas oil the Light Commission has announced that the price of gas will be advanced until further notice from $1 to $1.15 per thousand, and that a minimum rate of 50¢ per month has been fixed.

Rate on U.S. Ships Higher.—It is reported from Washington, D.C., that a flat rate of three per cent. for insurance on vessels leaving American ports for ports of belligerent nations has been fixed by the government war risk insurance bureau. The highest rate has been 2 per cent.

Canal Engines for France.—Thirteen locomotives which were used on the construction of the new Welland ship canal have been secured by the Dominion Government for shipment to France to be used in war purposes. They are not needed here now on account of the closing down of the work.

Dominion Government Order Locomotives.—Fifty new locomotives have been ordered by the Government for the Canadian Government Railways. They will be constructed by the Canadian Locomotive Works at Kingston. The contract, which is intended to increase the motive power of the Government railways, was signed on March 21.

Shipyard for Canada.—It is reported that efforts are being made to secure the location in Canada of one of the British shipbuilding companies. This would involve the establishment of a yard on the Atlantic coast. It is understood that this is one of the subjects to be taken up by Sir Robert Borden and it is being furthered by the Imperial Munitions Board.

The Turbine Equipment Co., Toronto, have been awarded a contract by the Union Carbide Co., of Niagara Falls, N.Y.; and Welland, Ont., for three De Laval single stage, double suction, pumps, of 3-million, 2-million and 1-million gals. daily capacity respectively, to be motor driven.

They have also received an order from the Canadian Copper Co., Copper Cliff, Ont., for two single stage, double suction De Laval pumps. Each having a capacity of 3-million gals., daily.

Represents Russian Industry.—Gaston, Williams & Wigmore, Inc., have been appointed the commercial representative in the United States for the council of the All Metal Working Industries of Russia, which represents a union of the metal industries in Russia. The purchases to be made across the line will consist of machinery and equipment for the factories of the various members of the council and other materials.

The Turbine Equipment Co., Toronto, have been awarded a contract by The Imperial Oil Co., Church St., Toronto, to supply for their new plant at Dartmouth, N.S., 13-De Laval single stage, double suction pumps, ranging in size from 1500 gals. to 350 gals. a minute. The Imperial Oil Co., have also placed another order for two additional single stage, double suction, high lift De Laval pumps, each to be direct connected to 150 h.p. motors.

The Turbine Equipment Co., Toronto, have received a contract amounting to $19,000 to supply and install, 8-De Laval single stage, double suction centrifugal pumps, for the new filtration plant for the town of St. Hyacinthe. One will be 5 million Imperial gals. daily unit, another 4½ million gals. daily, and there will be 6 having capacity of 2½ million Imperial gals. daily. All these pumps will be connected direct to Canadian Westinghouse motors. They will also supply 40 h.p. motor driven roots blower, complete switch-board etc.

Marine Engineers Meet. The National Association of Marine Engineers held their closing banquet, following a series of successful Winter meetings, at the Sons of England Hall, Toronto, on March 22. At the previous meetings business managers for the Great Lakes district had been appointed and the presence last evening of the president and two members of the Great Lakes Council, and two members of the Grand Council, made for a large turnout. Three new members were initiated. The almost general adoption of the new wage scale by shipowners was the source of much gratification, and speeches were all of a most optimistic nature.

Joint Technical Societies Meeting.—The annual meeting of the Joint Committee of Technical Societies will be held in the Chemistry and Mining Building, Toronto University, Toronto, the evening of March 30th, and will be addressed by John Murphy, Chief Electric Engineer of the Department of Railways and Canals; Mr. Matheson, late of Colorado, but now Chief Engineer of the British American Nickel Corporation, and others. All engineers, whether or not they are members of any society, will be privileged to attend this meeting. Correspondence should be sent direct to the secretary of the Joint Committee of Technical Organizations, Ontario branch, Excelsior Life Building, Toronto.

U.S. Government Purchase Copper.—Advices from Washington, D.C., state that the principal American copper producers have agreed to furnish the Government copper needed for the army and navy during the coming year at 16 and a fraction cents a pound, about one-half of the current market price. Forty-five million pounds is the amount to be delivered. This solves one of the important problems in connection with large orders for munitions soon to be placed, and is the first big concession in response to the appeals to the patriotism of the country's industries since the navy's agreements with the shipbuilders and steel makers for profit cutting. The action of the copper producers was announced by the Council of National Defence.

Government Will Take Over Ross Rifle Factory.—The expropriation by the Government of the Ross Rifle factory at Quebec, to be operated on the lines of the Dominion Arsenal, will take place this week, according to present plans. Proceedings will be taken under the Expropriation Act, which, through the War Measures Act, has been extended in its scope. This action follows that of the Government in cancelling the order for the last hundred thousand of Ross rifles, resulting in the closing down yesterday of the factory. The manufacture of the Lee-Enfield rifle by the Government at the Ross factory is to be arranged for as soon as the sealed patterns and specifications arrive, and the machinery is adapted to the new rifle.

WOODWORKING

Danville, Que.—The Danville Chair & Specialty Co., will not rebuild their factory which was destroyed by fire recently. A new company may be formed to deal with the situation.

Belleville, Ont.—The plant of the Pearce Co., in Marmora Village, was totally destroyed by fire on March 22. The company was engaged in the manufacture of lumber, shingles and lath, and had a very extensive and well-equipped plant. The total loss is estimated at $25,000, with no insurance. F. S. Pearce is president of the company.

RAILWAYS—BRIDGES

Brantford, Ont.—Negotiations are still proceeding between the Lake Erie & Northern Railway and the Grand Trunk for the use by the former of the latter's entrance into Port Dover. In the meantime the formal opening of the line has been postponed.

Fort Frances, Ont.—The Fort Frances and English River Railway Co. will make application during the present session of the Legislature to incorporate a company with power to construct and operate a railroad from Fort Frances to English River via Kenora.

Victoria, B.C.—The Esquimalt & Nanaimo Railway is practically ready to start work on the construction of a new swing bridge over the harbor, to replace the present old structure, which the company declares is far too small and too weak to handle the freight and passenger traffic into Victoria.

TENDERS

Toronto, Ont.—Tenders will be received for a building until April 9, addressed to the Toronto Harbor Commissioners, 50 Bay Street, Toronto, Ont.

All information may be obtained by applying to the Architects, Chapman and McGiffin, 95 King Street East, Toronto.

Terrebonne, Que.—The Town Council are calling tenders for a shoe factory. The plans and specifications of this building can be seen in the office of Dupont Roy & Beaudoin Engineers, 225 St. James Street, Montreal.

Montreal South Que. — Tenders will be called sometime in April, for a 30-h.p. motor-driven turbine pump and a 150-h.p. gasoline engine-driven turbine pump for fire purposes, etc. E. Drinkwater, St. Lambert, Que., is the engineer.

Grandview, Man.—Tenders will be received until March 28, for two steel bridges. Plans, specifications and tender forms can be obtained at the office of the Highway Commissioner, Winnipeg, or from W. Dickie the Secretary-Treasurer at Grandview.

London, Ont.—Tenders will be received by the Board of Control until April 5, for general supplies, including hardware, harness, lubricating oil, rubber supplies, etc., and iron castings. Specifications can be obtained at the office of the City Engineer, H. A. Braizier.

Cartwright, Man. — Tenders will be received by the Rural Municipality of Roblin up to April 5 for abutments and steel work for four bridges. Plans, specifications and tender forms may be seen at office of Highway Commissioner, Winnipeg, or at the office of Secretary-Treassurer, Cartwright, Man.

Toronto, Ont.—Tenders will be received up to April 2, addressed to the chairman of Toronto Harbor Commissioners, 50 Bay street, Toronto, for the construction of harbor head walls. All information may be obtained by applying to the above address. E. L. Cousins, chief engineer and manager.

St. Felix de Valois, Que.—Tenders will be received until March 31, at the office of the corporation of the parish of St. Felix de Valois, for the construction of an iron bridge in this parish. The plans and specifications can be seen every day at the Office of the corporation. J. H. Lavallee, sec.-treas.

Winnipeg, Man —Tenders, addressed to the Chairman, Board of Control, will be received up to April 16, for the supply of labor and materials required in the erection of a 150 foot brick or concrete chimney for the Elmwood Incinerator. Plans, specification and form of tender may be obtained at the office of the City Engineer, 223 James Avenue.

Winnipeg, Man.—Tenders addressed to the Commissioners of the Greater Winnipeg Water District will be received up to April 16, for the supply of miscellaneous bronze castings, brass piping, etc., which enter into the construction of a Venturi meter. Specifications and form of tender may be obtained at the offices of the district, 501 Tribune Building, Winnipeg.

Winnipeg, Man —Tenders addressed to R. D. Waugh, Chairman of the Commissioners, Greater Winnipeg Water District, up to April 16, for the supply of approximately 12,000 feet of 48-inch and 1,300 feet of 60-inch cast iron pipes, together with numerous specials and gate valves. Specifications may be obtained upon application to the offices of the District, 501 Tribune Bldg., Winnipeg.

Winnipeg, Man.—Tenders, addressed to the chairman, Greater Winnipeg Water District Commission, at 501 Tribune Building, Winnipeg, will be received up to April 16, 1917, for the supply of one second-hand passenger coach, also one second-hand caboose, both standard gauge. Tenderers to supply own specifications. Further particulars on application to undersigned. R. D. Waugh, Chairman of Commissioners.

Hamilton, Ont —Tenders addressed to Chairman of Board of Control will be received up to April 5 for the supply and delivery of one combined motor driven flusher and sprinkler to conform to the following general specifications: Tank capacity, 1,200 Imperial gallons; truck not less than 5-ton; separate motor for flusher apparatus. Further particulars on application to the Secretary of Works Department, City Hall, Hamilton.

PERSONAL

William Walker has been appointed Acting Division Engineer, Eastern lines, Grand Trunk Railway, vice F. L. C. Bond, enlisted for Overseas Service.

Hon. Col. Harry Cockshutt, president of the Cockshutt Plow Co., has been appointed president of both the Brantford Carriage Co. and the Adams Wagon Co. in succession to the late J. A. Sanderson.

John G. Sullivan, of Winnipeg, chief engineer C.P.R. Western lines was elected president, at the closing session of the eighth annual convention of the American Railway Engineering Association at Chicago.

Michael J. McAndrew, of St. Thomas, Ont., traveling engineer of the Michigan Central Canadian lines, died suddenly at Victoria, Ont., on March 19. Mr. McAndrew was born at Niagara Falls, Ont., in 1859. He was appointed traveling engineer in 1906.

Anson J. Hopkins, who has been with the Canadian Fairbanks-Morse Co., in Vancouver, was recently appointed general head of the accessory department of that company, and is now organizing the work of this department in the firm's eleven branches.

Francis S. McMath, president of the Canadian Bridge & Iron Works, Walkerville, Ont., has been appointed a member of the Detroit Municipal Street Railway Commission. The commission is urged by the Mayor to begin quick work on the subway plans to relieve street congestion across the river.

Harold C. Upton has been appointed manager of the machine tool department of the Toronto branch of the Canadian Fairbanks-Morse Co. Mr. Upton has been with the company over nine years, at the Toronto office, having passed through all the departments. For the past three years he has been city traveller on general lines for the various departments.

George Henry Frost, founder and for many years publisher of *Engineering News*, died March 15 at his home in Plainfield, N.J., aged 79 years. He was born in West Hawkesbury, Ont., and was graduated from McGill University, Montreal, as a civil engineer in 1860. His civil engineering experiences covered surveying work in Wisconsin for the Chicago & Northwestern Railroad. In April, 1874, he brought out the first number of the *American Architect and Surveyor*, a monthly sheet, which in 1876 he made a weekly and renamed *Engineering News*. This in 1911 he sold to the Hill Publishing Co., New York City.

CONTRACTS

Tecumseh, Ont. — Canadian Allis-Chalmers Ltd., Toronto, have been awarded a contract for the pumps and electrical equipment for the waterworks system by the Eau Claire Waterworks Co.

Fredericton, N.B.—The local School Board has awarded the contract for the erection of the Charlotte Street School extension to R. A. Corbett, of St. John, at $17,000, and for the heating and plumbing to R. Chestnut & Sons, of Fredericton, at $6,000.

Port Arthur, Ont.—The Fegles-Bellows Engineering Co. has been awarded the contract of the construction of a complete grain treating plant for the Western Grain Co. new elevator to be erected on the same site as that of the Western Terminal elevator on the Kaministiquia River. The plant, which will have a total capacity of 175,000 bushels is to be built according to plans designed by the contracting company.

Hamilton, Ont.—Contracts for annual supplies have been awarded as follows: Brass work, H. Mueller Mfg. Co., Sarnia; special brass castings, Talman Brass Works, Hamilton; cast-iron pipe, Gartshore-Thomson Pipe & Foundry Co., Hamilton, $58 per ton, special castings, 5½c lb.; castings, Canada Iron Foundries, Ltd., Toronto, 5c lb.; lead pipe, Talman Brass Works, Hamilton, 15½c lb.; lubricating oils, Imperial Oil Co., Toronto; valves, Kerr Engine Works, Walkerville, 4 in. gate valves $11.50 each f.o.b. Hamilton.

Toronto, Ont.—The request of Canadian Allis-Chalmers, Ltd., to be released from a contract to supply six-inch cast iron pipe at $26.75 per length for the York Township water supply system was acceded to by the Township Council at a special meeting held here on March 21. The tender of the Canadian Allis-Chalmers, Ltd., to supply two 12-inch valves at $65 each was accepted as was that of Drummond, McCall and Co., for 200 six-inch stop valves at $29.65 each and 83 12-inch stop valves at $72.80 each. Tenders for hydrants will be called for shortly. Frank Barber is Township Engineer.

MARINE

Port Hope, Ont.—Acting upon the suggestion of the Department of Marine, the Port Hope Harbor Board will have the white light on the Port Hope lighthouse changed to a red light, as the white light was liable to be confused with the town lights.

Pictou, N.S.—At a well attended ratepayers meeting held on March 22, a resolution was unanimously passed authorizing the Town Council to ask for legislation to bonus a proposed steel shipbuilding plant to the amount of $50,000.

Vancouver, B.C.—The Grand Trunk Pacific steamer Prince Rupert, Captain Duncan McKenzie, running between Prince Rupert and Vancouver, is ashore on Conn. Island, one mile east of Lawyer's Island light, and is reported badly damaged.

Ottawa, Ont—J. A. Cunningham, of Vancouver, president of the Manufacturers' Association of British Columbia, was in Ottawa recently in connection with the closing of a contract with the British Imperial authorities for three 8,000-ton steamships to be built on the Pacific coast.

Toronto, Ont.—To protect the Canadian Government from loss on the Toronto Harbor dredging contract, the National Surety Company of New York has completed all formalities in connection with the $500,000 bond guaranteeing completion of the contract by Canadian Stewart Co., the contractors. The work will require four years time to complete.

BUILDING

Dundas, Ont.—The John Bertram Sons & Co., will erect an office building immediately at a cost of $30,000.

Brantford, Ont.—The contract for the erection of the new Loew's Theatre in Hamilton has been awarded to P. H. Secord & Son, of this city, at $250,000.

Toronto, Ont.—The Board of Education inspectors report that several public schools require better ventilation and other improvements. It is likely that a number of fans will be installed.

Toronto, Ont.—Messrs. J. & Frank Walsh have purchased a site at 626 King Street, West, and will erect a three storey factory building which can be utilized for light manufacturing.

Magrath, Alta.—Arrangements are being completed for the erection of an elevator here and also one at Raymond and two others at points along the local railway line. Contract for lumber has been let.

Saskatoon, Sask.—A five-storey concrete and brick warehouse, costing in the neighborhood of $125,000 and covering an area of 60 by 124 feet, is to be erected here this spring by a large merchandise company.

INCORPORATIONS

Vancouver Forge Co., has been incorporated at Victoria with a capital of $25,000 to carry on a blacksmith and forge business at Vancouver, B.C.

Sidney Mills Ltd., have been incorporated at Victoria with a capital of $200,000 to operate sawmills, planning mills etc. at Sidney, B.C.

Fort Steele Lumber Co, has been incorporated at Victoria with a capital of $25,000 to carry on business as sawmill proprietors at Fort Steele, B.C.

The Malahat Motor-Ship Co., has been incorporated at Victoria, B.C., with a capital of $100,000 to build and operate motor-ships and steam ships with head office at ancouver, B.C.

The Eburne Clear Cedar Mills, Ltd., has been incorporated at Victoria with a capital of $50,000 to carry on business as shingle manufacturers and take over the B. K. Shingle Co. of Vancouver.

The Air Cooled Burner Co., of Chehalis, Washington, has been authorized to manufacture refuse burners and machinery of all kinds. The capital is $100,000 and office is at Vancouver, B.C.

Akerberg, Thomson & Co., Ltd., has been incorporated at Victoria, B.C., with a capital of $45,000 to carry on the business of machinists, mechanical and electrical engineers at Prince Rupert, B.C.

Vancouver Engineering Works Ltd., has been incorporated at Victoria, B.C., with a capital of $1,000,000 to carry on the business of marine engineers, iron and steel founders, and boiler makers, etc., at Vancouver.

Ladysmith Smelting Corporation Ltd., has been incorporated at Victoria, B.C., with a capital of $1,000,000 to acquire the Tyee Copper Co., and to carry on the business of a smelting and refining company. The head office is at Victoria, B.C.

George W. Cole Ltd., has been incorporated at Ottawa with a capital of $50,000 to carry on business as mechanical engineers, tool makers and founders, etc., at Toronto. The incorporators are George W. Cole, James L. Ross and L. B. Campbell all of Toronto.

The Canadian Wood Molybdenite Co, has been incorporated at Ottawa with a capital of $1,000,000 to carry on the business of mining and manufacturing molybdenite or any other minerals with head office at Ottawa. The incorporators are O. E. Wood, Harvey Fitzsimons and George D. Kelly all of Ottawa.

Canada Lock Joint Pipe Co., has been incorporated at Ottawa with a capital of $40,000 to take over the Canadian interests of the Lock Joint Pipe Co., an American corporation, and to construct part of the pipe line of the Greater Winnipeg Water District The head office is at Winnipeg and the incorporators are Alexander Smith, William Currie and Harold Spencer all of Winnipeg.

CATALOGUES

Power Hammers.—A new pamphlet issued by the United Hammer Co., of Boston, Mass., illustrating and describing the "Fairbanks" power hammers. An illustrated list of parts is included with telegraph code for convenience when ordering parts.

The Independent Pneumatic Tool Co., Chicago, Ill., have issued a new and unusually attractive 94 page catalogue No. 10 bearing the title "Thor" and dealing with an interesting line of pneumatic and electrical tools. The principal features of construction and materials used are described at length together with illustrations of details and sectional views of the air drills and hammers, etc. The various types of tools are all illustrated accompanied by a description while tables are included giving the principal dimensions of each size and work for which each is adapted. Another series of illustrations show the "Thor" pneumatic tools in operation at a number of plants under a variety of conditions. "Universal" electric drills are also described and illustrated while the concluding pages are devoted to particulars of chisels and rivet sets.

Dynamos and Motors.—Pamphlet No. 21-C, recently issued by Bruce Peebles & Co., Ltd., Edinburgh, Scotland, illustrates and describes the "Peebles" self-contained continuous current dynamos and motors. A full specification is included covering these machines which are made in various types such as protected type, semi-enclosed, totally enclosed, mining or pipe ventilated type. The first half is taken up with the specification, while in the latter half very complete lists of output ratings are given for the usual standard voltages, and for every size of machine which they manufacture, separate output ratings being given for each of the five different types enumerated above. To assist intending purchasers in laying out their plant, there are also given two pages of approximate weights and dimensions, while on the last page there is an illustration of two machines mounted together, and arranged as an ordinary motor generator, booster or three-wire balancer. Copies of this pamphlet will be gladly sent to anyone interested.

BOOK REVIEWS

Metal Statistics for 1917.—The tenth annual edition of this useful publication has recently been published by the American Metal Market, New York city. All the tables have been carried forward another year and some new data incorporated, giving the comparative figures a still broader scope. Among the new features introduced is a buyers' directory printed on colored paper. The accuracy of the figures is unquestioned, as the statistics relating to both ferrous and non-ferrous metal production have been obtained from the most reliable sources. It is an extremely useful handbook for buyers and sellers of metals and also plant managers.

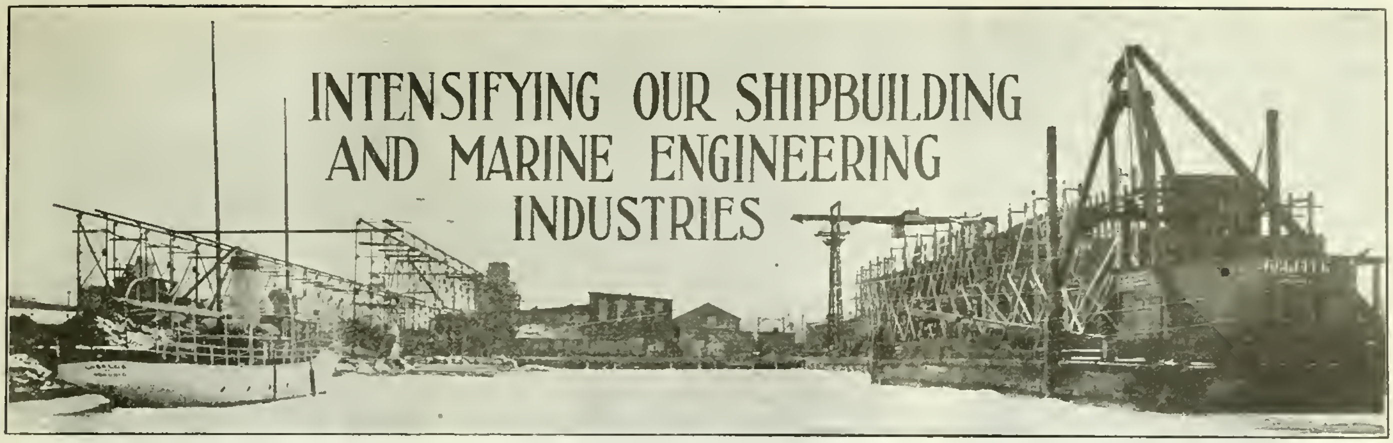
INDEX TO ADVERTISERS



SHIP-BUILDING PLANT OF THE THOR IRONWORKS, TORONTO, LOOKING FROM OFF-SHORE.

By "Drifter"

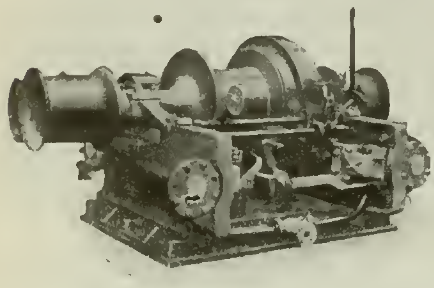
Indications are not wanting that shipbuilding in Canada may not only again flourish, but may quite readily surpass in achievement that of bygone years. Wood ship construction has been revived and promises for a time at least to develop into an industry of considerable proportions. Steel shipbuilding has been given a great impetus, however, and of course to it, more than the other, we look for permanence, and that of a really substantial nature.

THE persistency with which Germany is waging war against the water-borne commerce of the world is certainly not surpassed by her activities in the field, and when results are analysed in each case, and given their proper value relative to the headway we are making towards ultimate and complete victory, it must be admitted that the price being paid in ships on the one hand is equally as costly and as highly undesirable as that being paid in men's lives on the other.

In the past two months, something like one million tons of shipping have fallen victim to mines and submarines. Of itself, this record is sufficiently staggering, although when examined closely, it is seen to be but a more extreme development of a process now many months operative, and which has for its avowed objects either the terrorising of ocean commerce to the point of cessation, or the practical annihilation of same if effort be made to maintain it. The loss of tonnage during February and March of this year through the activities of enemy submarines, and the broadcast sowing of enemy mines on the steamship lanes of the Seven Seas, has been highly abnormal as compared with preceding months of piratical effort, just as much so in that feature as any of the

NORTHERN NAVIGATION CO. STEAMSHIP "NORONIC"— BUILDERS THE WESTERN DRYDOCK & SHIPBUILDING CO., PORT ARTHUR, ONT.

preceding war months were highly abnormal to those of peace-time sea-borne traffic. The situation, in a word, is such as to give concern for the future, not altogether with respect to what may happen if the submarine menace be impossible of early complete control or subjugation, but jointly with, or separate as to these eventualities in the matter of the rehabilitation of the world's shipping tonnage, and more particularly that of British Empire Registry.



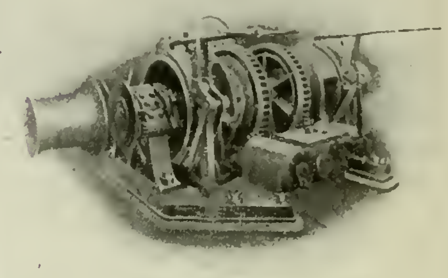
TYPICAL STEAM CARGO WINCH.

Shipping Losses Enormous

At the outbreak of hostilities, world shipping totalled some 50,000,000 tons, of which rather less than half, or, in round figures, 21,000,000 tons was British covered. As might be expected, out of the estimated total vessel losses up to February 1 of this year—2200 ships aggregating $4\frac{1}{4}$ million tons, Great Britain has suffered most, her share being reckoned as little short of $2\frac{3}{4}$ million tons. In view of the fact that peace time losses of ocean carriers attain on the average to probably one per cent. of the whole and that wastage to that extent has been war-time operative, it is but reasonable to conclude that the reduction in world tonnage is even more serious than the figures already quoted.

OIL TANKERS, "ROYALITE," "IOCOLITE," AND "SARNOLITE," BUILT BY THE COLLINGWOOD SHIPBUILDING CO., COLLINGWOOD, ONT.

It may be urged of course that, despite the widespread concentration on naval construction by British shipyards for quite an extended period, enough merchant vessel building was being undertaken to offset the "Act of God" losses; besides, neutral countries, and particularly the United States, had done much in that direction. Be this normal loss compensation as it may, the dearth of ocean carriers has reached an acute stage, and while Britain's shipbuilders are again "on the job," and can be counted on to demonstrate at least their old-time supremacy in tonnage output, irrespective of class or kind, there is room and opportunity for her Colonies and for neutrals as well with the plants and organizations to bear a capacity share in replacing the wastage, and incidentally in the case of the Colonies of aiding also in sweeping enemy marauders from the seas, and restoring the merited freedom of the latter as early as possible.



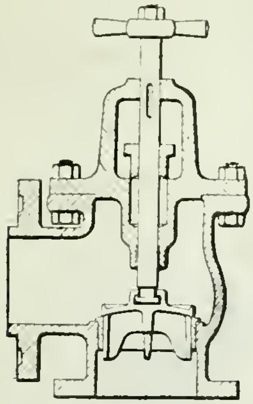
TYPICAL STEAM WINDLASS.

Our Call to Shipbuilding

To Canada then the call has come to participate in the restoration of the Empire Merchant Service, and, judging from the enthusiastic response already given, there is little doubt but that results will compare quite favorably with those achieved in the departments of men, money, and munitions. The work being undertaken has a twofold object—

625-FT. FREIGHTER "W. GRANT MORDEN" BEING LAUNCHED FROM THE YARD OF THE WESTERN DRYDOCK & SHIPBUILDING CO., PORT ARTHUR, ONT.

the combating of enemy submarine activity and mine sowing effort, and the placing in service of a fleet of freighters to more or less standard design from keel to truck, and of carrying capacities commensurate with shipyard location and facilities. Notwithstanding the high cost of materials entering into vessel construction meantime—steel, finished and semi-finished, also the irksomeness of the steel mill situation as regards delivery, excellent progress is being made on hull, propelling machinery, and general outfit equipment, by those of our shipyards whose establishment and proved competency belongs to years



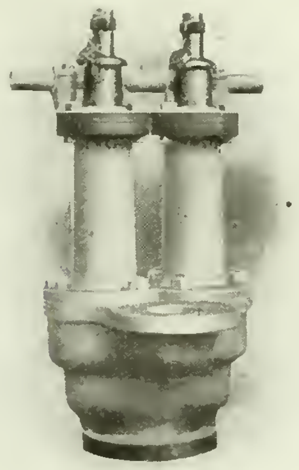
ANGLE TYPE CIRCULATING PUMP DISCHARGE VALVE

more or less well removed from the meantime emergency.

Our Past Accomplishment

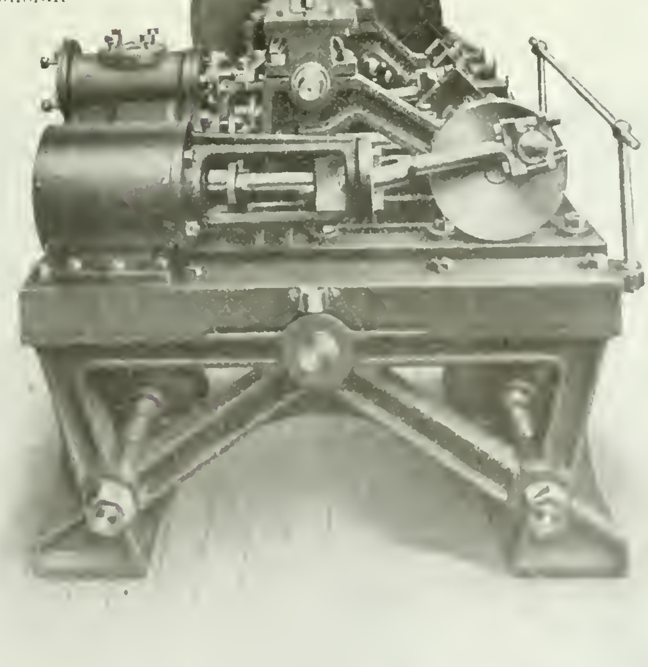
To those unfamiliar with what has been accomplished by Canadian steel shipbuilding plants in previous years, the variety type vessel illustrations herewith may prove of rather more than passing interest, and when account is taken of the climatic and other disabilities under which those responsible for the administration of the various enterprises have labored in the past, considerable surprise may be manifested that so much—both in quality and quantity, has been accomplished. The handicap of climate—long and severe winters in the regions of our lakes, Eastern waterways and ocean shores, has not, however, been the most serious in restricting shipbuilding operations, although due to the hitherto fluctuating nature of the demand for new construction, and its general sparseness in volume tonnage and individual vessel constituent, little effort has been made to reduce the climatic disability to the extent that building as well as fabricating operations could proceed uninterruptedly the year round.

Even in the Old Country, where the winters are less prolonged and correspondingly less severe, roofed-over sheds amply equipped with natural and artificial lighting facilities, lifting and



MARINE TYPE TWIN SAFETY VALVE.

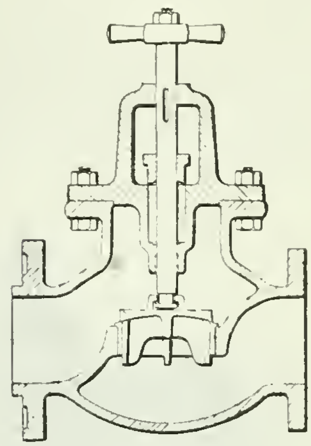
transportation conveniences are provided whereby the employees go about their work under conditions giving the maximum degree of both comfort and safety. There is of course the further gain, in that greater expedition is possible in the matter of output. To the writer's knowledge, only one Canadian shipyard, that of Canadian-Vickers, Montreal, has its shipbuilding berths shed-equipped, although we shall be much surprised if quite a large percentage of the new shipyards now being established, as well as the other meantime going concerns, do not include in their projected or immediate future plans some such indispensable aid, so as to more effectively embrace the unusual opportunity now offering, and thereby make a material contribution to their world-competitive status.



HORIZONTAL TYPE STEAM STEERING ENGINE

Making Shipbuilding a Staple Industry

The existing situation, and undoubtedly that of the coming years demand that Canada enter more largely into the business of shipbuilding. Preceding the war, the stumbling block to our development of the industry was, as already stated in connection with the shipbuilding berth matter, both the lack and uncertainty of demand for new construction, due wholly to European competition. From the loss figures previously

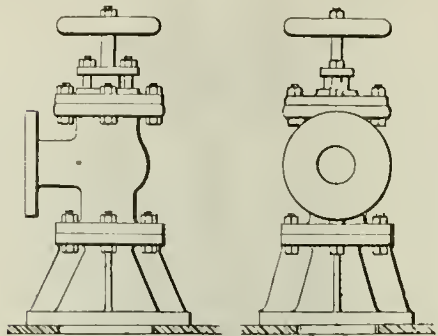


GLOBE TYPE CIRCULATING PUMP DISCHARGE VALVE.

quoted it will be readily apparent that the demand is now not only of extraordinary proportions but of the most imperative nature; and must needs be satisfied. While, therefore, no stone should be left unturned to make our entry one of urgent and immediate concern, let us see to it, that we do so with a due appreciation of the various factors operative in favor of or against positive success and substantial permanency.

Class of Labor an Essential

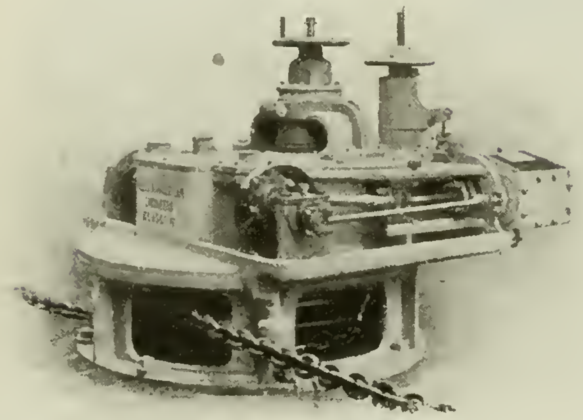
Class and cost of labor—not necessarily that pertaining to shipbuilding only, have militated in considerable degree against our competitive ability in a world sense. Due to the intermittent vessel demand, however, it has been wholly impossible for our shipyards to maintain either an expert staff or more than a mere handful of mechanics trained to the work of shipbuilding. As a result, with little permanency of employment in sight, men drafted, as we might say from the "four winds," with neither stake in the shipyard nor in the citizenship of its town location, could not on occasion be expected to produce results commensurate with those of their fellows on say the Clyde at Belfast, on the Tyne, Tees or Humber, in Great Britain, where employment in the various departments of shipcraft has been and is to all intents and purposes of a quite permanent nature. Under the latter circumstance the "bird of passage" tendency gives place to more or less permanence of residence. Again, even where we have in the past requisitioned unskilled local help, the practical training process has been largely unsatisfactory on account of lack of technical training facilities, and where these have been available, there has not infrequently been an insufficiency of elementary or day school education to enable the worker to appropriate the technical instruction offered. While, therefore, it will doubtless be possible to import, so to speak, not only a number of men skilled in directing shipbuilding operations in detail, and a fair muster of others with more or less experience of the everyday routine of vessel construction, it will be an absolute necessity, and more so as regards new enterprises that a service enlistment proposition be made our young men which will make it worth their while to enter shipbuilding and marine engineering—one branch or another, as a life craft or profession. To ensure success in this respect, among the other plans and projects being devised and developed, the plant executive, as is done in Great Britain, must arrange to provide instruction courses, whereby what would otherwise indicate but a year-in and year-out monotonous routine leading to nowhere in particular, a lad's interest in his work and his ambition to rise to a place of prominence in his profession would receive the necessary stimulus. With the prospect of at least a handful of years of boom shipbuilding ahead, and a fair chance of the industry finding a permanent establishment, of scope hitherto unapproached, schemes for developing the quality of help should on no consideration be overlooked, be wilfully omitted, or be marked by indifference.



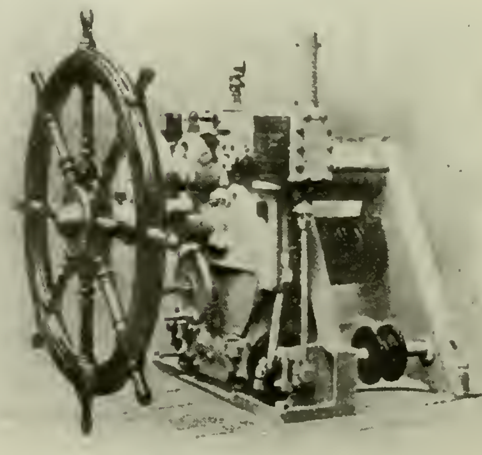
TYPICAL SEA SUCTION VALVE.

Cost of Labor

Aside from the cost of material entering into ship construction, no other factor has probably contributed to the lack of opportunity for vessel building in Canada so much as that of labor cost. For the like reason shipbuilding in the United States was in pre war days hopelessly outclassed as against European enterprise. Labor is a primary essential in every business worthy the name, and while its individual productive capacity may, as we have seen, leave little scope for sifting out and replacement, it is well-known that its assessed value, which must often be accepted without demur, is in many instances altogether out of proportion to its output value, and of course in a direction quite foreign to the stimula-



HORIZONTAL TYPE STEAM STEERING ENGINE.

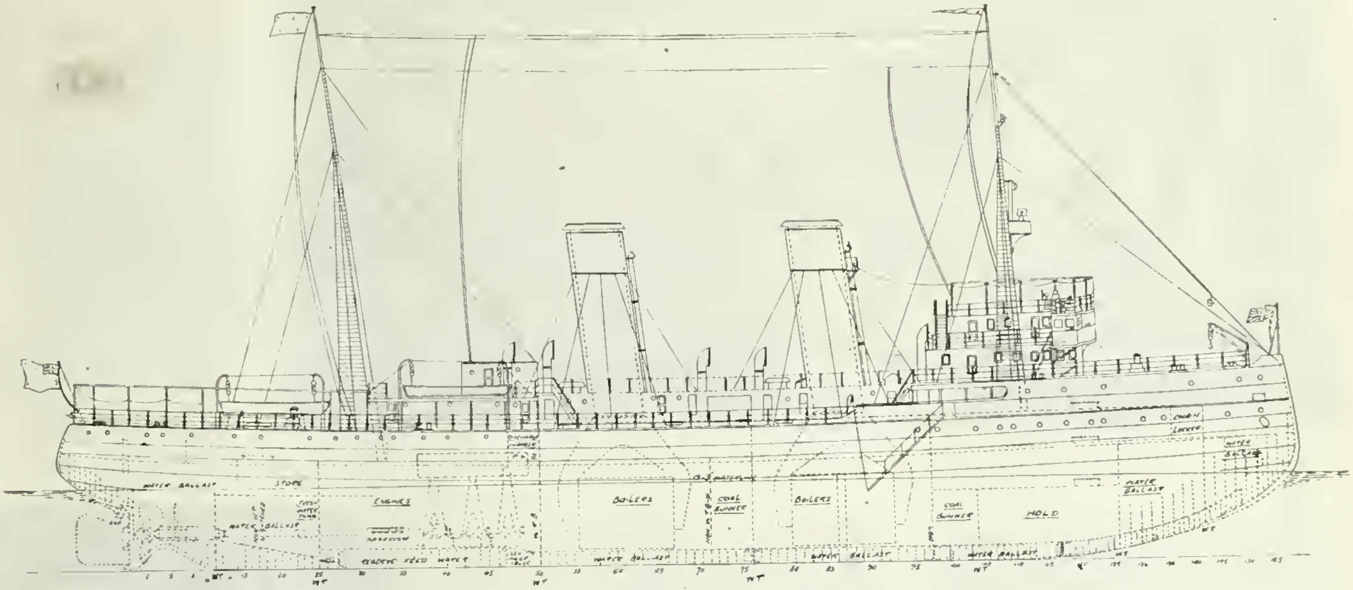


VERTICAL TYPE STEAM STEERING ENGINE.

GLOBE TYPE—AIR PUMP DISCHARGE VALVES.—ANGLE TYPE.

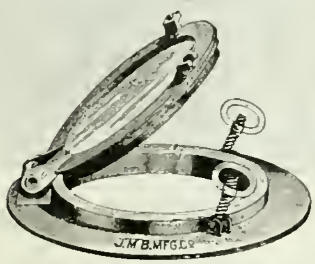
TYPICAL BOILER FEED PUMP.

tion of competition in the world's ship market. We will abstain from making direct comparison between shipyard employees wages in Britain and those in



ICE-BREAKER "J. D. HAZEN," BUILT BY CANADIAN-VICKERS, LTD., MONTREAL.

Canada ante-dating the war, believing that no useful purpose would now be served if we did so, for the reason that

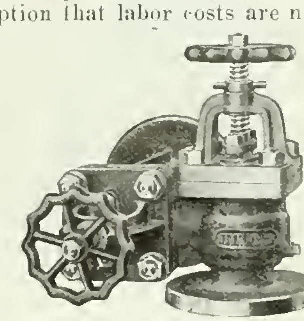


SHIP'S LIGHTS.

a cleavage has taken place as a result of the varied war activities. It is our opinion that the degree of wage uniformity in Great Britain and Canada now prevailing will be little disturbed when munitions and other forms of war effort cease. Suffice it perhaps to say here, that previous to the opening of hostilities, the difference between wages paid in Great Britain and those in Canada was in itself sufficient to place Canadian shipbuilders well beyond the pale of being serious competitors in the world ship market. Labor quality and labor quantity will, it seems to writer, exert a more marked influence on the development, continuity, and permanence of Canada's shipbuilding industry during what may be termed its crucial or testing period, i.e. the next decade, than will any question of labor cost.

Material Cost

The question of cost of materials entering into shipbuilding and marine engineering has a many-sided aspect, and it is just possible that investigation even in a more or less superficial and general way of the more important considerations requiring attention may be of interest and profitable when studied from say a comparative viewpoint. On the assumption that labor costs are now to all



"BEAVER" COMBINED STOP AND CHECK VALVE.

intents and purposes equalized, and taking the cost of material pure and simple

IRON WORKERS SHED, CANADIAN-VICKERS, LTD., MONTREAL.

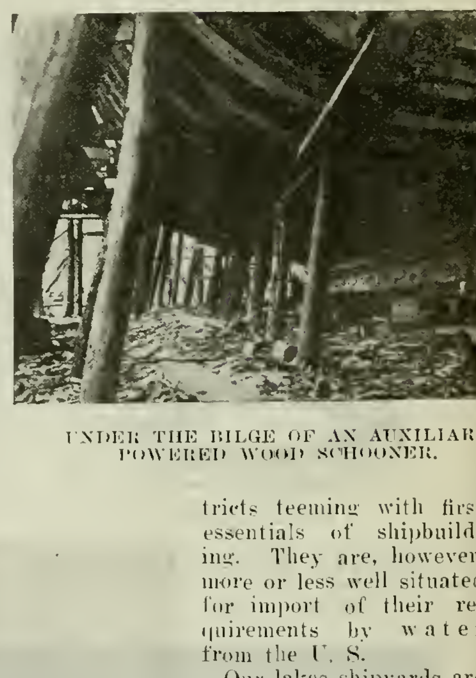
CAULKING THE MAIN DECK OF 200 FT. O.A. AUXILIARY POWERED WOOD SCHOONERS.

as between Great Britain and Canada, what do we find? Materials of construction, whether for vessel hull, or miscellaneous equipment have been and still are for the most part imported by Canadian shipbuilders and marine engineers. Great Britain on the other hand is practically self-sufficient for her shipbuilding requirements, and in the light of her output capacity this is saying a great deal.

It has been urged that as in labor costs so in those of material, there is meantime, little, if any, difference in the price British shipbuilders are called upon to pay for, say steel, a circumstance due of course to the abnormal demand for that material for munition purposes as well as for shipbuilding, and to her having to supplement her domestic production by import as in our case. It should, however, be borne in mind that the situation in Britain is not only highly abnormal these days, but of quite a temporary nature, and that so far as Canadian competition is concerned, the conditions we will have to meet when the demand for munitions steel, etc., ceases, will be approximately those of Britain's pre-war days, and with steel of her own manufacture. This, needless to say, will be more largely and readily available, because of the additional domestic productive capacity created by the war needs. A readjustment of steel prices favorable to British shipbuilders may reasonably be looked for following the cessation of hostilities.

Plant Locations in Canada

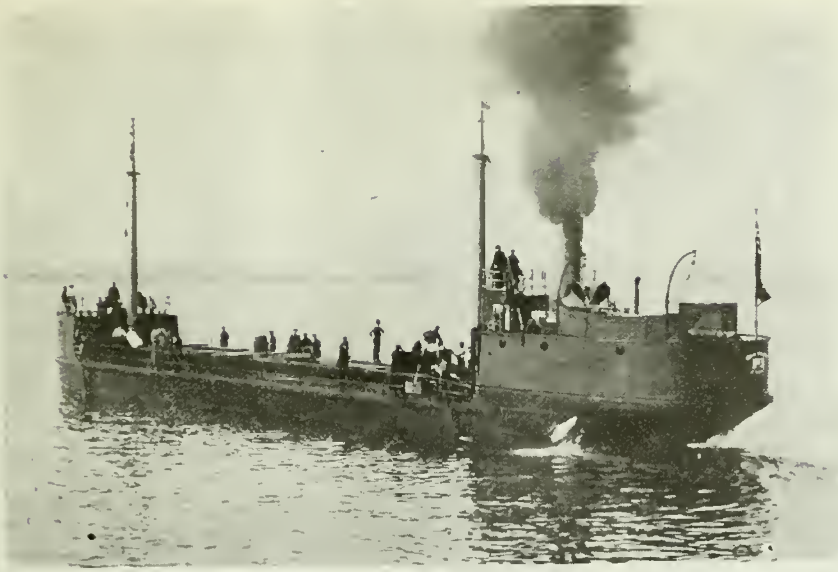
Of our present established group of shipyards, it may be said that, with the exception of the recently equipped plant of the Nova Scotia Steel & Coal Co., at New Glasgow, N.S., none of the others are in any sense close to the sources from which they draw their raw, semi-finished and finished material. Shipyard location in Canada, while influenced to some extent by its relative bearing to supply sources, has been determined largely by other considerations. Our lakes and Pacific Coast shipyards cannot by any stretch of imagination be said to have been established in the heart of districts teeming with first essentials of shipbuilding. They are, however, more or less well situated for import of their requirements by water from the U. S.



UNDER THE BILGE OF AN AUXILIARY POWERED WOOD SCHOONER.

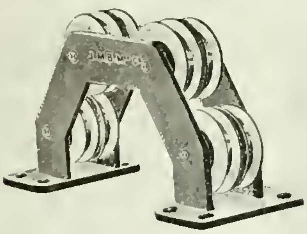
Our lakes shipyards are handicapped when it comes to building even medium tonnage vessels for ocean service by reason of the insufficiency of canal accommodation via Montreal and the St. Lawrence to the sea, and while even now, on the upper lakes at least, freight and passenger ships of over 600 ft. in length have been built and are building, their service scope is restricted, with the result that the construction demand is quite intermittent. No limit as to vessel size is imposed on our Pacific Coast builders, yet the lack of proximity to the sources of supplies contributes to about the same ultimate outcome in progressive competi-

AUXILIARY POWERED SCHOONERS OF WOOD, 200 FT. OVER-ALL LENGTH, BUILDING AT NORTH VANCOUVER, B.C.



ONE OF THREE LIGHTERS BUILT BY POLSON IRON WORKS, TORONTO, FOR CANADIAN GOVERNMENT SERVICE ON HUDSON BAY.

tive development as does that of our lakes plants. In either case, however, the shipyards established are a necessity, if now solely for new construction, then for repairs and overhaul, and it may be accepted that the

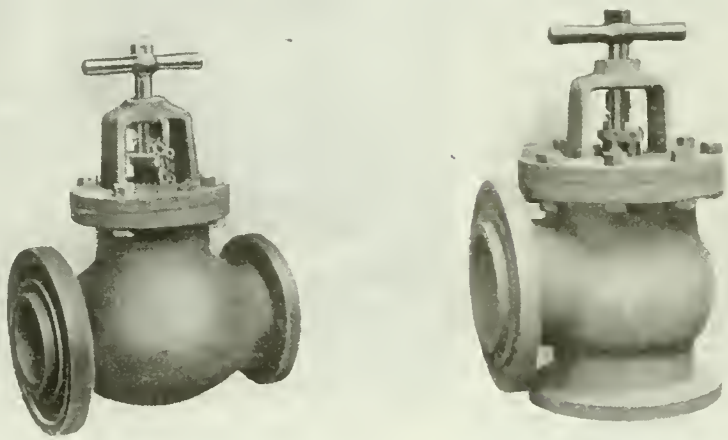


GUIDE SHEAVES FOR SHIP'S TELEGRAPHS.

plants at Toronto, Collingwood, Port Arthur and on the coast of British Columbia have been installed at strategical points, to undertake such work promptly and effectively. That they have been doing so profitably alike to themselves and vessel owner is well-known, and in the matter of building canal size craft—260 feet over-all length, they have exhibited commendable enterprise, and have been rewarded with well deserved success.

Plant Locations in Great Britain

In Britain, so far as rivers go, comparatively, there is nothing spectacular about the Clyde, Mersey, Tyne, Tees, Humber, etc. All of them are comparatively modest in length, navigable waterway, and otherwise attractiveness, yet they have appealed to shipbuilders, and have become famous on that account. Not one of them is a ghost, however, of its former self, and altogether to their specific location and possibilities have the sweeping changes and costly developments been attributable. Their location has given them importance because of their running through the heart of districts abounding with just such essentials of shipbuilding, engineering, and general manufacturing as permit of their ready appropriation, reduction, fabrication and transportation to world markets made and in the making.



CIRCULATING PUMP DISCHARGE VALVES.

Globe Type. Angle Type.

If, then the shipbuilding industry in Canada is to have competitive rank with that of Great Britain, it surely becomes absolutely necessary that plant establishment and development should have careful consideration. In the writer's opinion shipbuilding for ocean service is only competitively possible on our Eastern shores as far inland as the city of Montreal. With this statement, there will be found few to disagree. Montreal is the head of ocean navigation for Eastern Canada, besides being the big port of the whole Dominion. Even in her case it may be said in passing that convenience to the sources of raw materials in [illegible] shipbuilding and marine engineering is not as desirable as could have been wished for, nevertheless, by virtue of her ocean navigation leadship, and her multiplicity of metal-working and kindred industries, more or less of which are necessary feeders for shipbuilding and marine engineering on a large scale, she doubtless may be expect-

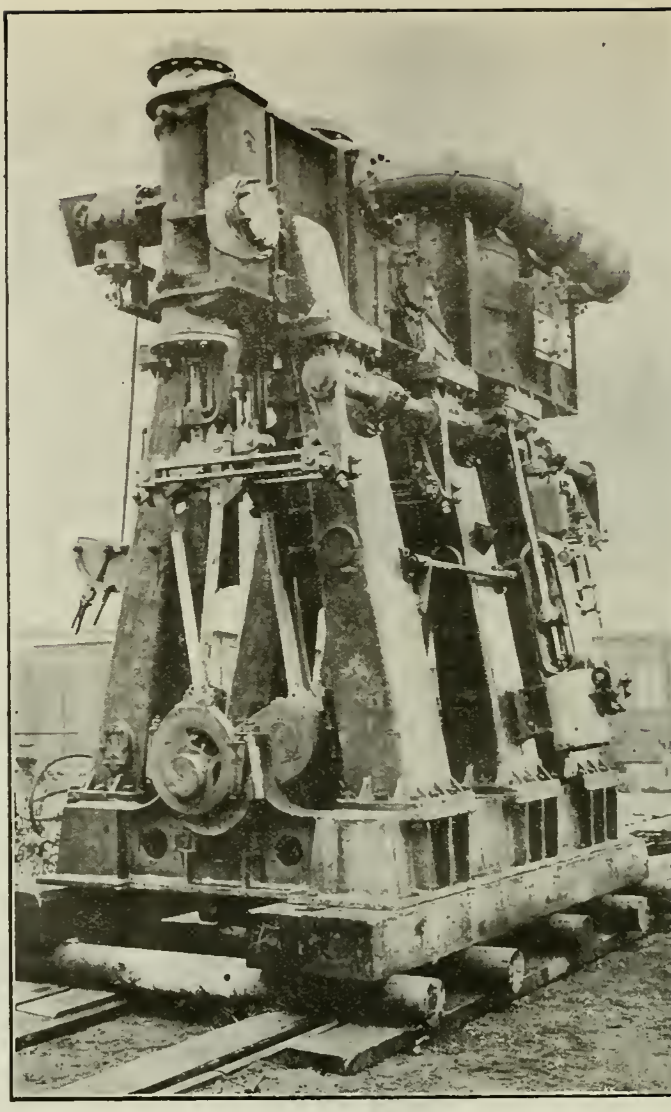
BUCKET DREDGES BUILT FOR THE CANADIAN GOVERNMENT BY THE COLLINGWOOD SHIPBUILDING CO., COLLINGWOOD, ONT.

ed to make a substantial and successful bid for vessel contracts against the world in the coming time.

The meantime centre of Canadian shipbuilding and marine engineering effort is the plant of Canadian-Vickers, Ltd., of Montreal, the volume and variety of work under construction there easily surpassing that being undertaken elsewhere in the Dominion. In addition, it has been constituted the distributing centre for numerous marine engineering contracts, the filling of which is being expeditiously carried out by well known Canadian engine and boiler builders over a comparatively wide area.

Shipbuilding Plants Projected

Since a full realization of the opportunities afforded us of taking a hand in the restoration of our Empire shipping has been grasped, many shipbuilding concerns have been incorporated, and not a few have already taken the preliminary steps of securing expert advice, and examining suitable sites. As bearing out what has been already indicated, it is noteworthy that without exception possibly, investigation is being made of locations on or adjacent to the Atlantic seaboard. Private enterprise, as might be expected, is being substantially backed and encouraged by a number of municipalities, prominent among which may be noted Three Rivers, Que.; St. John, N.B.; Halifax, N.S., and Sydney, N.S. Provincial Government aid is not lacking either, for as recently as March 23, a Bill, entitled "An Act for the Encouragement of Shipbuilding Within the Province," was introduced in the House of Assembly, Halifax, N.S., by Premier Murray. The Bill authorizes the appointment by the Governor-in-Council of a Commission, to be known as the Shipbuilding Commission, to consist of five commissioners and a secretary. The duties of the Commission are to investigate the facilities existing within the province for the building of ships and the manufacturing industries incidental thereto, and to make suggestions tending to the adoption of practical rules and regulations to encourage the utilization of all natural and other resources calculated to facilitate the development of the shipbuilding industry within the province. The Commission is empowered to engage whatever technical or expert assistance is necessary.



TRIPLE EXPANSION JET CONDENSING PROPELLING ENGINES OF 900 I.H.P. FOR CANADIAN GOVERNMENT BUOY STEAMER "GRENVILLE."

The Bill provides that the Commission may, by Order of the Governor-in-Council, be created a body corporate, and when so created shall have power:—

To construct, purchase, lease or otherwise acquire ships and shares in ships, and to equip, maintain and operate any ships so acquired.

To establish, equip, maintain and operate any manufacturing plant for the manufacturing of ships of iron, or steel, or wood, or any combination of metals of like character.

To enter into any contracts with any company or corporation for the acquisition of any shipbuilding plant, and to acquire and exercise the power, rights, franchise and privileges, and assume the

CAR FERRY "ONTARIO NO. 2," BUILT BY POLSON IRON WORKS, TORONTO.

ELECTRICALLY OPERATED GANTRY AND SHIP BUILDING BERTH AT THOR IRON WORKS, TORONTO.

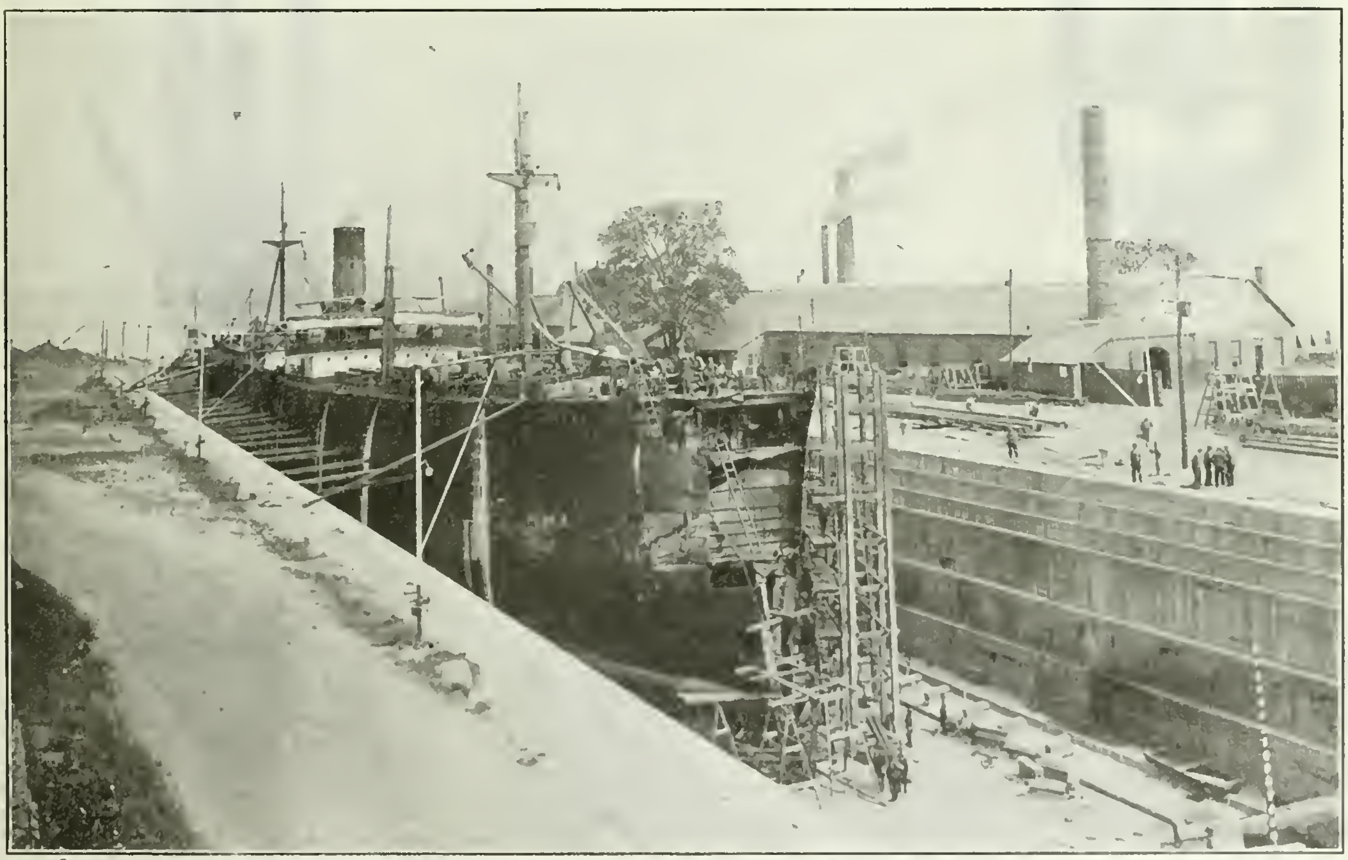
obligations of any company or corporation whose undertaking is purchased, leased or otherwise acquired by the commission.

To promote any company or companies for the purpose of acquiring all or any property of any company, or for any other purpose which may seem directly or indirectly calculated to assist in the development of shipbuilding industries within the province.

To purchase, lease or otherwise acquire any real and personal property, and any right or privilege which the commission may think necessary or convenient.

A number of other objects and powers are enumerated. The Bill then provides the usual pro forma powers and authority, by the Governor-in-Council, to issue bonds, expropriate lands and to grant Crown Lands.

The Governor-in-Council is authorized to raise by loan on the credit of the province the sum of $2,000,000, and the interest raised by the sale of Nova Scotia debentures or consolidated stock is to be paid into the Provincial Treasury and

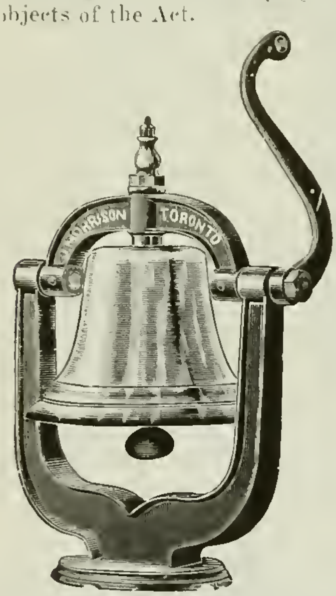


GRAVING DOCK AT LEVIS, QUE., WITH FREIGHTER UNDER REPAIR. DAVIE SHIPBUILDING & REPAIR CO

NORTHERN NAVIGATION CO. STEAMSHIP "HAMONIC," BUILT AT COLLINGWOOD, ONT.

used for the following variety purposes:

Payment of any expenses incurred by the Commission in the carrying out of the objects of the Act.



SHIP'S BELL.

Any subsidies granted by the Governor-in-Council to the Commission, or to any company engaged in the building, equipment or operation of ships.

Payment of obligations which the Commission may incur in the carrying out of its objects.

The Governor-in-Council is authorized to enter into any contract for the development of the shipbuilding industry in the province, and to grant subsidies to the Commission or any shipbuilding company within the province.

Shipbuilding Plant at Newcastle, N.B.

Within the last few days advices reached us that the International Shipbuilding Corporation, recently formed with a capital of $2,000,000, had decided to locate a plant at Newcastle, N.B., the site determined upon having been that on which wooden ships were built when that feature of the industry flourished in the Maritime Provinces. In addition to a water frontage of some 1,600 feet, and a depth of water available to float ships of at least 10,000 tons, the town of Newcastle is admirably located for procuring at reasonable cost the bulk of the lumber entering in ship construction and equipment. Not only so, within its borders and quite adjacent are several lumber mills, etc. The layout of the plant is in the hands of a naval architect of Boston, Mass., and among those interested in the undertaking are E. A. McCurdy and L. H. McNaught, of the town of Newcastle. The latter is managing director of the Maritime Foundry & Machine Works there, which enter-

"HIGGINSON" NON-TOPPLING BLOCKS FOR LIFEBOATS.

prise, it is understood, will be absorbed by the shipbuilding corporation.

Shipbuilding at New Glasgow, N.S.

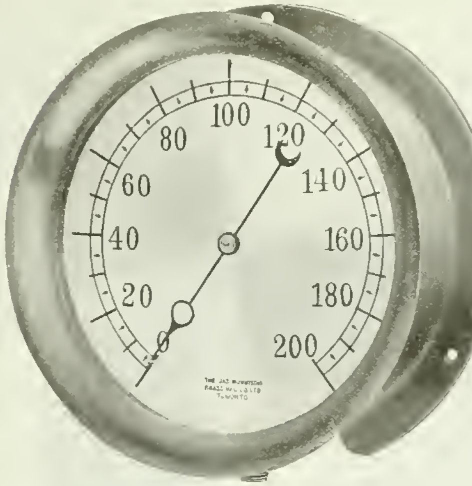
As is well known, the Nova Scotia Steel & Coal Co., New Glasgow, N.S., in view of the shortage of "bottoms" a year ago, and the effect it was beginning to exert on the various steel producing activities at their Newfoundland, Sydney Mines, and New Glasgow plants, decided to try the experiment of building at least one vessel, the design, constructional, and equipment features of which would meet the requirements of their own or that of any manner of freight-carrying service. Work on this ship, as also on her propelling and auxiliary ma-

24 INCH HYDRAULIC SUCTION DREDGE BUILT BY POLSON IRON WORKS, TORONTO, FOR HARBOR DEVELOPMENT WORK.

chinery, is now well advanced, and is being pushed forward with the utmost despatch, and her launch, which will be a red letter day, not only in the town of New Glasgow, but throughout the Maritime Provinces generally, is scheduled to take place on an early date. The building of this vessel is pioneer work in every sense of the term, as she will not only be the first steel ocean-going freighter to be constructed in our seacoast provinces, but in the matter of her propelling machinery she will evidence a forward step so far as Canada is concerned in the sphere of marine engineering. In a word, she will be propelled by De Laval impulse type steam turbines of 1,000 B.H.P.

We were unfortunately unable to have an illustration of the vessel appear in this issue; however, from a perusal of the accompanying specification covering her principal features, some fair appreciation of the task that the management of "Scotia" set itself will be realized, and the more so when it is stated that the whole enterprise began at rock-bottom, so to speak—selecting, clearing, and preparing a building site.

The principal dimensions of the vessel are as follows:—Length over-all, 230 ft.; length between perpendiculars, 220 ft.; breadth molded, 35 ft.; depth molded, 20 ft.; load draft, 17 ft.; carrying capacity, 1,900 tons; displacement loaded, 2,870 tons; speed, 10 knots. The vessel is being built to Lloyd's 100 A1 class. She is of the single deck type.

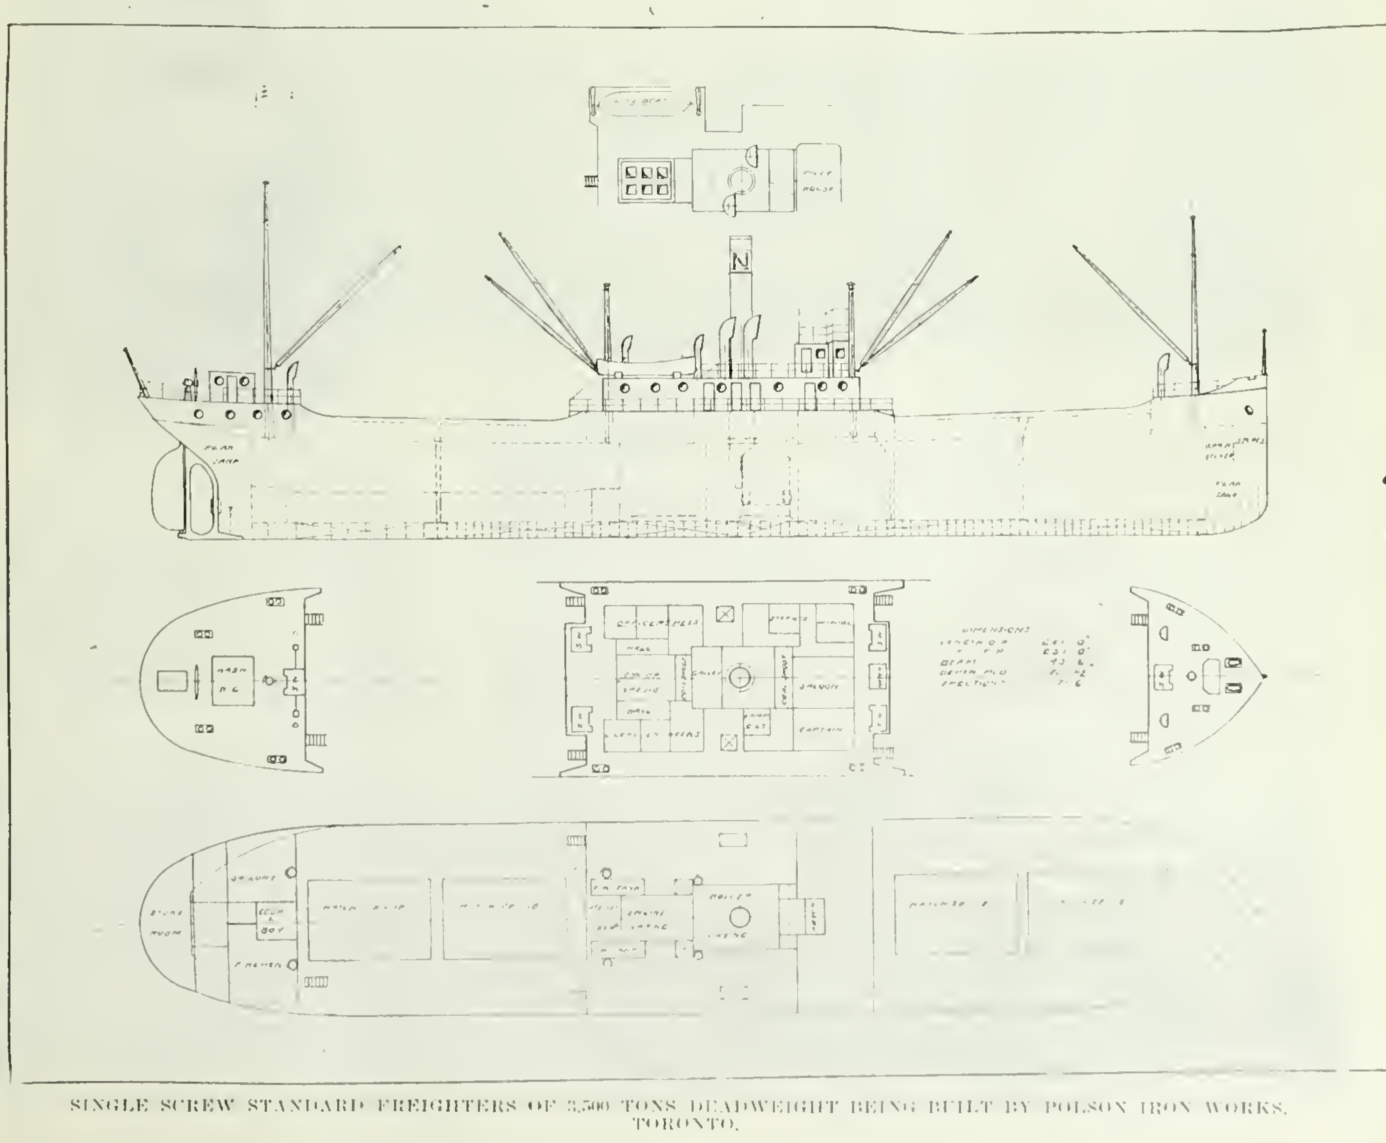


STEAM PRESSURE GAUGE.

with bridge and topgallant forecastle, the propelling machinery being placed amidships. The forecastle deck is 26 feet long, while the length of the bridge deck is 56 feet. She is provided with complete double bottom, 34 inches deep, of the cellular type, constructed with solid and open floors, having centre division and two longitudinal girders on each side, running the entire length. The space between the bottoms is arranged for water ballast, so that a desired draft can be obtained when the ship is sailing without cargo.

Four water-tight bulkheads, extending to the main deck, divide the cargo holds, of which there are two, from the machinery space and peaks. The forward hold has two hatchways, each 28 ft. 9 in. long, by 19 ft. wide, one hatchway of the same dimensions being fitted to the after-hold. Two steel masts are fitted, each about 55 ft. high above the main deck, and for the handling of cargo the foremast will be provided with two derricks, while the mainmast will have one, each derrick having a lifting capacity of three tons. For this purpose deck winches of the latest type are being installed.

The frames are spaced 23 inches apart from the stern post to just abaft the collision bulkhead, where they are spaced 20 inches, and, to cope with ice conditions, the spacing in the forepeak is reduced to 17 inches, with heavy side plating at the load water line. This, together with panting beams and string-



SINGLE SCREW STANDARD FREIGHTERS OF 3,500 TONS DEADWEIGHT BEING BUILT BY POLSON IRON WORKS, TORONTO.

a speed of 4,000 r.p.m. This is reduced to 80 r.p.m. at the propeller through two sets of reduction gears. The gears are lubricated with oil from a tank placed on the main deck. A separate pump is used to draw the oil from gear casings and deliver to this tank through a water cooler. There is also a separate pump to supply cooling water. Air and circulating pumps are driven by a separate engine capable of maintaining a vacuum of 28½ inches in the condenser with the engines developing full power. There is the usual installation of ballast, general purpose feed and bilge pumps.

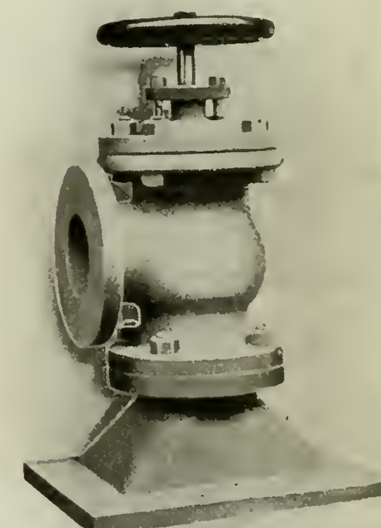
Steam is furnished by two Scotch type marine boilers, each 11 ft. 6 in. in diameter and 11 ft. 6 in. long, their working pressure being 185 lbs. per sq. inch. The steam steering engine is placed on the main deck aft, with chain drum extending through the bridge bulkhead. The winches, three in number, are of the usual type, and have been designed and built by the Pictou Foundry & Machine Co., Pictou, N.S. The pro-

C.P.R. WESTERN LAKE STEAMER "BONNINGTON," BUILT BY POLSON IRON WORKS, TORONTO.

ers, makes the vessel exceptionally strong at the forward end. In the forehold, at a point between the two hatchways, a deep web and arch frame has been fitted 30 inches wide, with large brackets to the deck, thus eliminating stanchions and leaving the hold clear of obstructions.

At the fore end of the bridge is a deck house containing, on the bridge deck level, the captain's room, one spare room, steward's room, dining room, pantry, stores, and other offices. Above this is the chart room, pilot house, and navigating bridge. Abaft of the captain's quarters, the chief officer and chief engineer, together with the junior officers and engineers are housed, as is also the cook. Accommodation in the forecastle is provided for five seamen and four firemen. Here also is located the crew's wash room, lamp room and dunnage room.

The propelling machinery is being supplied by the De Laval Steam Turbine Co., Trenton, N.J., and consists of an impulse type steam turbine capable of developing 1,000 b.h.p. when running at

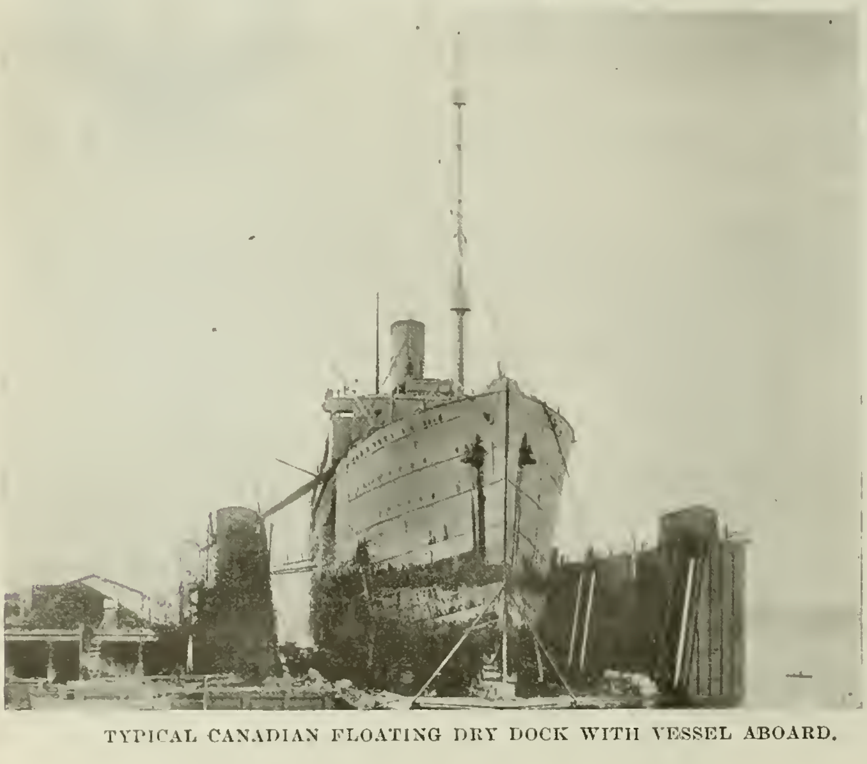


TYPICAL SEA SUCTION VALVE.

pelling engines are the first of this type to be placed on any ship in Canada. They are also the first set of De Laval turbines to be placed on any ship, although since receiving the "Scotia" contract, the makers have secured orders for thirty of a similar type to be placed in vessels now building in the United States.

Shipbuilding in Wood

Enough has probably been said to indicate that the future development of the Canadian shipbuilding industry from a world competitive standpoint will be largely confined to our waterway and ocean shore territory from Montreal eastward. We do not, of course, lose sight of the fact that our inland lake and Pacific Coast shipyards will continue to contribute quite materially to our total annual outputs as they have done in the past, nor do we fail to recognize how essential they are for repairs, dockings, and overhauls, at such



TYPICAL CANADIAN FLOATING DRY DOCK WITH VESSEL ABOARD.

sheltered and traffic strategical points as Toronto, Kingston, Collingwood, Port Dalhousie, Welland, Port Arthur, Victoria, Vancouver, Esquimalt and Prince Rupert.

Shipbuilding is booming on our Pacific Coast, as perhaps never before in its history, both wood and iron craft of hefty tonnages being under construction and not a few, particularly the auxiliary powered wooden schooner type, being already completed or approaching that stage. Shipyards on the Pacific Coast are admirably located for wood construction, lumber of every class and kind being abundant and readily convenient. Much enterprise has been shown in tackling this work of building substantial ocean-going craft in wood, and the success of the effort not only on our Pacific shores, but on those of the broad Atlantic, is no less commendable than that in evidence relative to steel construction. Wood shipbuilding, once our pride, has, in this war-created emergency, been revived, and to an extent, little, if any, short of its most palmy days in our midst. It has temporarily stopped the gap caused by delayed new construction in steel, through the abnormal demand for that commodity for other purposes, etc. Ton for ton, wood construction is cheaper, and while, dur-

TYPICAL CANADIAN FLOATING DRYDOCK WITH TWO SECTIONS OPERATING INDEPENDENTLY.

ing the course of the war, with the continued activity of enemy submarines and the risks of colliding with mines, wooden craft are no doubt more vulnerable, the fact remains that their cost as compared with steel vessels, is less burdensome should disaster supervene. Chief among the Pacific Coast firms building wooden craft on a large scale are the Cameron Genoa Mills Shipbuilders, Victoria, the Wallace Shipyards, North Vancouver, and John Coughlan & Sons, Vancouver.

Shipbuilding Industry Auxiliaries

Shipbuilding, when the construction of high-class liners is involved, may be said to be altogether cosmopolitan, in that hardly any trade or industry may be found unassociated with it. In degree only is this less true of craft with more modest titles—tramps. Among the illustrations accompanying this article, will be found a fair representation of accessory equipment common to deep sea vessels, whether for salt or fresh water service, passenger or freight trade. The examples of vessel type—there is no lack of variety, are in every case products of Canadian shipyards, and with a few exceptions the auxiliary machinery and accessory equipment are also of Canadian manufacture. The exceptions, we may say, are representative of British manufacture, some of which have in the past found a place aboard Dominion-built ships.

As bearing out the statement in the opening sentence of the above paragraph, shipbuilding may be said to create opportunity and broaden the scope of metal working and kindred manufacturing plants, irrespective of their being large or small. A few of the requirements follow:—Brass, iron and steel castings; ship and engine forgings, heavy and light; deck and hold stanchions; ship plate and shape mills; sheet iron and tinplate work; chain—anchor and derrick; rope—hemp, Manila, wire, for mooring and hoisting; anchors, lamps, radiators, wash basins, bath tubs, water closets, furniture and furnishings; lifeboats, lifebelts, lifebuoys, electric wiring, charts, compasses and telegraphs; hand and steam steering gears; steam and hand winches, windlasses and capstans; ash hoisting engines and ash buckets, firing tools, chequered plating, sparred gratings or grills, and hand railing; safety, stop, and throttle valves; feed check, sea suction and discharge valves; water gauge fittings, pressure and vacuum gauges, jointing material and gaskets; boiler, pipe, and cylinder lagging; directing or distributing boxes; feed, bilge, fire and deck pumps; propellers; shaft, eccentric, piston and connecting rod forgings; cylinder drain and small pet cocks; relief valves; dynamo engines and dynamos; motors; forced draft and ventilating fans and engines; oilers; chain blocks; rope blocks; copper and brass piping; indicators, indicator cocks and piping; eyebolts, shackles, clocks, galley and refrigeration equipment, ship chandlery, general, etc.

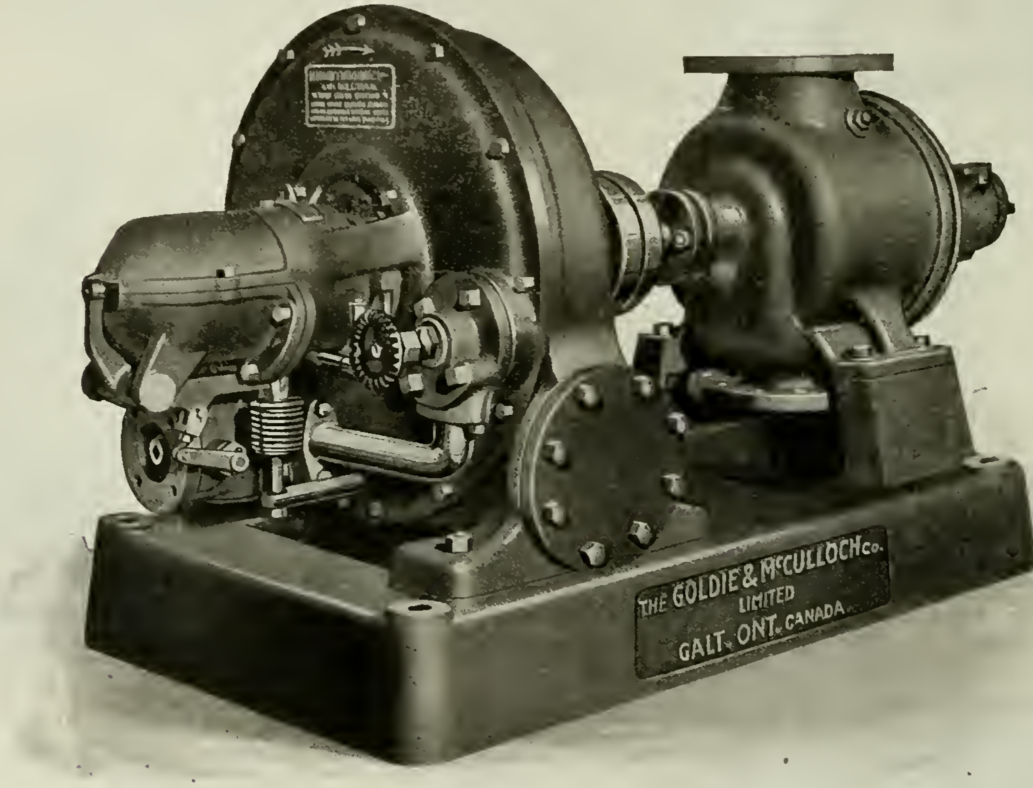
TRIPLE EXPANSION ENGINES OF THE NORTHERN NAVIGATION CO. S.S. "HAMONIC." BUILDERS THE COLLINGWOOD SHIPBUILDING CO.

Convenience in procuring equipment as above detailed is by no means unimportant, although in the establishment of new shipbuilding plants it is not always possible to have the various trades represented within ready call. Judging from personal observation, and having the various auxiliaries and accessories enumerated in mind, such centres as Montreal, Que.; Halifax, N.S., and St. John, N.B., would be ideal for a shipbuilding and marine engineering plant installation, other conditions being

GENERAL VIEW OF PLANT OF THE MONTREAL DRYDOCK CO.



TURBINE DRIVEN CENTRIFUGAL PUMP FOR BILGE, BALLAST OR CIRCULATING PURPOSES.

equally satisfactory, of course. In each of these cities, small engineering, blacksmithing, and foundry enterprises abound, as do also agents with warehouse accommodation for stocking standard marine supplies. A shipyard unless surrounded by quite a coterie of general providers as indicated is both isolated and handicapped, and while such a condition may be altogether beyond control, an obstacle of no mean proportions is always in evidence to restrict progress and expansion, no matter how ideal be the water front facilities.

Shipbuilders and marine engineers welcome the help arising from the outside sources enumerated, enabling as it does their concentrating on the main essentials of their various contracts, and relieving them of the necessity of doing work which can be done in a plant near-

CANADIAN GOVERNMENT HOPPER BARGE NO. 2, BUILT AT COLLINGWOOD, ONT.

by, just as well, and oftentimes more promptly than they themselves could, through lack of reasonable opportunities; the cost besides is usually less. A "way-out" from munitions making may be said to be now offering to many of our smaller machine shops and foundries, by their seeking to supplement in the lesser details, the big undertakings of our shipbuilders, and if the same keenness to get the business, and expert application is directed to its subsequent handling, as were apparent in shell manufacture, there is little doubt but that equally satisfactory returns will follow.

It has been endeavored in the foregoing to present such data as meantime may dray attention to Canada's capacity and readiness to bear a part in the restoration of her Empire shipping status.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

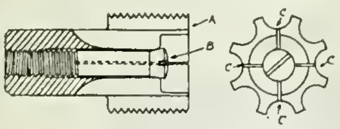
MAKING EXPANSION TAPS

By D. A. Baker

HAVING experienced considerable difficulty in tapping the base plug thread in the type 80 and 85 time fuse the tap described was designed and successfully used. Solid taps were difficult to make that would give us a thread which would gauge properly, and then difference in the metal, or wearing away of the tap gave very indifferent results and so an expansion tap seemed to be the only solution.

The sketch herewith shows the construction, A being the body of the tap, and B the expansion screw, while C, C, are four narrow slots milled into the body of the tap and carried back a short distance behind the threaded portion. The hole in the body of the tap for taking the expansion bolt was threaded for only about three-quarters of an inch from the back end, while the thread on the bolt was about twice as long. The clearance hole for the expansion bolt was made straight up to the front end, where it was slightly rounded over where the taper on the bolt came in contact with it. When grinding the face of the tap back of this part this corner should be kept rounded over with an oil stone so as not to bite into the taper.

In hardening this style of tap we found best results could be obtained by making up a soft steel nut which would



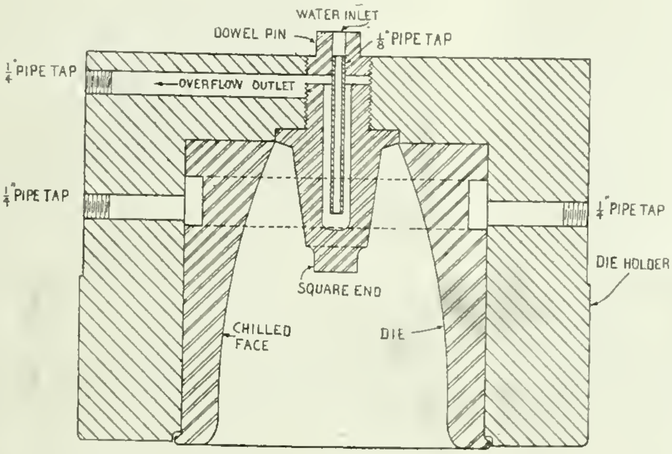
EXPANSION TAP.

just fit the tap, then dipping this and also the expansion screw into a mixture of graphite and oil, the nut, tap and the expansion screw were assembled, and in that condition put into the furnace. In this way the nut and the expansion screw held the tap from distorting, while the graphite and oil were to prevent the parts from sticking after having been through the fire. Taps were afterwards drawn to a blue except on cutting edges. These were drawn to a dark straw.

WATER-COOLED PIN FOR NOSING DIE

By H. P. Hoag.

IN the course of manufacturing 4.5 mark VII. shells, the writer found a continual source of trouble in the die pin which enters the nose of the shell and is subject to very severe wear, involving its renewal every day. The advantage of using water-cooling for the die was so marked that arrangements were made for water-cooling the pin also. The arrangement was as shown in the accompanying illustration. The dowel for centering the die-holder in press was drilled out, and a ⅛-in. pipe attached, which extended down into the



SHELL-NOSING DIE WITH WATER-COOLED PIN

pin, the hole in the pin being large enough to leave a space all around the ⅛-in. pipe. It will also be noticed that the threaded portion of the dowel is short enough to leave an opening between it and the die-pin.

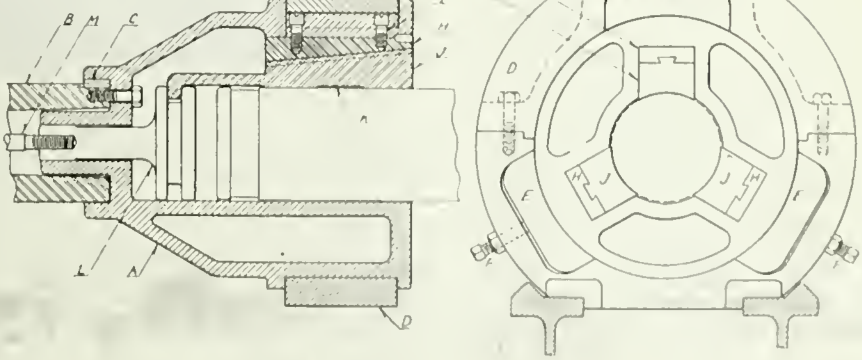
The action is as follows: Water is introduced down through a hole in the press to the hollow dowel into the die-pin, and is forced up along the inner wall and out over the end of the die-pin, thence through the side opening, as shown. The die is also shown with water-cooling arrangement. Die-pins cooled by such an arrangement as described have as long a life as the die itself, no matter how hard the press is worked.

SPECIAL HEAVY COLLET CHUCK

By R. Hamilton.

THE chucking of the larger shells, when performing operations on the interior, is one of the factors in the manufacture of munitions that has been given a great deal of thought and attention, and it is probably this feature, as much as any other, that has caused such radical departures in the design of special machines for the unit operation system. Before the advent of the self-contained chuck in the headstock of the lathe, it was necessary to attach a separate chucking device, together with a steady rest, in order to accomplish the desired purpose. The construction of these chucks is so varied that seldom will two plants be found with identical fixtures; the executives of each individual shop having developed their own particular design from past experience and existing available equipment. The general design of the spindle on the ordinary standard lathe does not permit of attaching these special chucks direct to the nose of the spindle; the practice being to secure the device to the face-plate of the lathe, or one that is specially provided for the purpose. The accompanying cut, however, shows one of these fixtures bolted direct to the spindle, and while in some respects it has a cumbersome appearance, it has proved highly satisfactory and efficient.

The main casing of the chuck is a



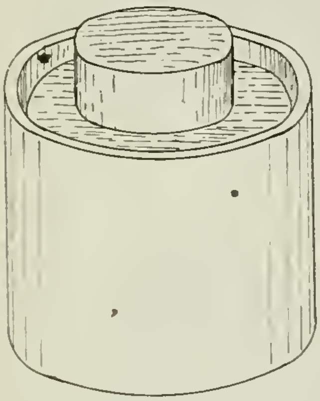
SPECIAL HEAVY COLLET CHUCK.

large casting cored out as shown in order to provide lightness with size. The casing A is secured direct to the nose of the spindle and locked in a permanent position by means of the key C, the outer end of the chuck body being supported by the steady rest D. This steady head is made in two halves, the lower section being fitted and secured to the ways of the lathe. Three slots are machined in the steady rest D, and fitted with the blocks E, these having a bearing surface of approximately 72 square inches each. The bearing blocks are adjustable by means of the screws F, the top block being fitted with retaining bolts G in order to prevent its falling out when the steady rest is free from the chuck. At three equi-distant points in the chuck casing, parallel slots, 4 inches wide, are machined to carry the operating mechanism. Secured to the bottom surface of each slot is the tapered block H, held in position by two fillister head screws I. The gripping jaws J are dovetailed to the blocks H, so that no springs are necessary to free the jaws from the shells after the pressure has been removed, the action being positive by the angle of the dove-tailed slide. With the exception of the relieved portion K, each jaw has a bearing 10 inches long and 4 inches wide on the surface of the shell. The outer end of the connecting piece L is a grooved collar that engages the tail of the three gripping jaws. The rod M connected the piece L with the operating cylinder placed at the outer end of the lathe spindle.

SAVING LEAD IN HARDENING BATH

By D. A. Hampson

A manufacturer of butcher and carving knives took a contract for hardening and tempering bayonets—for which he had an almost perfect equipment. His method was to heat them point down in tanks of molten lead. About that time the price of lead jumped and became a serious item, as each tank held a volume of it 30 in. in diameter by 22 in. deep. A scheme for reducing the volume of lead was evolved. It was to set a cylinder of cast iron about 18 in. dia. in the center of each tank displacing about 1400 lbs. of lead and it was quite successful. Once heated red hot it retained the heat very well, and hardening was just as efficient as before. Besides being a reducer of the volume of lead, it was a reducer of oxidation by leaving the smaller area of lead exposed to the air. In a few weeks the iron had paid for itself and was showing a profit.



LEAD SAVING DEVICE USED IN HARDENING BATH.

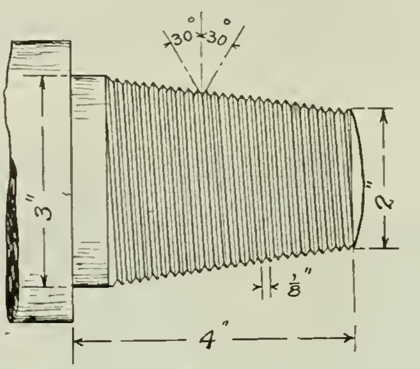
CUTTING WELL DRILL THREADS

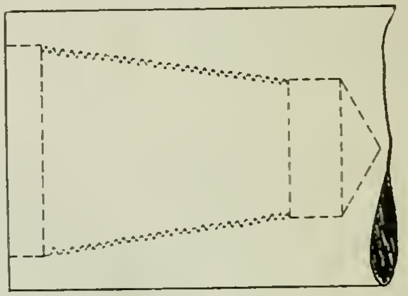
By D. A. Hampson

MACHINISTS who have never lived in the oil country or done artesian well work, have missed a branch of the business which is both rugged and interesting. The various well drillers' tools are bits, stems, jars, and drills, and are assembled in a "string" which is suspended at the end of a rope sometimes a quarter of a mile long, the "length" being depth down in the barrels of the earth. The tools are all forgings and are joined to each other by threaded joints of a decided taper. A typical joint is shown by the drawing which also shows the angle and pitch of the teeth. This is practically the accepted standard.

The form of end is not made so "a man will have to send back to the factory for repairs" but to facilitate field assembling, to prevent trouble with crossed threads, and mainly, to make it easier to screw two pieces together down in the bottom of a hole. Fishing out lost tools and screwing up joints a thousand feet out of sight is an everyday job to a well driller and the steep taper plays an important part. Tailstocks on ordinary lathes and taper attachments do not have enough set over for well threads and when they are cut outside of the maker's plant, it is a case of rig up for the job. The job of cutting some new male threads came into a shop that had nothing but the plainest of lathes to work with but by rigging up as shown in the photo, it was done very nicely.

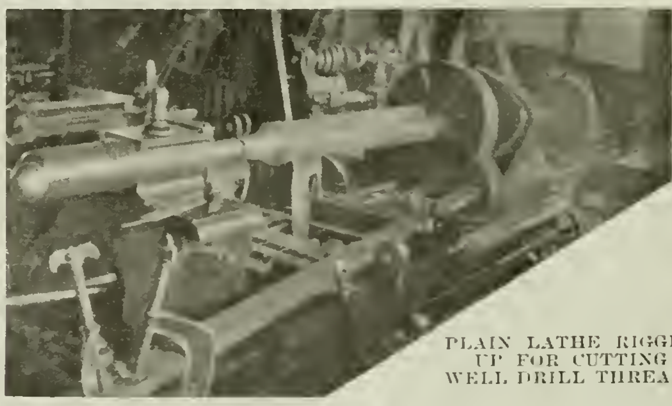
A bar of $1\frac{1}{4}$ in. x 3 in. cold drawn steel was clamped to two slotted parallels which were bolted across the ways of the lathe. This bar was set to the right taper and it was purposed to make the cross slide follow this taper as the carriage travelled. This was done by removing the cross feed screw and hanging a 50 lb. weight by a cord passing over the sheave wheel and attached to the cross slide member. The roller shown on the inside of the steel bar was set on an extension piece bolted to the side of the cross slide. This completed the taper arrangements. It may be added that they worked perfectly.





TYPE OF THREAD USED FOR COUPLING OIL WELL TOOLS.

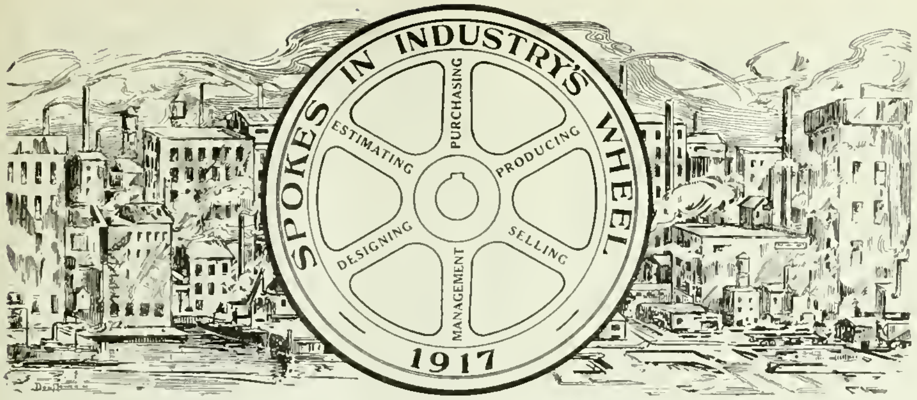
A reverse in the carriage was used for thread cutting just as with any threads but as the cross feed screw was removed and the lathe had no compound rest it was necessary to average for withdrawing the tool for every backing up of the carriage. This unit took the shape of a crude compound rest and was made up of parts on hand, the basis of which was a slide and its shoe, very well fitting, the end of one member showing in the photo by two upright ears through which a rod has passed on some previous job. In the solid metal just below these ears, a hole was drilled for a tool and a set screw for the latter put in.



PLAIN LATHE RIGGED UP FOR CUTTING WELL DRILL THREADS

Then an idle screw and a machine crank were added and the unit was complete ready to bolt in place of the ordinary tool post.

While a great deal of rigging up seems necessary for such a job, the special parts can be kept and used again at a profit. When a well driller has a break down, he usually has three or four men at good wages whose time goes on, work or not, and he is willing to pay any price in reason—and a little more—to be helped out.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

HERBERT WILLIAM CARTER

A STUDY of industrial developments in Canada during the past decade reveals a series of fortunate happenings combining the elements of time place and man. In most branches of industry it will be found that the last ten years have witnessed several developments in machines, methods and processes, the lack of any of which at this time would be a national handicap, and the future possession of which will not be without considerable influence, even though indirectly, on the development of the country. Present efforts in the field of industrial research will yield results in time, but it may be questioned whether the future holds secrets of such particular importance to the engineering industry as say high speed steel, non-ferrous alloys and autogenous welding. The gradual and persistent manner in which the last of these, better known as the oxy-acetylene process, has permeated the entire industrial world is at once an evidence of its inherent merit and a tribute to the pioneers of the process. Future manufacturing developments in this country are bound to witness an increasing use of the process and considerable interest, therefore, attaches to the personality of our "Spoke" in this issue.

"Opportunities are made to be taken" and the success which has attended the business activities of Herbert William Carter, president of the Carter Welding Co., Ltd., Toronto, is evidence that he grasped the occasion as well as truth of the saying. While our Spoke's residence in Canada covers a period of about nine years, the fact that he has devoted all of this time to the development of oxy-acetylene welding accounts for him being regarded as much in the light of being an institution as well as a pioneer. This concentration of purpose is easily understood, however, when Mr. Carter's earlier experience is considered.

Born in Bristol, England, of English parents, Nov. 11, 1889, H. W. Carter passed through the curriculum of the usual English high school education, and in 1904 began work as an apprentice in shops of the Rope Walk Iron Works, Bristol, of which his father was proprietor. Forgings for motor car parts were the principal output of the business, and ample opportunity was available for acquiring skill and knowledge in the handling of forge work, an experience which was to be of exceeding value in his chosen vocation here. Handicraft skill like other accomplishments is frequently hereditary, and the fact that Mr. Carter's father enjoyed a wide reputation as a forging expert in the land of his birth, may, to some considerable extent account for the success which has attended our "Spoke's" efforts in this country.

HERBERT WILLIAM CARTER.

An extended experience in general garage work, and close intimacy with the leading motor car builders of England, during their most active period of development, still further fitted our friend for appreciating the possibilities of autogenous welding. Soon after his arrival in this country in 1908, Mr. Carter assumed the representation of Davis-Bournonville Co., whose apparatus had attained a high degree of commercial efficiency, and the steady growth of the process in this country is to a large extent due to the faith of Mr. Carter in the possibilities of the process, the efficiency of the equipment he handles, and his own ability to accomplish what he sets out to do.

Prominent among his personal efforts was the developing of the use of oxygen for removing carbon from internal combustion engine cylinders, a line of effort resulting directly from his early days in the motor car business. More recent, but none the less important was development of an oxygen gas cutting-off machine which has already found considerable application in munitions manufacture, while the rapid extension of aeroplane building in this country has offered further opportunity for application of his inventive faculty.

Processes such as Mr. Carter is concerned with, become so closely interwoven with their numerous fields of application that their novelty is soon lost and only their merit remains; it will be of interest, however, to those of our readers who have used a "torch," to know that the man who made the first weld by oxy-acetylene in Canada is employed by Mr. Carter.

Despite the activity of his life in Canada, our friend has found time to maintain the English traditions of home and family; in 1912 he entered the bonds of matrimony. Mrs. Carter is also of English nationality, and is the mother of two sons, the family residence being at 944 Dufferin St., Toronto.

Mr. Carter's affiliation activities are limited to the A. O. of Buffalo of which he had the honor of being the youngest member at the time of his initiation; in religion he is Church of England.

Frequent opportunities for continental travel were fully availed of during his residence in Britain, and coast to coast trips in Canada and across the line have marked his stay here. Motoring is the principal recreation of our friend, although the investigation of oxy-acetylene applications and allied scientific work is prosecuted in a manner which combines work and play to a great extent.

As the pioneer of an industry, Mr. Carter has been deeply impressed with the value of technical journals as a means of collecting information, finding and developing prospects, and keeping in touch with the trade generally: "A new business, more than any other, must seek means for disseminating information amongst selected parties, and the technical paper of to-day not only does this very effectively, but does it continuously. Not only do the advertising features keep the various sections of the trades in constant touch with each other, but the editorial features assist in maintaining executives and employees in a state of greater efficiency. Young men entering new branches of business at this time can not afford to neglect any of the suggestions and inspirations which arise from the careful perusal of technical journals.

MOVING PICTURES OF MUNITIONS MAKING

THE John Bertram & Sons Co., of Dundas, Ont., who recently completed a large contract for 8-inch high explosive shell, arranged to have made a moving picture record of the operations. The work was undertaken under the direction of W. T. Sears, secretary of the Engineering Committee of the Niles-Bement-Pond Co., the pictures themselves being photographed by F. T. Van Syckel, staff photographer for the latter concern, who moved from one end of the shop to the other, aboard an overhead travelling crane.

The films take up the manufacture of eight-inch high explosive shell from the time the rough forging is received. A general view of the shell plant is first shown. Details of the various operations are clearly shown; the views being taken close up are unusually clear and distinct. The film, which is in five parts, traces the entire series of operations right through until the finished shell is boxed ready for shipment. An interesting feature was the statement preceding each operation, giving the time required; another was the Government inspection, which demonstrated the many gauges used.

A pleasing introduction to the film was the appearance of the photograph of the founder of the business, John Bertram, and the present head, Henry Bertram. A group picture showing the foremen, and another showing the Government inspectors were included. It is understood that the pictures were taken entirely as a matter af record, and will be carefully preserved by the John Bertram & Sons Co. A representative of this publication was fortunate to see them exhibited in the interest of funds for the Patriotic Society of the town of Dundas, where the Bertram plant is located.

GOVERNMENT CONTROL FOR ALL BRITISH INDUSTRIES

LATEST advices from London state that the Government has introduced a bill which is almost certain to pass quickly, which provides for State domination of practically all industries. The munition acts, already effective, enumerate many industries which the Minister of Munitions may take over and operate for the Government. The new bill proposes to give the Minister of Munitions power to do this with any industry if it is deemed necessary, thus making the whole industry of the nation a war works.

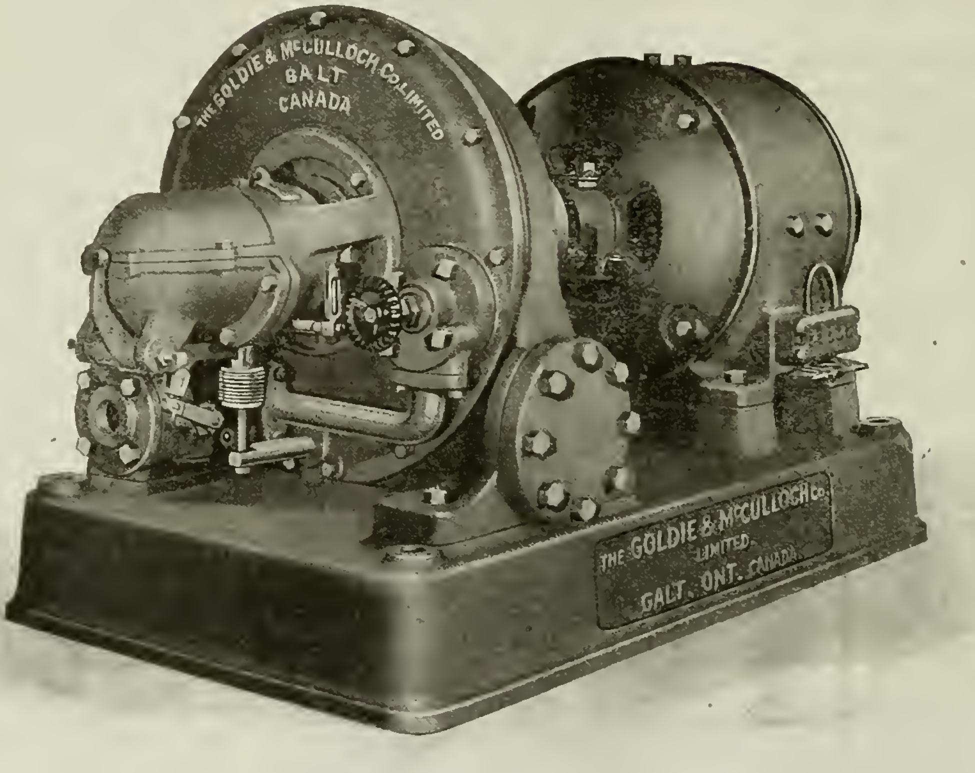
The bill provides that in case the Government takes over a given industry many. During the past year at least one governing output and conditions of workmen and the like, then limitations on profits also will be imposed.

DEMONSTRATION OF METAL SPRAYING PROCESS.

CONSIDERABLE interest was manifested by manufacturers in Toronto and Western Ontario in a recent demonstration of the Schoop Process of Metal Spraying by the Metals Coating Co., of Canada, Ltd., at the plant of the Dominion Bridge Co., Toronto. Although, a comparatively recent accomplishment, the Schoop process, which takes its name from one of its prominent sponsors, a Swiss engineer, has been for several years in successful operation in many European countries, and is now being adopted by progressive Canadian and American manufacturers.

In the Schoop process, the coating adheres to the object chiefly by mechanical union. The apparatus is so designed that either hydrogen, Blau, or acetylene gas are used in conjunction with oxygen, the reducing gas being always in excess so that oxidization of the metals is prevented. Compressed air discharges the products of combustion at a high velocity so that the molecular spray by penetration secures a perfect adherence to the surface being coated, and rapidly builds up to the depth required.

All kinds of protective metals and their alloys can be utilized and applied to metals, wood, paper, stone, clay, cement, cotton and silk fabrics, and glass.



TURBINE-DRIVEN SHIP LIGHTING SET.

NEW ZEALAND TRADE FOR CANADA

A REPORT received by the Department of Trade and Commerce, Ottawa, from Canadian Trade Commissioner Beddoe, of Auckland, says that a Canadian firm recently sent out to New Zealand samples of lead pencils, the first made in Canada following the stopping of the Austrian supply. Mr. Beddoe says that the samples were found very satisfactory, and substantial orders have been sent to Canada. He also notes that if Canadian firms were not so busy with war orders they could capture in New Zealand a much greater proportion of the business formerly enjoyed by Germany. During the past year at least one million dollars' worth of New Zealand orders offered to Canadian firms could not be filled.

MACHINISTS' INSTRUCTION COURSE—XVII.

By J. Davies.

IF the size or shape of the work prevent it being held in the vise, it may be bolted to the table by means of the bolts and plates already described. Work on the planer or shaper is usually

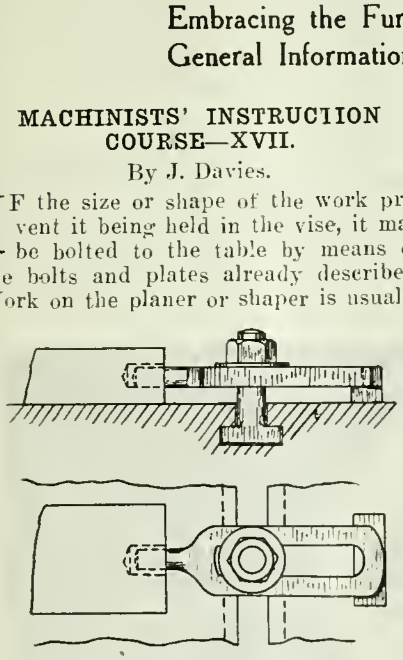

FIG. 61.

set up by means of the surface gauge; although this is not by any means an infallible test, it is usually accurate enough for ordinary work. A more accurate way is to test by the tool itself, after setting up the work, as the shaper table is not always in line with the travel of the tool, neither is the bridge or cross rail of the planer always parallel with the table.

Bolting Down the Work

Few machinists realize how easily a casting, even of very large size, can be sprung by careless bolting down to the table. Before finishing a casting on the planer that needs to be machined very accurately, it should be roughed all over, as in some castings, depending largely upon their shape, there is a certain amount of internal stress due to unequal cooling in the mould, and they are liable to spring a little when the outer surface has been removed. If a piece of work is to be planed parallel top and bottom, af-

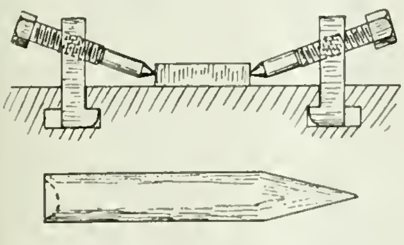

FIG. 62.

ter being set up in the required position, any uneven places at the bottom should be packed up so as to give a good solid bearing surface before being finally bolted down; otherwise the work will be sprung by the bolting down, and when the bolts are released it will go back nearly to its original shape, with the result that the planed surface will not be true.

Sometimes a piece of flat work is to be finished on both sides, and it is found that there is no place to put the clamps except on the top surface, so that some other means must be found to hold down the work. If the work is thick enough and holes are no detriment, these may be drilled in the sides or edges of the work, and the work bolted down by using finger clamps, Fig. 61.

When it is undesirable to drill holes in the work, toe clamps are usually resorted to. This equipment consists of pieces of wrought iron or steel made to fit the slots of the table, with a hole drilled and tapped at a slight angle to receive a set screw. Pieces of steel of a suitable length are ground, one end with a ball point to fit the cupped end of the set screws, the other with either a chisel or centre punch end to press against the work (see Fig. 62). Care must be taken that the angle of the toe dog is not too great—the angle of the tapped hole is usually 8 or 10 deg., just enough to insure that the dog will press the work hard down to the table. When using toe dogs, stop pins must be used to prevent the work slipping on the table. When

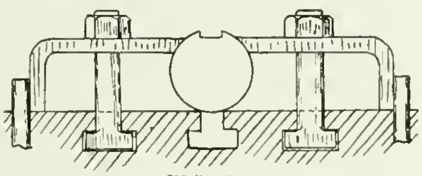

FIG. 63.

using chisel-pointed toe-dogs, cup out the ends and use pointed set screws.

If a long, round shaft is to have a keyway or spline, cut from end to end, it may be bolted to the table in a somewhat similar manner by placing the shaft in one of the longitudinal slots and bolting at the sides with plates, as shown in Fig. 63.

For short, round shafts it may be convenient to support the end on V-blocks and grip the centre by the vise.

Planing Curves

Many are the ingenious devices used on the planer for special work. Mention is made of one or two of those most likely to be met with in ordinary machine shop work. The first is a device used for planing a curved surface on a casting.

Fig. 64 shows one form of a special rig for planing curved surfaces. A special head or an extension to the ordinary head is made to swing on a pin on the upper cross brace, the distance from the centre of the pin to the point of the tool being the same as the radius of the desired curve. It may be necessary to remove the ordinary feed screw to allow for the swing of the tool, and some temporary device made to feed the tool across the work. These devices may vary somewhat, according to the construction of the machine, but the prin-

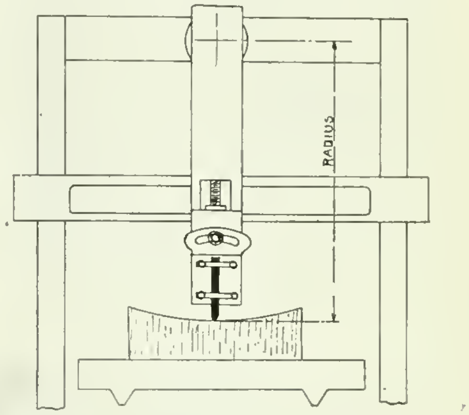

FIG. 64.

ciple of planing curved surfaces is the same.

Planing Links

In planing links, such as are used for locomotives, etc., the tool is stationary except for the downward feed, and the work is made to travel through a curved path. This is accomplished in several ways. The most satisfactory is where the work is bolted to an extra table held between strips, which hold it from moving lengthwise on the table, but allow it to travel transversely across the table (see Fig. 65. Attached to this extra table is a bar with a hole in it the required radius. Through this hole passes a pivot pin, which is fastened to some secure support. If it is a very large radius, which requires but a very slight cross motion of the extra table and necessarily a very long arm, the support for this pivot pin would probably be on a special

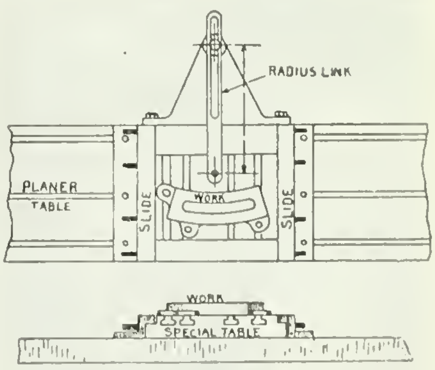

FIG. 65

concrete foundation of its own. If the radius is a very small one and the pivot pin must be close up to the planer table, it can be very conveniently supported by a bracket bolted to the side of the planer. As the table moves backwards and forwards the extra plate to which the work is fastened rotates about the centre of the pivot pin, and in so doing slides backwards and forwards across the table. Where frequent variations in radius occur, the link may be slotted and the pivot pin adjusted to different radii, as shown in sketch.

Work Between Centres

A pair of centres is a very useful attachment for some planer work, such as planing the corrugations in long rolls used in making corrugated paper. In work of this kind it is advisable to fasten a gear on to the shaft to be used as an index for planing the right number of teeth or corrugations. The spacing is done by making a spring finger to fit the teeth and fasten to the table (Fig. 66).

Spirals can be cut in much the same way. In cutting spirals, a clamp is fastened to the work with the end extending across the table. The end of this clamp

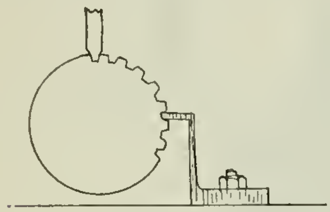

FIG. 66.

travels up and down an inclined plane that is fastened to the housing of the planer, and is kept in contact with it by a suitable weight. As the table travels backwards and forwards, on account of the inclined position of the piece bolted to the housing, it forces the work to make a partial revolution with each stroke of the planer. By varying the angle of this bar, the amount of travel on the work can be regulated. The steeper the angle formed, the steeper will be the pitch of the spiral. The planing is done with a tool formed to the desired shape. The right number of spirals can be obtained by a ratchet wheel arrangement, which can be made to move any number of teeth each stroke of the table.

GROUP OF CYLINDERS RECLAIMED BY OXY-ACETYLENE WELDING

BOILING PATCHING WITH OXY-ACETYLENE.

By S. W.

THE accompanying photograph shows a method which has recently been adopted for applying patches to boilers, whether inside the firebox or outside the shell. The old method was to fit the patch over the weak plate, making a lap joint all around, which was finally riveted into position, after which staybolt holes were drilled,applied and riveted. Much blacksmith work is necessitated in the fitting. The new method consists of cutting out the weak place with the oxy-acetylene cutting torch, then cutting a piece of plate to fit hole, after which staybolt holes are drilled and applied, thus holding the patch in position as shown in photograph. A vee groove is now chipped around the joint and the crack welded up solid to main plate with oxy-acetylene welding torch. Cost of new method less than half that of old.

PATCH ON LOCOMOTIVE FIRE-BOX HELD IN PLACE BY NEW STAY BOLTS PREPARATORY TO WELDING UP EDGES.

RECLAIMING SCRAP CYLINDERS

By E. T. S.

OWING to changes in the design of our equipment, a large number of long air reservoirs were put out of service. These were carefully stored in the museum, and when an opportunity occurred in which it was possible to use up this stock, were cut to the length required, by the oxy-acetylene process, and the old end was welded in by the same process in the new position. The cost of these tanks new would have been \$7.80 each, and the cost of cutting the old tanks down was \$3.37 each, making a saving of \$4.43 each, accomplished entirely by a system of "checking the scrap."

KEROSENE AS A GAS ENGINE FUEL

By L. G. Heimpel, O.A.C.

THERE are hundreds of gasoline engines in use on Ontario farms at the present time, which are not the cheap source of power that they once were, and still should be, because of the recent rise in price of gasoline. A gasoline engine in good working order, and with gasoline at fifteen to twenty cents a gallon, is as satisfactory and as cheap a form of power as any other within the reach of the average farm.

Some years ago, gasoline was considered fairly good in quality when it tested 70-72 (Baume scale). At the present time it tests all the way from 59 to 66, which means that the speed with which it evaporates has decreased by the difference between these figures. In other words, volatility, which is the quality which makes it valuable as an internal combustion engine fuel, has deteriorated by that amount. The hydrometer (Baume scale), gives the test of average kerosene (coal oil), as from 42 to 46, which shows us that the difference between the volatility of coal oil and that of gasoline is growing less. In spite of the fact that the quality of gasoline is deteriorating we find the price rising—almost doubling that of a few years ago—and it behooves us to find some way of using a cheaper fuel for our gasoline engines.

Kerosene As a Substitute

For this purpose we have found kerosene, as well as naptha and fuel oil, to be quite satisfactory. Furthermore, it is an easy matter, as well as one that involves little expense, for any man who has taken the trouble to find out why and how his engine runs, to convert his engine, which was made to burn gasoline, into a kerosene burning engine.

The Relation of Kerosene and Gasoline

Before going on to describe the essentials of a coal oil burning device, we shall endeavor to show what gasoline and kerosene are, and how closely these products of the oil refinery are related. Both are products of petroleum. The crude petroleum is distilled in large iron stills and purified. The mass of oil is heated from 120 degs. C. to 150 degs. C. and held at, or near, the highest point mentioned, and all the vapor that passes off at that temperature is called gasoline. When no more vapor passes off, the temperature of the mass is raised from 150 degs. C. to 300 degs. C., and all vapor passing off at that temperature is condensed in a separate tank and forms such products as kerosene, naptha and fuel oils. Kerosene is therefore composed of the same constituents as gaso-

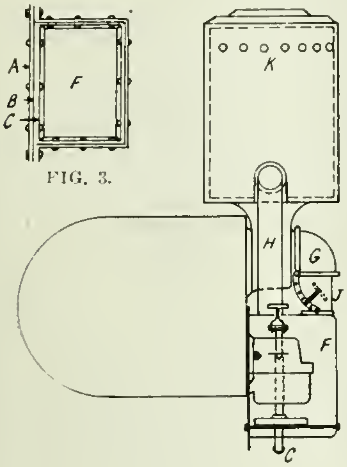

FIG. 3.

FIG. 1.

line, but it will not evaporate as readily as the latter, and it contains a larger percentage of carbon. Kerosene really contains more heat units per gallon than gasoline, but the problem before us is—how to get them out?

The conditions essential to the burning of kerosene are:—

1. Kerosene must be heated to its evaporating point outside of the cylinder and held at that point until it is ignited by the electric spark in the explosion chamber.

2. The air which is drawn in through the carbureter must be heated.

3. Water must be fed into the cylinder at the same time.

Heating the Oil

It is first of all necessary to state that up to the present we have discovered no satisfactory method of starting our engines on anything but gasoline, and hence appliances for this purpose must be provided. There are two kinds of fuel feeds in use at the present time—first, the gravity feed, in which the fuel tank is above the carbureter and the feed regulated by a float or diaphragm, and second, the constant level feed, in which we have the fuel level kept uniform by pumping a surplus of fuel into it; the excess running back to the tank through the overflow pipe.

The devices employed for heating the fuel in a gravity-feed engine are illustrated in Figs 1 and, 2 Fig. 1 representing an end view of a cylinder, carbureter and muffler of a gasoline engine, while Fig. 2 is a side view of the same. The dotted lines show the carbureter and heating tank D as they are enclosed in the box F.

On its way from the tank to the cylinder the oil passes through pipe A in the stand-pipe B, which is also a sediment and water trap, then through pipe C into heating tank D, from which it is drawn into the expansion chamber through the needle valve E. The heating tank should be either a thin rectangular tank holding from one-half to three-fourths of a pint of fuel, depending on the size of the engine, or it may consist of a coil of perhaps six or eight feet of ½ in. flexible copper tubing in which the oil is heated. In order to keep the fuel hot enough it is necessary to heat the carbureter as well as the oil; this is done by enclosing the carbureter in the sheet iron box F and piping about 40 or 50 per cent. of the exhaust of the engine into it, allowing it to escape through a hole in the opposite corner of the box. This is done by cutting a hole into the exhaust manifold and leading the exhaust through pipe G into the heating box. In Fig. 1, J shows a home-made butterfly valve by which the amount of heat entering the heating box can be diminished or increased at will. The construction of the heating box F is explained in Fig. 3, and with a little modification a similar device can be made to fit almost any engine. In Fig. 3, A is a stiff sheet iron plate which is held in place by being clamped in with the gasket on the studs which hold the carbureter. The top, bottom and one side of this box are one piece of metal bent to shape. The ends are of the same material and are fastened to the sides by bending the edges to form a flange, then bolting the sides and edges together with stove bolts. The joints can be made as tight as necessary by inserting a layer of asbestos paper.

Starting an Engine

The operation of starting an engine equipped in this manner is as follows:—

1. Close stop cock M so as to prevent kerosene from running into the carbureter.

2. Drain the kerosene out of the car-

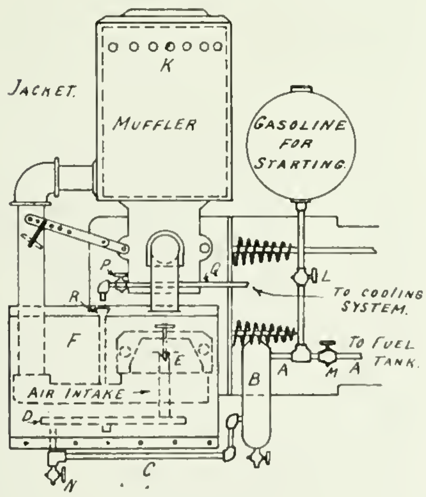

FIG. 2.

bureter and heating tank through stopcock N, after which close N.

3. Open stop-cock L to allow gasoline to run into carbureter and start the engine as usual. When it is hot, all that is necessary to change to kerosene is to close stop-cock L and opening M, so as to allow the kerosene free passage to the carbureter.

The principle for heating the fuel in an engine with a pump and constant level fuel feed remains the same, but since a far larger amount of fuel is being pumped through the system than the engine requires, it follows that the tank heater is not efficient. Therefore, we must resort to such a device as is

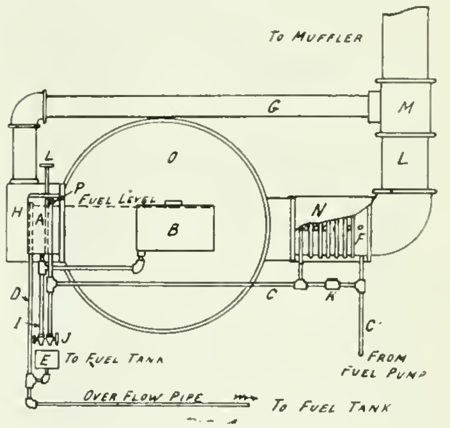

FIG. 4.

shown in Fig. 4. In this figure, O is the end of the cylinder of the engine; F is a coil of about 15 feet of quarter-inch pipe coiled around the exhaust pipe into which a series of holes have been drilled for the escape of hot gases; N is a sheet iron cover which encloses the coil of pipe.

The fuel is pumped through the pipe C, Fig. 4, into the carbureter at P, and the excess returns to the tank through overflow-pipe D. When kerosene is used the valve K is closed and the oil is forced through the coil F where it is heated. When gasoline is used as fuel, opening of the valve K will allow the passage of the gasoline without heating it.

The heating of the carbureter is brought about in a manner similar to that in Figs. 1 and 2.

In starting an engine equipped as in Fig. 4, the following points are necessary:—

1. Drain kerosene out of carbureter through pet-cock on pipe I.

2. Fill tank B with gasoline. This tank should be large enough to hold for 20 minutes running. It is placed so that its top is level with the top of the carbureter and its bottom level with the bottom of the carbureter.

3. The pet-cock J is opened so as to allow the escape of all kerosene which is pumped through the pipe C, back to the tank.

4. Start the engine and when gasoline is run out turn on the kerosene by closing pet-cock J.

Heating the Air

It is necessary to heat the air so as to prevent condensation of the vaporized fuel particles into the liquid by the inrush of cold air into the air tanks. This is very important, and if the passage between the carbureter and the cylinder is a long one, and in a multicylinder engine it must be jacketed and heated with exhaust or the fuel mixture will condense on its way to the explosion chamber.

The best way to heat the air is to force the intake air to be drawn over the hot surface of the muffler or exhaust pipe. In Fig. 2 is shown a muffler with a jacket of sheet iron. The space between the jacket and the muffler should be no more than half an inch. All the air is drawn in through the holes K at the top of the muffler and is conducted through the pipe H to the carbureter.

The Feeding of Water

Water is fed into the carbureter of a kerosene burning engine for two purposes, to prevent "knocking" and to prevent carbon deposits in the cylinder and consequent fouling of the ignition apparatus. Modern kerosene burning engines are fitted with a water carburter of similar design as the fuel carbureter, but when remodelling an engine not fitted for kerosene we find that a device such as is illustrated in Fig. 2 answers the purpose very well. Water taken from the cooling system of the engine passes through pipe Q and drops into the funnel R, thence into the air intake. The amount of water fed can be regulated by pet-cock P.

During the summer of 1916 we used a device as just described on the twenty horse-power engine driving the traction ditching machine used as a demonstrator by the Department of Physics of the Ontario Agricultural College. The writer made a number of actual working tests for the purpose of ascertaining the efficiency of kerosene and other cheap fuel oils as compared with that of gasoline. In each test we found that the gallon of kerosene did as much work as a gallon of gasoline. This means that with kerosene at from 12 to 13 cents a gallon and gasoline at from 33 to 35 cents, our fuel bill was cut to less than half of what it would have been had we been burning gasoline. Gasoline is high in price; the demand is growing; and the supply is limited; therefore we cannot see that it is likely to become any cheaper. For these reasons we hold that gas engine owners cannot do better than to equip their engines so as to burn kerosene.

TESTS OF URANIUM AND OTHER HIGH SPEED STEELS

THE difficulty of obtaining reliable comparisons of high speed steels under ordinary shop conditions are known to all students of the subject, and recent efforts by the Standard Alloys Co., Pittsburgh, to obtain accurate figures were somewhat nullified due to the presence of hard spots, extra high carbon, and similar inequalities which made it impossible to figure one steel in terms of the other.

Four bars of high speed steel each having different chemical composition, were tested with a view to determining their relative physical fitness for lathe tools. The work they were tested on consisted of turning forged pinion blanks from 5 to 6 in. dia. the material being very uniform both chemically and physically, so that a good comparison between the tools was obtained. The pinions were turned at an average speed of 54 ft. per min. with 1-32 in. feed and 5-32 in. depth of cut. The alloy in uranium tool No. 1, was charged with the metal, and in No. 3 was charged after the steel had melted. This difference in charging caused No. 1 tool to have less uranium than No. 3. In uranium tool No. 966, the elements were in very good proportions to give hardness and strength. Tool A was a high speed steel of recognized quality taken from the ordinary stock in the shop.

COMPARATIVE WORK DONE BY HIGH SPEED STEELS.

Tool	Av. No. Pinions Faced	Dia.	Face	Distance along Axis	Area Turned sq. ft.
Uran. 1	50	5.6"	4.81"	21.38'	27.14
" 3	53	5.45"	5"	21.9'	32.52
" 966	58	5.68"	5.2"	24.0'	33.78
A	45	5.75"	5"	18.6'	28.05

The results obtained as shown in the accompanying table are obtained by averaging up from three to four grindings, so as to get a more accurate test than when single grindings only are considered. The number of pinions turned is mentioned to give an idea of the amount of work turned.

It will be noticed the tool A showed up slightly better than tool No. 1, while both tool No. 3 and tool No. 966 are about even in their cutting ability, and both surpass tool A.

SAFETY IN THE MACHINE SHOP—THE AUTOMATIC MACHINE DEPARTMENT

Travelers Standard

THE most successful manufacturers of to-day are giving a great deal of study to the methods employed in their plants, with a view to increased efficiency. Keen competition has forced out of business many of those who were unwilling or financially unable to adopt the most approved methods and practices, and to install labor-saving and time-saving machines and devices.

The improvements in metal-working machines have been particularly noteworthy. A comparatively few years ago, with the tools then in use, the services of a skilled machinist were required to perform even the simpler operations in metal working. Especially was this true when a number of duplicate parts were required, the value of which would be impaired by the slightest variation in size or style. Men who could turn out satisfactory work of this kind were in great demand and consequently were well paid. Now, after a few days' training, an unskilled workman may be put in charge of one or more automatic machines which will produce thousands of small objects per day, which will be absolutely uniform in size and style.

Automatic Machine Features

The modern automatic screw machine, as used at the present time in practically all manufacturing machine shops, is by no means limited to the production of screws. It turns out bolts, nuts, and gear blanks, and various parts of locks, fuses, spark plugs, guns, typewriters, and automobiles, as well as other objects in great variety. The automatic screw machine is the result of a process of evolution. The first screws made were cut by hand with crude implements, and this laborious hand-method was followed for a great many years. In 1775, however, the first metal-working lathe was constructed and used in England, and for a long time thereafter it was employed for manufacturing screws, bolts, and nuts, and duplicate parts of various kinds, although it was extremely inefficient for this particular kind of work, from a modern point of view. With this machine, the production of small duplicate parts was limited, because a great deal of time was consumed in placing and securing the stock in changing the tools, which necessitated frequent starting and stopping of the lathe.

These objections were overcome and better results were obtained, as regards quantity and uniformity of production, by the hand screw machine which was subsequently developed. With this device, the tools could be set in position and swung to the work by the operator without stopping the machine, and consequently a considerable saving of labor and time was effected. The automatic screw machine soon followed, and this performs the operations of feeding the stock, chucking, and bringing the tool to position automatically, by mechanical means. All that is required of the operator is to make sure that the tools are sharp, to keep the automatic mechanism in proper adjustment, and to supply stock. The multiple-spindle automatic machine is the latest development in equipment of this kir

Accident Possibilities

Accidents occur in connection with automatic machines, as well as with machines of every other kind; and although the injuries are usually of a minor nature, some of them are quite serious, and occasionally a fatality occurs. Hence it is well worth while to consider what can be done to increase the safety of the employees, and a few of the points that should receive attention are mentioned in the following paragraphs.

Storage and Transportation of Stock

In a good-sized machine shop there may be two hundred or more automatic machines, which may turn into finished products perhaps forty tons of bar stock per day. The bars that are used are often as large as 3½ inches in diameter and 12 feet or more in length, and a great number must be kept in stock in order to avoid delays and shut-downs. It is, therefore, important to have a suitable place for storing them, and to see that they are piled in a safe manner, so that they cannot roll and injure the hands or feet of the workmen. The bars should be assorted according to size, and should be kept in strong, substantial racks so that any required size may be had without delay or inconvenience.

The work of unloading the bars from the railroad cars and transporting them to the stock room is also of a more or less dangerous character. The bars should be unloaded in such a way that none of them will overhang, or be left in such positions that they may roll or slide; and they should preferably be kept in a horizontal position while being unloaded. If conveyors are used, precautions should be taken to prevent the bars from rolling off them, or from interfering with the conveying mechanism in any way, or from injuring persons who may be near. Hand hoists are frequently employed, and then it is essential to see that the slings and all parts of the hoisting apparatus are kept in safe condition.

Machine Guards

It is highly important to provide adequate guards for all the exposed gears, clutches, driving belts, and pulleys on the automatic machines, because the floors around these machines are made quite slippery by the cutting oil that is constantly thrown from the tools as the stream of oil strikes them. Many injuries are due to persons slipping and coming in contact with unprotected gears and belts. It is advisable to place sheet metal screens about the machines to intercept the oil, but even when this precaution is taken more or less oil will be spattered about. It should not be allowed to accumulate in any considerable quantity, however, but should be cleaned up promptly and systematically. Sometimes the floor about the machines is covered with tin or sheet metal, but we do not approve of this because it tends to make the floors more slippery. Oily floors should be washed daily with hot water containing strong alkaline soap. When sawdust is sprinkled upon the floors, it should not be left long enough to become thoroughly saturated with oil, but should be changed frequently. To reduce the likelihood of slipping, the soles and heels of the shoes worn by the employees should be made of leather instead of rubber.

So far as possible, bars of stock should be of such a length that they will not project beyond the ends of the extension guards of the machines. Otherwise, loose clothing may be caught and wound up on the revolving bars; or, if they are of small size, the bars may wobble about and strike persons who may be near. Substantial racks should be attached to the machines, or be located near them, upon which a temporary supply of bars may be kept. This is much safer than laying them upon the floor, where they are likely to roll about and cause persons to fall or stumble.

Shafting, Belt, and Pulleys Guards

The shafting, belts, and pulleys, underneath the slotting and threading machines, should be effectively guarded so that the clothing of the employees (particularly the skirts of women operators) will not become caught. The women should keep their hair closely confined by means of caps or nets, so that it may not be caught in moving machinery, and none of the operators should be allowed to wear loose-fitting, torn, or ragged garments. The automatic slotting and shaving machine is quite ingenious. The screws are fed to it through a hopper, and the heads are slotted and shaved automatically. The chief danger, here, is that the employees may come in contact with the rapidly-revolving saw, or have their clothing caught in the shafting. Suitable guards should be installed, therefore, to avert accidents of this kind so far as possible.

Heading machines are frequently used for the production of various special kinds of nails and screws. These machines use a wire stock, which is fed automatically from a coil. The head is formed by "upsetting" the end of the wire by a heavy blow, and at the same time the piece is cut off to the correct length. The pulleys and driving belts on a machine of this kind should be effectively guarded. This is of special importance, because the machines are often set quite closely together. As a rule, the noise in this department is almost deafening, and it should be reduced as much as practicable. This may be accomplished, in part at least, by interposing felt or some other equally effective insulating material between the floor and the machines. In this way the shocks and noise may be materially deadened, and the vibrations checked. After coming from the heading machines the blanks are placed in tumbling barrels to be cleaned, and frequently the threads are formed by thread-rolling machines. The pulleys, driving belts, and balance wheels on the thread-rolling machines should be efficiently guarded, particularly when the space between the machines is insufficient to insure the safe passage of the employees.

Condition of Tools

The tools for automatic machines must be kept in good cutting condition, and consequently they must be frequently ground on emery wheels. Eye-protectors should be worn by the men who do the grinding, because many injuries are caused by particles of steel or emery lodging in the eyes. The dressing of the grinding wheels must also be done with the utmost caution, if accidents are to be avoided.

Oil Removal From Chips

The method used for treating the metal chips and scraps, in order to save the large amounts of cutting oil with which they are covered, is worthy of consideration. The chips are shoveled into baskets, which are then placed in a centrifugal extractor which removes the oil from the chips by centrifugal force when the machine is set in motion. The extractors are operated at high speed, and, therefore, the covers holding the baskets should be securely fastened before starting the machines. There should be frequent inspections to make sure that none of the threads of the holding bolts or nuts have been stripped.

Serious accidents have been known to occur when these covers have become loosened and have been thrown off. The screws or bolts holding the base of the machine to the floor should also be periodically examined, because the excessive vibration may cause them to work loose; and if the floor is of wood the deteriorating effect of the soda water that is spilled from the cleaning troughs or tanks may also cause the bolts to loosen. The driving belt of the extractor should be guarded to a height of 6 feet above the floor, with a guard of sufficient strength to withstand any blow that might be given by the belt if it should break while moving at high speed.

The soda water tanks are usually low iron troughs in which the products of the various machines are immersed to remove any oil that may be upon them. The floors about these tanks or troughs are often in poor condition, and slippery; and the workmen engaged in the vicinity must be careful to avoid slipping or stumbling and falling into the tanks, where they may be severely scalded. Burns and scalds may also be caused by the careless dumping of screw machine products into the troughs, resulting in a considerable amount of unnecessary spattering of hot water.

Cuts and scratches on the hands are quite common in machine shops. These wounds should be immediately washed out with an antiseptic solution, and be carefully bound up to prevent infection. This precaution is important even in the case of very slight injuries, because serious cases of blood poisoning often result from small wounds that have not received proper care.

Infections From Cutting Oils

Considerable trouble is experienced in some shops from infections caused by certain kinds of cutting oil—notably the cheaper grades of lard oil. Cutting oils may be made from almost any kind of animal matter, and frequently no precautions are taken by the manufacturers to sterilize them. Moreover, even if the oil is free from germs when first used, it is likely to become infected later; and as the machine operators' hands are usually covered with the oil, any slight wounds or abrasions of the skin may allow the bacteria to enter the blood. To prevent trouble of this kind, it is advisable to sterilize the cutting oil before using it, and also at frequent intervals thereafter. The experiment is also being tried of mixing the cutting oil with a germicide of some kind (such as carbolic acid or cresol); but we do not yet know how effective this plan will prove to be.

Some plants simply use a sal-soda solution, in place of cutting oil, for working soft metal, and paraffin oil or some other kind of mineral oil for other operations. With these there is little danger of infection because there is no appreciable organic matter in them, upon which germs can thrive.

Vol. XVII. APRIL 5, 1917 No 14.

POSSIBLE EFFECTS OF U.S. ENTRY

IT IS a foregone conclusion that by the time this issue is in the hands of our readers, the Government of the United States will be formally committed to the prosecution of war against Germany. President Wilson's address to Congress on the evening of April 2, stated that any further avoidance of hostilities was impossible in view of Germany's actions, and included a number of specific recommendations whereby the States might best help the Allied cause.

Of prime importance to Canadian manufacturers is that urging all preparations to be made in such a way as not to check the flow of war supplies to the nations already in the field against Germany. Coupled with this recommendation are others advising utmost practical co-operation in counsel and action with Allied Governments, and extension of liberal financial credits to those Governments, so that the resources of America may be added so far as possible to theirs. In view of the immense volume of domestic business now being done in the States and the high degree of efficiency attained by Canadian munition plants, coupled with the fact that recent developments have caused a reduction in demand for certain sizes of shells hitherto made here, it appears not unreasonable to suggest that surplus Canadian capacity might very well be availed of by the States with a view to avoiding any more disturbance to domestic business than necessary.

The actual extent to which preparations have been carried by our neighbor has been surrounded by increasing mystery of late, and it may be taken that co-operation with the Allies to the extent desired by the President will not fail to include co-ordination of effort so that regular trade in the States will suffer the least possible dislocation from sustained military effort.

Early developments will show to what degree it is advisable and possible for the American nation to participate in actual hostilities. That they will be called upon to meet hostile forces on this continent armed with modern equipment, is extremely improbable, while the manner in which Britain has succeeded in arming herself and others discounts to a large degree the necessity for a feverish outburst of munitions manufacture by all and sundry. On the other hand, provided transportation was available, the supply of munitions on a large scale by the States would release many plants in Britain, so that serious efforts could be made by that country to regain lost trade and re-establish conditions which would have a permanent and ultimately more effective result in reducing the burden of war than would be the case otherwise.

The probability that the United States will raise funds by taxation instead of loans, accentuates the point brought up—that the necessity of maintaining a large trade volume in conjunction with the war-time treatment of tariff regulations, may well result in further accessions to Canadian munitions production.

ASCENDENCY OF BRITISH INDUSTRIAL INFLUENCE

CONSIDERABLE significance attaches to the action of the British Standards Committee, which recently decided to translate its specifications into French, Spanish and Russian, to give metric equivalents of English measures, and to issue the specifications at a much lower price than has hitherto been the case. Viewed in the light of present educational activity in Britain—increasing study of the Russian language and general intimacy with continental countries arising from existing conditions,—such action is indicative of a commercial awakening more significant as an event, and more far-reaching in its ultimate influences than any previous occurrence on parallel lines.

Further interest attaches to the statement that the Committee's decision was incorporated in the annual report of the Council of the Institution of Mechanical Engineers on the occasion of its seventieth annual general meeting in London. Members of the Society hold influential posts in all parts of the world and their natural desire to favor home regulations will receive considerable impetus thereby. The ever-increasing importance of the British mercantile marine and the duties discharged by the various supervisory bodies associated therewith, are two factors not without influence on the era of industrial activity presaged by recent happenings in the Western hemisphere.

Consideration of these incidents points to the fact that British influence, which has gained considerable ascendency in world affairs since August, 1914, will not be allowed to suffer any ultimate setback through lack of care and attention on the part of technical and commercial bodies. Latest advices from England state that the Government will assume control of any industry which it deems necessary, an action which will make a war works of the whole nation. The intensification of British standards and methods resulting therefrom, coupled with the present dependence of the Allies on Britain's finance and industry, may well insure the future status of Britain as the controller of the world's markets. Canadian manufacturers should avail themselves of every opportunity of familiarizing themselves with the actions and influences of Britain's industrial interests.

INDUSTRIAL NOTABILITIES

JAMES ANDERSON COULTER, president and managing director, John Morrow Screw & Nut Co., Ingersoll; president, Ingersoll Hotel Co., was born in Hastings County, Ont., Dec. 11, 1868, son of James and Mary A. (Hargan) Coulter. On the completion of his education which was received at the Collegiate Institute, Seaforth, Ont., Mr. Coulter entered the employ of John Morrow & Co., as shipper, advancing in successive stages to his present position with the firm which was afterwards organized as John Morrow Machine Screw Co., and later re-organized into John Morrow Screw & Nut Co., Ltd.

The civic activities of Mr. Coulter have been quite extensive, including a term as Mayor of Ingersoll, 1907-1908; member of Town Council, four years; member Board of Education, seven years, and as chairman, one year; member Board Alexandra Hospital; member of Executive, Canadian Manufacturers' Association. He was also a Delegate to Imperial Congress of Chambers of Commerce of the Empire at London, England.

JAMES ANDERSON COULTER

In 1892 Mr. Coulter married Elizabeth Maie Dundass, daughter of late William Dundass, Ingersoll, their family consisting of two daughters. His clubs are: National; Canadian; and Curling and Golf; also Ingersoll Amateur Athletic Association.

Affiliations and societies include, A.F. & A.M.; I.O.O.F.; and Canadian Order of Foresters. In politics, Mr. Coulter is Conservative, and in religion is Methodist, having been many times delegate to conference. The family residence is 2 Duke Street, Ingersoll, Ontario.

The General Market Condition and Tendency

THE steady advance in prices of steel products continues without any indication whatever as to when the crest of the movement is likely to be reached. The probability that the United States Government will be a heavy buyer of steel has stimulated the demand and is tending to force prices up. The situation in the States is being reflected in the Canadian market and higher prices on all iron and steel products may be looked for. Conditions at the mills have improved and production is increasing in a satisfactory manner. The freight congestion has been relieved materially, allowing a freer movement of fuel and raw materials. Manufacturers are thus in a better position to increase their output, although the shortage of labor is still a handicap. Prices of pig-iron in the States continue to advance and higher prices on Canadian foundry irons are looked for in the near future. Shipments of coke are heavier, due to the improvement in the car situation and increase in output at the ovens. Prices of scrap metals are holding firm at unchanged prices. The demand is confined principally to steel scrap and machinery cast iron. Gasoline, benzine and coal oil have advanced, the market being very firm. The demand for non-ferrous metals is light, and prices are unchanged with the exception of antimony, which has advanced. The metal markets are quiet, due to the unsettled International situation. The machine tool market is quiet and situation unchanged.

Montreal, Que., April 2, 1917.—The outstanding feature of the present industrial situation is undoubtedly the meeting of the American Congress to dispose of the long drawn out action on the part of that government, regarding the part they are to play in the present world crisis. The effect of the United States entrance into the war will tend to increase the strenuous efforts that steel producers have been making to supply the needs of home and export demand. Additional pressure on the furnaces and mills can only have one result, that of a further advance to higher levels. The consistent demand for shell steel and the great difficulty experienced in obtaining raw materials have resulted in the constant rise in the cost of pig iron which must naturally be transmitted to the steel products, so that any additional pressure placed on the producing plants must necessarily mean a corresponding advance in prices together with increased difficulty in the delivery of supplies. The early opening of navigation is expected owing to the favorable weather conditions, assisted by the activity of the government ice-breakers along the route of the St. Lawrence River.

Pig Iron

The upward movement in pig iron quotations continues and indications point to a still further advance. Bessemer heads the list this week with an advance on the Pittsburgh quotation of $2 per ton, the price being now $40.95 per ton. The latest advance brings the composite price of pig iron up to $37.06 per ton. The higher tendency in the pig iron situation will likely influence early conditions in the steel market.

Steel

The dominating feature in the steel situation is the uncertainty that characterizes the American market owing to the tension on all sides as a result of the coming developments. Whatever action the government may decide on, it is certain to have a stimulating effect upon all industrial circles. Should a declaration of war be the outcome of the present sitting of Congress, and America decide to take an active part in subduing the enemy, great impetus will be given to a large number of industries, and steel will again take an upward bound. This will in all possibility only affect the present market, as the American producers will likely follow the action of the copper interests, in supplying the requirements of the government at a price somewhat below that prevailing on the open market.

It is believed that delivery to present customers will be somewhat delayed in order that the more urgent needs of the government can be filled. Canada may experience greater difficulty in obtaining supplies from the States, and producers here should figure on increasing their facilities to meet the changed conditions. Although the congestion on the railroads is becoming less pronounced each day, there is still much room for improvement. The near approach of the opening of navigation will afford some relief in this direction, but the greatest drawback to maximum production of finished and semi-finished product, is the difficulty of producers to secure the raw materials, and the serious condition of the labor market, which in the event of war will still further add to manufacturing handicap. Few changes have been recorded in the general steel situation, but the further advance noted in this week's pig iron quotations, will likely be reflected in the early prices of various grades of steel. The demand for billets and sheet bars continues to be very heavy and the higher cost of basic metal may eventually mean still higher quotations on this grade of steel. Another factor tending to higher steel prices is the stronger position of ferro-alloys: the price of ferromanganese for prompt delivery having advanced $50 during the past week, the current quotation being $375 per ton. Price on fourth quarter delivery is now $300. Pressure on the plate mills reflects the future of this branch of the steel industry, one that will not be so easily affected by a sudden change in international relations. War possibilities would increase the tension under which these mills are working at the present time, while any easing up of hostilities would throw increased business toward the plate mills, in order to meet the ever increasing needs of the shipping interests. Canadian shipbuilders are making strenuous efforts to combat the tonnage question, by providing increased facilities for the production of vessels, but the greatest problem will continue to be the inadequate supply of plates for steel vessels. It is anticipated that the early future will bring about a revision in the price of sheets, as large producers are contemplating a move in this connection. The continued heavy demand for wire and its products may shortly mean a further advance in these lines: several sales are reported to have been made, at prices above those prevailing on the open market. Wrought iron pipe is still in heavy demand and definite delivery is practically impossible to obtain. Despite the recent advance in boiler tubes, the demand upon the mills is so insistent that users of these supplies are experiencing what might be termed a famine and even the offer of heavy premiums cannot induce the producers to satisfy the requirements of some customers. The sold up condition of the mills is such that definite delivery cannot be promised before the middle of next year. The local situation remains unchanged; the freight situation has become less serious but difficulty is still experienced in securing delivery of material.

Metals

The metal interests are anxiously awaiting the action of the U.S government, as their decision will greatly influence the early future policy of dealers and producers. The market generally has developed a weaker undertone with prices easier. Copper is responding to the quieting influence and quotations have declined. Tin continues to retain its average position with this week slightly easier than last. Spelter is dull and lower. Lead is firm but with a weak undertone. Antimony is stronger abroad but easier locally. Aluminum is steady and firm.

Copper.—Quiet prevails in the copper situation and the slackening off in the demand is principally due to the disturbed conditions arising out of the political movement in the United States. The tension is now at the breaking point and the present week promises some of the most interesting developments since the opening of hostilities. Whether the fact of the American Government securing copper at a figure greatly below the market price, will have the effect of producing an easier market, is at present problematical but the indications point to a decline in copper quotations. The London market has continued firm, but the situation in New York has shown a weaker tendency: lake having declined 1½ cent, and electrolytic one cent. Local dealers report a much easier position in copper with a slightly weaker demand; quotations show a falling off of 3½c on lake and electro., and 4½ on castings, the respective prices being 39½c for lake and electro, and 38½c for castings.

Tin.—While a weaker tone has developed in tin, the situation is nevertheless comparatively firm. The market is still influenced by the ever present possibility of loss in transit, and the unsettled condition across the line tends to put dealers on their guard, as early developments may create an unprecedented situation in industrial circles. Considerable interest is centered in the higher prices quoted on straits tin, and the possibility of a curtailment in the supply. Easier conditions prevail both in London and New York, the latter having declined 1¾c on the week, the current quotation being 54½c per lb. The local situation has developed a weaker tendency on a quiet market, the quotation of 55½ being a decline of one cent per lb.

Spelter.—Absence of interest has resulted in a dull market and an undertone of weakness seems to prevail, although what little business is passing is done at firm prices. The principal factor in the maintenance of present high prices is the zinc ore situation, which in many respects, is the controlling feature of the spelter market. Early future conditions will be governed to a great extent, by the developments of the next few days, when the action of the United States authorities has been definitely decided on. New York quotations this week are about 10¾c this price being ⅛ cent below that of the previous week. Dealers here report an easier tone on a decline of ½ cent per lb. the price asked being 15c per lb.

Lead.—The falling off in demand has somewhat weakened the lead situation, but the strength is being well maintained owing to sold up condition of the producers. This fact alone is the reason of the high market as the requirements of the trade at the present time are considerably below the production figures. Should the needs of the U.S. government necessitate supplies of lead, it is anticipated that metal will be supplied upon similar conditions to those furnished by the copper interests. The easier tendency is reflected in the slight decline of outside quotations, although the leading interests continue to hold firm. Trust price steady at 9c, with independents quoting 9¾c, this latter price being ⅛ cent lower than last week. The local market continues firm with prices unchanged at 12¼c per lb.

Antimony.—The demand for this metal is very good and unexpected arrivals have had a contrary effect upon the situation, as dealers are apparently impressed with the higher value of spelter and consequently quotations have moved upwards. Conditions at the present time however, are such as to give no clear indications as to the near future, and the trade would not be surprised to see another reversal before the week closes. The current price of 36c on the New York market, shows an advance over last week of 2c per lb. On a weaker market dealers here are quoting 28c per lb., a decline of 2 cents over last week.

Aluminum.—The demand for aluminum is not heavy but the market continues to maintain its strength, the local quotation remaining firm at 70c per lb.

Machine Tools and Supplies

Activity in the machine tool industry is gradually assuming more general proportions and conditions, as the business that is passing is less of a shell nature than that of several weeks ago. A fair volume of business is still being done in single tools for munitions work, but even this has somewhat fallen off. A feature of the machine situation in the States is the anxiety that is displayed by tool builders, regarding the early effects that a declaration of war will have on this industry. While considerable used machinery is offered for sale, many firms equipped for shell making are apparently awaiting current developments before disposing of their equipment. War conditions will stimulate the production of machine tools, and result in a return to greater activity along these lines.

Scrap

The first part of the week was comparatively quiet in old metals, but the activity showed some improvement towards the close. Prevailing conditions tend to uneasiness in all branches of industries and that of scrap has been similarly affected. Local dealers in old material are awaiting the week's developments before adjusting their quotations. The changes this week are confined to heavy melting steel and wrought iron axles; each having been marked up one cent per lb., the respective quotations being 17 and 22c per lb.

Toronto, Ont., April, 3.—The eminently satisfactory trade conditions now prevailing in Canada are clearly shown in a statement recently issued from Ottawa covering the revenue for the fiscal year which closed last Saturday. Although the exact figures are not yet available, the statement shows that the trade of the Dominion for the fiscal year just closed was approximately twice in value that of the preceding year. The ordinary revenue of the Dominion for the year just closed amounted to approximately $230,000,000, or $100,000,000 more than that of 1914-15.

Steel

The situation in the steel trade continues to get tighter, and prices are still going up. Recent reports of the steel companies all reveal the unusually satisfactory conditions prevailing in the industry, and indications point to continuance of prosperity for the remainder of this year at least. The improved weather conditions have been favorable to the transportation of raw materials and the situation in this regard is more satisfactory than at any time this year. Although the output of the mills has increased materially during the past two or three weeks, deliveries are not keeping up with orders, and consequently are getting further behind. The recent advance in wrought pipe in the States has been followed by a similar movement here. The advance is equivalent to about $4 per ton and affects both black and galvanized pipe. Prices on boiler tubes are practically nominal as supplies are very scarce owing to the heavy demand and sold up condition at the mills. The demand for ship plates continues very heavy and indications point to the situation becoming more acute even in the near future. It is understood that the Imperial Munitions Board has placed orders for large tonnages of ship plates. Prices are practically nominal and substantial premiums are being paid for early deliveries, in fact the price depends largely on delivery required. The recent advance in price and growing scarcity of wire rods will doubtless result in higher prices on wire products in the near future. Advances in rivets, spikes, bolts and nuts may also be looked for in the near future.

Prices of Canada plates have advanced due to increase in cost of raw material. The demand for black sheets continues very heavy. Production on sheets is steadily increasing, but some mills are experiencing considerable difficulty in obtaining sheet bars, deliveries in consequence are generally backward. The situation in the galvanized sheet trade is improving, but there is no sign of lower prices.

The steel trade in the United States continues very active the volume of business being very heavy. The expectation that the U.S. Government will soon be in the market for further heavy tonnages of steel is tending to stiffen prices. Open hearth sheet bars are now being quoted at $72.50 per ton, and tank plates $5.50 per 100 lbs. Pittsburgh.

Pig Iron

The pig iron market continues very strong and prices are still advancing in the States. The ruling price at Buffalo for foundry irons for current and last-half delivery is $40 furnace, with a range of $39 to $40 from the lower to the higher grades. Prices on domestic foundry pig iron are unchanged at $43, but an advance is looked for any time. A report from Pittsburgh states that enquiries are pending for from 10,000 to 20,000 tons of foundry iron for shipment to Canada. The following prices are now being quoted on leading grades of pig iron in the U.S. Grey forge, Pittsburgh, $34.95; Lake Superior charcoal iron, Chicago $38.75; Basic Valley furnace $35; Bessemer, Pittsburgh, $30.95.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Scrap

The situation in old materials continues practically the same as last week. Prices although unchanged are holding firm. Interest centers principally on steel scraps which are in good demand particularly for heavy welding steel. Supplies of steel turnings are plentiful and are in excess of the demand. Copper, brass, and lead scrap, are in fair demand at unchanged prices.

Machine Tools

There is no appreciable change in the machine tool situation. There is still a fair demand for equipment for munitions plants, mostly for single tools. An aeroplane factory is in the market for machine tools which has helped to stimulate business. More second-hand equipment continues to come on the market from plants which have given up making munitions in the States.

Supplies

Gasoline, coal oil and benzine have advanced one cent per gallon, which brings gasoline up to 31½c per gallon, and benzine 1c lower. Coal oil, "Royalite," is 16c a gallon. Putty has advanced 25c and is now quoted at $4 per 100 pounds in drums.

Metals

There is a quiet tendency in the metal markets due to a disposition to await developments in the International situation. The undertone however is firm and an upward movement in prices will likely develop now that the U.S. Government has decided to take an active part in the war. Prices are unchanged with the exception of antimony which has advanced due to a scarcity of this metal.

Copper.—The market is quiet and prices have an easier tone due to the appearance of re-sale copper on the market offered at concessions. Buying of copper for deliveries near the end of the this year is increasing. Prices are nominal and unchanged. Lake and electrolytic copper are quoted locally at 40c, and castings at 39c per pound.

Tin.—Prices of tin continue to be nominal, and the market is quiet although somewhat firmer. The London market has been advancing steadily for some days, but New York prices are unchanged. Tin is quoted locally at 56c per pound.

Spelter.—The market is dull but firm. Prices of spelter depend upon developments in the zinc ore situation, as the margin of profit is now very fine. A change one way or the other in the price of ore would likely be reflected in quotations on spelter. Local price is 14c per pound.

Lead.—There is no change in the lead situation and nothing to indicate any marked change in prices in the near future. Lead is quoted locally at 12¼c per pound.

Antimony.—Quotations are nominal and higher due to a scarcity of spot metal. Local price is 36c per pound.

Aluminum.—The market is dull and prices unchanged at 68c per pound.

Sydney, N.S., March 30. The Minister of Labor has declined to grant a Board of Conciliation on the application of the U.M.W. of Nova Scotia, purporting to represent a section of the workmen at the colleries of the Dominion Coal Co., for the reason that the question of a wage increase, which was given first place in the list of grievances preferred by the U. M. W. of Nova Scotia, was a matter already under discussion between the Dominion Coal Co., and its workmen as represented by the Provincial Workmen's Association. This last-named organization has entered into a wage contract with the company that does not expire until the end of 1918, and under the terms of this contract, the company granted a wage increase of six per cent. in May, 1916, to be followed by a further 4 per cent. increase on the 1st of January, 1917.

This last-named increase was, however, anticipated and made effective at the 1st of November last, and in addition the company granted a war bonus of ten per cent., making a total increase over the wages paid previous to May.

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

1916, of 21 per cent. Further, and in addition, the company granted a bonus of 5 per cent. to all producers who worked 22 days out of each working period of 24 days, with a view to encouraging production. This brought the wages of producers up to 26½ per cent. above those of May, 1916. The P. W. A. have now preferred a request for a further 30 per cent. increase, which, if granted would make wages 57 per cent. above those of May, 1916, and in the case of those who earned the steady work bonus, would represent an increase of no less than 65 per cent. The Coal Co. have refused to grant an increase of such magnitude, and it is understood the P. W. A. have asked for a Board of Conciliation, which, in view of the decision of the Minister of Labor in the case of the U. M. W. of Nova Scotia, will in all probability be granted.

The Minister of Trade and Commerce has called a meeting on the 2nd of April at which the attendance of the coal operators of Nova Scotia is asked to consider the question of coal supply and transportation. It is not generally realized how great a change has taken place in the percentages of distribution of Nova Scotian coal as compared with pre-war times. Before the war the quantity of coal used at the steel works in Cape Breton, in colliery consumption, local domestic sales and supplied at home ports to steamer bunkers, would average 30 per cent. of the coal production. To-day the coal consumed locally amounts to 65 per cent. of the total protion of the collieries.

As an example of the reversal of some of the figures it may be stated that in 1914 the shipments of the Dominion Coal Co. to the St. Lawrence markets represented 44 per cent. of the total disposal of the company's production. In 1916 the St. Lawrence percentage had dropped to ten per cent., and in 1917 it may not exceed 3 per cent. There is no way by which the production of the Nova Scotia coal mines can be increased except by bringing the miners back from the front, and the only way in which the continuous decline in production can be stopped is to prevent any further enlistment of miners. The normal coal production of Nova Scotia should be 7¼ million tons per annum. In 1917 the production will be between 5½ and 5¾ million tons, provided no accidents or stoppages of work take place. Government action in this matter is long overdue.

Construction work will very shortly be commenced on new coke-ovens for the Dominion Iron & Steel Co. at Sydney. It is understood the contract for the erection of the ovens has been let.

The Jones Underfeed Stoker Co., have removed their office from the National Trust Building King street, East, to 37 41 Britain street, Toronto with increased facilities for catering to the requirements of their customers.

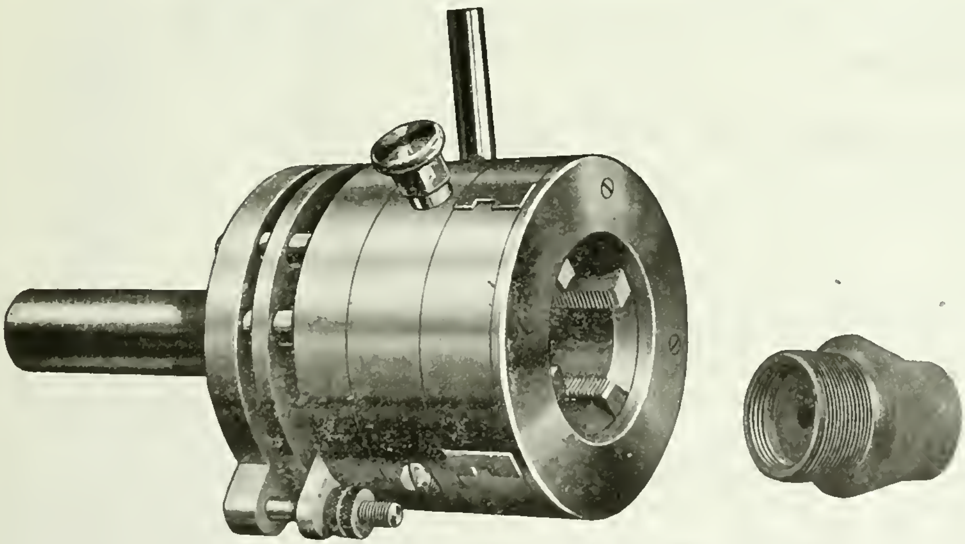
"The Die Head That Thinks"



GEOMETRIC STYLE "D-D"

With such precision does the Geometric Style "D-D" Die Head perform every action, it has been called the Die Head that thinks.

Compensating springs give perfect threads at the start, and cause the dies to follow the lead properly. The head will float in either direction. On heavy turrets it is not necessary for the operator to follow the thread closely. Fine adjustments can be made for length right in the Die Head itself, without changing the stop on the machine

The Style D-D Die Head illustrated above is cutting a 2-inch, 14 thread on fuse plugs, on a hand-operated turret.

Are you among the small minority of screw-thread makers who have not discovered Geometric advantage?

The Geometric Tool Company, New Haven, Conn., U.S.A.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

London, Ont.—The Middlesex Mills Co., are building a boiler house at their plant here.

Regina, Sask.—The Standard Tractor Co. has secured a site on which a plant will be erected soon.

New Hamburg, Ont.—The Dominion Thresher Co. has taken over the plant of the Hamburg Thresher Co.

Smelter Junction, B.C.—The C. P. R. proposes to build a round-house, shops, etc., at Smelter Junction, B.C.

Lindsay, Ont.—The Boving Hydraulic and Engineering Co., are considering building an extension to their plant.

Kitchener, Ont.—The Canadian Consolidated Rubber Co., will build a machine shop here. The Austin Co. of Cleveland, O., are the engineers.

Toronto, Ont.—Plans have been prepared for a new foundry to be erected on Cherry Street by the Queen City Foundry Co., at a cost of $12,000.

Toronto, Ont.—A building permit has been issued to the Cluff Ammunition Co., 28 Atlantic avenue for a temporary saw shop, $1,000, and storage shed $1,000.

Kitchener, Ont.—V. O. Phillips & & Sons have started the erection of an addition to the plant of the Twin City Oil Co., for the manufacture of a gasoline pump.

North Bay, Ont.—The Temiskaming and Northern Ontario Railway Commission propose building here a mechanical coaling plant to cost $27,000 and a machine shop extension, $15,000.

Halifax, N.S.—A new company has been formed which will be known as the Halifax Steel Co., to take over the Nova Scotia Car Works, Louis N. Fuller of Halifax is the moving spirit in the new enterprise.

Toronto, Ont.—Good progress is being made on the new steel plant at Ashbridge's Bay. The pile drivers are preparing the site and the Hamilton Bridge Works have started erecting one of the buildings.

Windsor, Ont. — Goldman & Harris who proposed to establish a brass foundry here may build the plant in some other town as the City Council has raised the price of the site from $850 to $1150 per acre.

Bedford, Que.—High water in the river carried away the dam on March 26, causing considerable inconvenience to the Bedford Light, Co., Bedford Stove Co., and Corey Needle Co., who obtain their supply of light and power from this dam.

East Angus, Que.—The Brompton Pulp & Paper Co. are building a power plant about five miles below the mill. The power will be used to increase the capacity of the mill and replace some steam power being used at present. The cost of the development is estimated at $200,000.

Fort William, Ont.—Mayor Murphy announced at the council meeting recently that the Canadian Car & Foundry Co. would operate their plant here, this spring. W. S. Attwood had just completed an inspection of the plant, which can be completed in ninety days, and partially operated as soon as material can be brought here.

Windsor, Ont—Fire of unknown origin last Friday night completely destroyed the Canadian plant of the Chalmers Motor Co., located in Ford. The loss is placed at a quarter of a million dollars, fully covered by insurance. The Chalmers' plant, a branch of the parent concern in Detroit, was established about seven months ago.

GENERAL

Wallaceburg, Ont.—The Dominion Glass Co., will build an extension to their factory.

Montreal, Que.—The Imperial Tobacco Co., will build a large extension to their factory here.

Moose Jaw, Sask.—The Robin Hood Milling Co., will build an extension to their mill here.

Niagara, Falls, Ont.—The Perfection Tire Co. of Chicago, Ill., contemplate building a factory here.

Hamilton, Ont.—The Furnival-New Co., jam manufacturers, will build an extension to their plant, to cost $5,000.

Toronto, Ont.—The manufacturing building at 35-45 Lombard street was damaged by fire on March 27 to the extent of $30,000.

Petrolea, Ont.—The work on the flax mill, which was partly built last year, has been resumed and will soon be completed. Contracts for flax are being made with farmers.

Winnipeg, Man—Charles Midwinter, land settlement agent of the Greater Winnipeg Water District, plans to develop extensively the sugar beet industry along the Shoal Lake Railway this season.

Markham, Ont.—At the recent fire at W. & G. Pringle's wagon works the plant destroyed at a loss of $5,000, after receiving about $1,000 insurance. It is not expected that the wagon works will be rebuilt.

Wallaceburg, Ont.—A new canning factory of the Ontario Canners is expected to start here to be run six months of the year. The factory, which is close to the Pere Marquette station, will be the head office of the Ontario Canners.

North Bay, Ont.—The Town Council has decided dto submit a by-law to the ratepayers authorizing the guaranteeing of bonds for the sum of $15,000 to the J. P. Quinlan Manufacturing Co. The concern intends to manufacture furniture, school and church fittings, etc.

Guelph, Ont.—The firm of Fried, Grill & Co., of Toronto, hat manufacturers, have decided to locate here. The factory they will occupy is the one at present occupied by Libby, McNeil and Libby, and which is the property of the city. They have paid $2,000 and the city takes a first mortgage of $6,000 for the balance.

MUNICIPAL

Sidney, N.S.—The City Council may purchase fire alarm boxes, and motor driven fire equipment.

Trenton, Ont.—The Town Council have under consideration an extension to the water supply system.

Peterboro, Ont.—The City Council contemplate the purchase of combined motor-driven pumping engine and hose wagon.

Hamilton, Ont.—The Board of Control will buy a motor tractor and pump for the fire department at a cost of $12,000.

Redcliff, Alta.—An expenditure of $30,000 is contemplated for alterations in the present pumping station and installation of adequate machinery. A by-law will be submitted to ratepayers.

Sherbrooke, Que.—The by-law submitted to the rate-payers on March 26, providing for the purchase of the Two Miles Falls power plant on the St. Frances River at Weedon, at a cost of $375,000, was carried by a large majority.

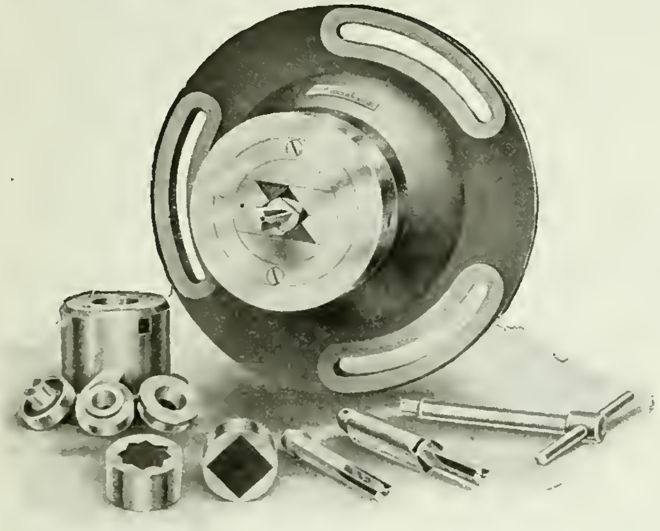
Wolseley, Sask.—A by-law will be submitted to the ratepayers on April 7 to authorize an expenditure of $9,000 for the purchase of a gas engine, dynamo, building and site, etc., for municipal electric light plant. A. B. Hill, secretary-treasurer.

Sudbury, Ont.—On April 30 a by-law will be voted on by the ratepayers to sanction an expenditure of $46,000 for stand pipe and auxiliary main, and $2,500 for alterations to lake sewer pumping station. W. J. Ross, town clerk.

Hilldale, Ont.—A by-law will be voted on by the ratepayers on April 16 to authorize an expenditure of $2,500 to purchase and instal a gasoline engine and appliances for supplying electric light in the police village of Hillsdale. T. D. Robinson, township clerk, Moonstone, Ont.

Aikenhead's RADBORE HEAD

Drills Square Holes Accurate

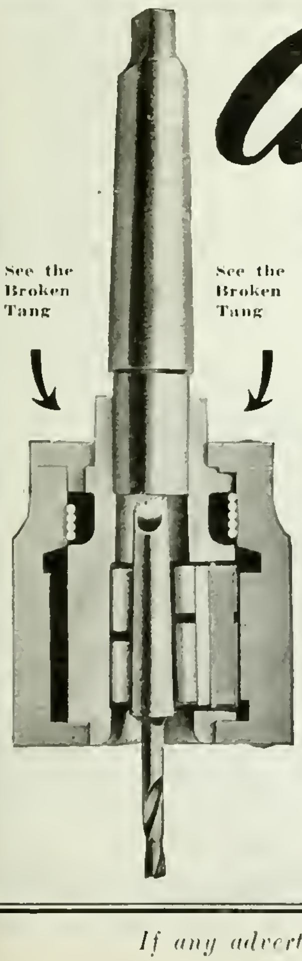


MAXIMUM ACCURACY--MINIMUM COST

Radbore Heads will drill square holes through the material or they will drill square holes to any desired depth with perfectly flat bottoms! Once in your shop the uses that spring up for this head will be remarkable.

Aikenhead Hardware Limited
17, 19, 21 TEMPERANCE STREET, TORONTO

Aikenhead's New Chuck



Did you know that the tang was unnecessary?

Perhaps you are about to discard some taper shank drills because the tangs are broken off—**don't do it** they are worth their weight in gold. You can use them just as they are with a

Wahlstrom Automatic Chuck

For Nos. 1, 2 or 3 M. T. Shank Tools

and you won't have to take time from your production to repair them.

Tool changes are made in two seconds—just grasp the shell of the chuck with one hand and put in or remove the tool with the other—no collets—no lost time, for the spindle never stops.

The jaws hold **not the tang, but the entire** shank—there's no chance for slippage—a Wahlstrom won't even mar the shanks.

There are also three sizes of Wahlstroms adapted for straight shank tools—have you heard the story? Better write for it to-day and we'll explain our trial offer.

Aikenhead Hardware Limited
17, 19, 21 Temperance Street - Toronto, Canada

ELECTRICAL

St. Catharines, Ont.—The Hydro-Electric Commission of St. Catharines have decided that in order to give the residents of this city the best possible service a new line must be built to the city from Niagara Falls. This line will be started immediately.

TENDERS

Regina, Sask.—The City Council are receiving tenders for a centrifugal pump and motor.

Terrebonne, Que.—The Town Council are calling tenders for a shoe factory. The plans and specifications of this building can be seen in the office of Dupont Roy & Beaudoin Engineers, 225 St. James Street, Montreal.

Montreal South, Que.—Tenders will be called sometime in April, for a 30-h.p. motor-driven turbine pump and a 150-h.p. gasoline engine-driven turbine pump for fire purposes, etc. E. Drinkwater, St. Lambert, Que., is the engineer.

Toronto, Ont.—Tenders will be received for a building until April 9, addressed to the Toronto Harbor Commissioners, 50 Bay Street, Toronto, Ont. All information may be obtained by applying to the Architects, Chapman and McGiffin, 95 King Street East, Toronto.

Greenfield Park, Que.—Tenders will be received until April 12 for the following:—Copper wire, transformers, street brackets, tungsten lamps, line construction material, meter.. Specifications may be obtained on application to W. G. H. Cam, 3 Beaver Hall Square, Montreal.

Toronto, Ont.—Tenders will be received by Frank Barker, Engineer for the Township of York, up to April 14, for the supply and delivery of 24-inch stop valves and hydrants. Plans and specifications may be seen, and all necessary information obtained, at the office of the engineer, 57 Adelaide Street, East, Toronto.

Winnipeg, Man.—Tenders, addressed to the Chairman, Board of Control, will be received up to April 16, for the supply of labor and materials required in the erection of a 150 foot brick or concrete chimney for the Elmwood Incinerator. Plans, specification and form of tender may be obtained at the office of the City Engineer, 223 James Avenue.

Winnipeg, Man.—Tenders addressed to the Commissioners of the Greater Winnipeg Water District will be received up to April 16, for the supply of miscellaneous bronze castings, brass piping, etc., which enter into the construction of a Venturi meter. Specifications and form of tender may be obtained at the offices of the district, 501 Tribune Building, Winnipeg.

Winnipeg, Man.—Tenders addressed to R. D. Waugh, Chairman of the Commissioners, Greater Winnipeg Water District, up to April 16, for the supply of approximately 12,000 feet of 48-inch and 1,300 feet of 60-inch cast iron pipes, together with numerous specials and gate valves. Specifications may be obtained upon application to the offices of the District, 501 Tribune Bldg., Winnipeg.

Winnipeg, Man.—Tenders, addressed to the chairman, Greater Winnipeg Water District Commission, at 501 Tribune Building, Winnipeg, will be received up to April 16, for the supply of one second-hand passenger coach, also one second-hand caboose, both standard gauge. Tenderers to supply own specifications. Further particulars on application to undersigned. R. D. Waugh, Chairman of Commissioners.

Ottawa, Ont. — Tenders will be received until April 21, for steam boilers and stokers required for the Central Heating Plant for the Parliament Buildings. All tenders to be based on the supplying and erecting of three water tube boilers, each having a rated capacity of 500 horse power, together with fittings and soot blowers. Each tender shall give separate quotations for supplying and erecting, in connections with boilers, three automatic stokers. One boiler and stoker shall be erected complete within five months after date of awarding contract and the other two shall be erected before January 1st, 1918. Plans, specifications and any other information required can be obtained at the office of the general contractor, P. Lyall & Sons Construction Co., Ltd., Ottawa.

CONTRACTS

The Phoenix Bridge & Iron Works, Montreal, have been awarded the contract for steel work for the $45,000 steel bridge across St. Francis River at East Angus, Que.

The Roelofson Elevator Works, Galt, Ont., have been awarded the contract for elevator equipment for the two-storey addition to the factory of the Gummed Paper Co., at Brampton, Ont.

Windsor, Ont.—The contract for the new bridge on Wyandotte Street over the M. C. R. has been awarded to J. V. Gray & Co. for $14,730. Other bidders were: Wells & Gray, $15,030; R. Westcott, $17,279.

PERSONAL

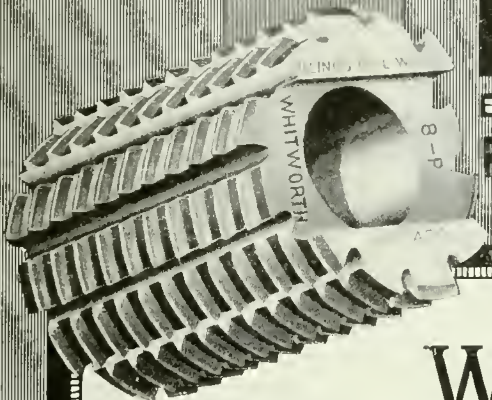
W. F. Tye, of Montreal, has been engaged by the city of Hamilton, Ont., to report on a common railway terminus. Mr. Tye will start work at once.

Capt. E. T. Sterne, of Brantford, Ont., has been appointed chief inspector and resident technical adviser to the Imperial Munitions Board at the new plant of the British Chemical Co., Trenton, Ont.

James A. Stairs, vice-president of the Eastern Steel Co., New Glasgow, N.S., has recently been in Ottawa on a business trip, more particularly in the direction of securing orders for shipbuilding which his company propose to undertake.

Charles H. Waybrant, who for the past six years has been with the Steel

ILLINOIS HOBS



PRODUCE PERFECT THREADS

WHY not add the efficiency of ILLINOIS Tools to your equipment? ILLINOIS Hobs and Cutters can be relied upon for uniform accuracy and maximum output; they are of substantial advantage to the factory running to capacity in the production of work which must meet exacting specifications.

ILLINOIS TOOL WORKS

MANUFACTURERS AND DESIGNERS OF

CUTTERS - HOBS - REAMERS

CHICAGO U.S.A.

CANADIAN REPRESENTATIVE: Allan B. Wearing, Canadian Pacific Railway Building, Toronto

Company of Canada, at the Toronto office, has joined the staff of Baines & Peckover, iron and steel merchants, 98 Esplanade E., Toronto.

Hugh Russel, a life-long resident of Montreal, died on March 22 at his residence, 423 Guy street. Mr. Russel was president of Hugh Russel & Sons, Ltd., iron and steel merchants, Place d'Armes, and had been in business for himself in this city since 1868. He was born in Montreal on August 17, 1844.

Col. J. D. Stewart, who has performed useful service at the front, and has been placed in command of railway construction work for the allies in France, has also been promoted to the rank of brigadier-general. He is a well-known Canadian railway contractor, a member of the firm of Foley, Welch & Stewart.

Charles H. Easson, vice-president of Brown's Copper and Brass Rolling Mills, Ltd., formerly manager of the Toronto branch of the Bank of Nova Scotia has been appointed general manager of the Standard Bank of Canada, to fill the vacancy caused by the death of the late George P. Scholfield. Mr. Easson will assume his duties on April 2.

Dr. David H. Browne, widely known throughout the United States and Canada as a metallurgist of note, died at his home in Montclair, N.J., on March 30. He was 52 years old. In 1891 he joined the forces of the newly-organized Canadian Copper Co., and it was in the service of this concern that he brought about great improvement in the refining of metals and added much to the knowledge of metallurgy in this country and in the world. Dr. Browne was a member of the Canadian Mining Institute and many other engineering societies.

BUILDING

Toronto, Ont—A building permit has been issued to the Wm. Neilson Co. for a warehouse to cost $3,295.

Toronto, Ont.—City Architect Pearse has issued a building permit to the Dominion Glass Co., for a $5,000 addition to their factory at the foot of Dovercourt road.

Windsor, Ont.—Gilbert Jacques, architect, is working on plans for a new service and sales building for the Studebaker Corporation, which will be erected at the corner of Chatham and Pelissier. It will be a three-storey structure of brick, steel and concrete, 50 by 80 feet. The building will be fireproof, and will cost about $30,000.

MARINE

Montreal, Que.—Extensive improvements at the Canadian Vickers shipyard are now approaching completion. New berths and other extensions which have been undertaken at an estimated cost of $1,000,000, are expected to be entirely completed by May 15.

Victoria, B.C.—The auxiliary schooner Laurel Whalen was launched at the Cameron Genoa Mills shipyard on March 24. The christening ceremony was performed by Miss Marjorie L. Brewster, daughter of Hon. H. C. Brewster, Premier of British Columbia.

Collingwood, Ont.—During last week a fire broke out in the Northern Navigation Co's. steamer Germanic, which was burned to the water's edge. The Germanic was a wooden steamer, and was built in 1899. She was 184 feet in length, 23 feet beam, and 12 feet in depth.

Halifax, N.S.—An Act for the encouragement of shipbuilding in Nova Scotia has been introduced in the Legislature. The bill authorizes the appointment of a commission to investigate the existing facilities for building ships and manufacturing industries incidental thereto.

Montreal, Que.—Lachine Canal officials will shortly be very busy preparing for the opening of navigation. On April 7, the water will be run off, and a thorough inspection made of the canal bottom and lock structures. This will probably occupy a week, and it is the intention to admit the water again on April 15, in time for the opening of navigation.

TRADE GOSSIP

The E. J. Woodison Co., foundry outfitters have moved from 340 Dufferin street to more commodious premises at 858 Dupont street, Toronto.

Russians Buy Freighter on Great Lakes.—The steamer Nevada of the Goodrich Line, built at a cost of $275,000 in 1916 to carry passengers between Milwaukee and Chicago and equipped for winter traffic with ice-breaking bows, was recently sold to representatives of the Russian Government for $750,000. It will be used in the freight trade to Russian ports. The steamer will go to the Atlantic by the Welland Canal this spring and probably will be used to carry munitions to Russia.

Length of Freight Trains.—The Dominion Railway Commission has decided that under existing conditions it would not be justified in fixing a maximum length for freight trains. The commission on its own motion took up the question and heard the views of the railways and railway employees. Commissioner McLean, who writes the decision, holds that until the war is over the expeditious movement of freight should be the first consideration. When the war is over the question of regulating the length of trains will be taken up again.

Welland Canal Work Suspended.—Blasting on section 3 of the Welland Ship Canal to prevent the accumulation of water which has continued during the winter has been completed, and the Rock taken to Port Weller to hold the earthen breakwater embankment in place. Work on the big undertaking is now at a standstill, and will remain so until the end of the war. Thirteen locomotives owned by Baldry, Yerburgh & Hutchinson, contractors for section No. 2, have been secured by the Government, and are to be sent to France for military construction work.

New Freight Schedule in Effect Shortly.—The time for filing objections to the new freight classification expired last Friday, and G. C. Ranson, Chairman of the Canadian Freight Association, says the railways will make every effort to bring the new classification, with such amendments as the Railway Commissioners may think proper to make, into effect as soon as possible. The classification has been in contemplation for a number of years, and railway officials have been working on it for two years and a half, the final draft having been sent to the Railway Commissioners, on July 15, 1916.

Australian Elevator Order for Montreal Firm.—The State of New South Wales is about to erect at various points throughout the State, approximately 200 wheat elevators. The cost of the whole scheme will be $10,000,000. The Government of New South Wales has entered into arrangement with the well-known Montreal firm of John S. Metcalf & Co. to prepare a report, plans, and to supervise the work. The plans have been prepared by Metcalf & Co. at a cost of$100,000, and the work of supervision is to be paid for at the rate of one and a quarter per cent. on the cost of the elevators—about $125,000.

Will Launch Big Freighter.—Preparations have been completed for the launching to-day, Thursday at Collingwood, Ont., of the steel steamer Westmount, building for the Montreal Transportation Co. The Westmount is a sister ship to the J. H. G. Hagarty, is 530 feet in length, has a beam of 58 feet and a depth moulded to 31 feet. She has a gross tonnage of 7,500 and will carry about 11,000 tons of cargo. It is expected that the Westmount will go into commission about May 1 and will operate on the Great Lakes between Fort William, Port Arthur, Georgian Bay ports, Port Colborne and Buffalo.

Canadian Westinghouse Co. Elects Officers.—At the annual meeting of the Canadian Westinghouse Co., held at Hamilton on March 27, the following elected to the directorate of the concern: H. H. Westinghouse, Hon. Lieut.-Col. Paul J. Myler, L. A. Osborne, Thomas Ahearn, Sir John M. Gibson, K.C.M.G., John F. Miller, C. F. Sise, Warren Y. Soper, Charles A. Terry, Guy E. Tripp. The officers are: H. H. Westinghouse, chairman; Hon. Lieut.-Col. Paul J. Myler, president and treasurer; L. A. Osborne, vice-president; F. A. Merrick, vice-president and general manager; John H. Kerr, secretary; N. S. Braden, manager of sales.

The Turbine Equipment Co., Toronto, has been awarded a contract by the town of Strathroy, Ont., for one multi-stage De Laval centrifugal pump, which will be direct connected to a Canadian Westinghouse 125 h.p. motor; the capacity will be 1,000 Imperial gallons a minute, against 252 ft. total head. They have also been awarded through the Hydro-

Electric Power Commission of Ontario one De Laval single stage, centrifugal pump, which will have a capacity of 5,000,000 Imperial gallons a day against 210 ft. total head. This pump is for the City of Kingston, Ont., and will be direct connected to a 380 k.v.a. Canadian General Electric 1,200 r.p.m. synchronous motor.

Railway Commission Report.—The report of the commission on the Canadian railroad situation will be ready for Parliament soon after the reopening, April 12. It is generally understood Sir Henry Drayton and W. M. Ackerworth, the English financial expert, favor the application of a degree of nationalization to the Canadian Northern and the Grand Trunk Pacific. The third member of the board, A. H. Smith, president of the New York Central, does not favor nationalization, but takes the view that the best interests of Canada will be served by keeping the C.N.R., the G.T.P. and the C.P.R. under separate corporate control competing with each other with rates and operation regulated by the railway commission.

Trade in Canada Almost Double.—Canada's fiscal year closed on March 31. Exact figures for its operations will not be available for a few days, but it may safely be stated that when they are published they will show the revenue of the Dominion in 1916-17 to have been the largest in its history. They will also show the trade of Canada to have been nearly twice that of 1914-15. The ordinary revenue of the Dominion, it is stated, in the twelve months which ended on Saturday, amounted to about $230,000,000, or $100,000,000 more than that of 1914-15. The revenue of the past year will be sufficient to meet all the ordinary and capital expenditures of the country, and, in addition, pay fifty or sixty million dollars of the expenditures for war purposes. The total trade of the Dominion will be found to have reached about two billion dollars, or a billion dollars more than that of the fiscal year in which the war began.

Conference of Shipbuilders. — Sir George Foster, acting Prime Minister, held a conference at Ottawa on March 28, with the representatives of a number of Canadian shipbuilders, who are building ships in Canada for the British and Canadian Governments. The object of the conference was to discuss plans to systematize and speed up construction. The programme as already announced includes ships to the value of $25,000,000 being built for the British Government under the authority of the Imperial Munitions Board, as well as a number of vessels being built for a Canadian Branch of the Government Service. The contractors are also to report to the Acting Prime Minister that good progress is being made although some difficulty has been encountered in procuring steel. It is understood, however, that this is being overcome. It is stated in this connection that another big British shipbuilding company is likely to establish a branch shipyard in Canada.

INCORPORATIONS

The Port Arthur Pulp & Paper Co. has been incorporated at Toronto, with a capital of $2,000,000, to manufacture pulp and paper at Port Arthur, Ont. The incorporators are: George H. Sedgewick, James Aitchison and Duncan McArthur, all of Toronto.

The London Smelting & Refining Co. has been incorporated at Toronto, with a capital of $45,000, to carry on the business of refiners and smelters of all kinds at London, Ont. The incorporators are: Jacob Harris, Samuel Harris, and Louis Harris, all of London, Ont.

The Bawden Pump Co. has been incorporated at Toronto, with a capital of $40,000, to carry on the business of engineers and founders, including the manufacture of pumps of all kinds at Toronto. The incorporators are: G. H. Sedgewick, James Aitchison, and Duncan McArthur, all of Toronto.

RAILWAYS—BRIDGES

Montreal, Que.—The Merchants Bank of Canada has sent in an application at Ottawa to the Railway Commissioners for an order approving of the sale of the rolling stock, equipment, charter and other accessories of the Joliette & Lake Manuan Colonization Co.

Bloomingdale, Ont.—On March 24, representatives from the Kitchener City Council and from Guelph met a number of citizens of this locality, with whom they discussed the proposed Kitchener to Guelph via Bloomingdale and New Germany electric railway. The meeting was unanimous in favoring the scheme.

Montreal, Que.—New tenders have been called for by the Board of Control for the Lasalle bridge over the aqueduct, connecting Verdun with the city of Montreal. This action follows the withdrawal from his contract of T. O'Sullivan, who contracted to build the bridge in the first instance. In the meantime, pending the making of fresh bids, the city is holding Mr. O'Sullivan's deposit of $25,000 which he made as security for fulfilling his contract.

WOODWORKING

Sarnia, Ont.—The Cleveland Sarnia Saw Mills opened on Monday after being closed since last fall, when logs were frozen in the bays. About 200 men have been put to work.

Elmira, Ont.—The Elmira Transmission Co. will erect dry kiln, moulding shop, and machine shop on Church St. A by-law will be submitted to the ratepayers to sanction a loan of $15,000.

Winnipeg, Man.—R. Mackenzie, secretary of the Canadian Council of Agriculture, announced a few days ago that the Grain Growers' Grain Co. planned this year to build a lumber mill, costing practically $150,000, upon a timber limit sixty miles east of Fort George, B.C., on the G. T. P.

CATALOGUES

Carbon Tool Steels.—Bulletin isssued by the Vanadium-Alloys Steel Co., Pittsburgh, Pa., dealing with the various grades of "Vasco" carbon tool steel. Each grade is described briefly stating the class of work for which it is best suited. The bulletin gives a set of rules for the proper hardening of water hardening steels. A list of extras is also included.

The Britannia Foundry Co., Coventry, England, have issued a series of leaflets dealing with an interesting line of foundry equipment, including the "Britannia" and "Coventry" molding machines, the "Git" spruce cutter, sand mixers and drying stoves. Each machine is illustrated and described, while a specification is also included, giving the principal dimensions and other data.

Whiting Cranes.—Of all types and for every service are described and illustrated in catalogue 127 recently issued by the Whiting Foundry Equipment Co., Harvey, Ill. The opening pages of the catalogue deal with electric traveling cranes illustrating and describing the latest features in Whiting crane construction. Following are brief descriptions of hand power, locomotive and cranes accompanied by illustrations showing the various types. The second half of the catalogue shows several typical illustrations of whiting cranes of various sizes and capacities in different classes of service. These views represent a wide field of service covered and are shown with the object of assisting purchasers to select the proper types.

BOOK REVIEW

Handbook for Machine Designers, Shop Men and Draftsmen, by Frederick A. Halsey, B.M.E.; 561 pages; 11 x 8 in. Published by McGraw-Hill Book Co., New York. Second edition, price $5.00 nett. The first edition of this volume appeared in 1913, being primarily an effort to rescue from the oblivion of the out of print, such contributions as are of direct use in the design of machinery. The standing of the author, as Editor Emeritus of the American Machinist was suffieient to guarantee the fulfilment of this original intention. As indicated, the book is a galaxy of selected contributions to the journal mentioned, and has been made up with a view to dropping old and introducing new material anywhere. In the short interval of three years, much matter has accumulated calling for an extensive revision· much of the matter now published is not readily accessible and some of it not in existence elsewhere. The subjets covered include shop and drawing office material which overlap to such an extent that the title was extended to include shopmen. The volume fulfils all of the requirements of a reference book, has all the conveniences of a pocket book, and possesses all the merits pertaining to original contributions by reputable authorities.

Forging 4.5 ins., 60 pdr., and 6 ins. Howitzer Shell

Staff Article

Shell-making in Canada has become quite commonplace, so to speak, yet, whether in the spheres of plant installation and equipment, or those of the operation methods and devices employed, it may be said that a mass of data awaits appropriation, an intimacy with which is no less desirable in the manufacture of metal-working plant specialties generally than in that directly and necessary to a variety type production of munitions.

ABOUT eighteen months ago when orders for larger shells came to Canada, the output of the then existing forging plants was not sufficient to meet the rapidly increasing demand for their product. Machine shops were multiplying in number, but their operations were somewhat restricted owing to the fact that they could not obtain a sufficient supply of forgings. The need of more forging plants to relieve the situation was therefore very real, but in a comparatively short space of time the situation was adjusted. The plant which is the subject of this article was established a few months after the period referred to above, and has done much to relieve the situation.

It is entirely a forging plant. The billets are shipped in already cut to the required length for forging, after which operation they are distributed to the machine shops to be finished. Forging may be termed an intermediate stage, and is incidentally a very important one. What might appear to the casual observer to be a simple operation, really requires a great deal of care, not only in the construction of the punches and dies, but in the actual forging and heating operations. A forging plant is a costly proposition to install. The presses are powerful machines and require a considerable capacity of pumping equipment to produce the necessary power to operate them.

FILLING FURNACE WITH 60-PDR. BILLETS. NOTE OVERHEAD RUNWAYS.

ROW OF BATCH FURNACES SHOWING SUSPENDED TONGS USED FOR HANDLING BILLETS.

At this particular plant there are eight Southwark hydraulic presses ranging from 210 tons to 500 tons capacity. The presses are installed in a row lengthways in the shop, with a row of furnaces on either side. This arrangement permits of the billets being lifted direct from the furnace to the press with neither lost time or motion, and obviates any appreciable loss of heat. To facilitate handling of the billets, overhead runways are installed along the front of both rows of furnaces with a turn-out leading from each furnace to the press that it is serving. The billets are carried by means of long tongs suspended about the middle by a chain from a carrier on the runway.

Furnace Installation

The furnaces were installed by the Southwark Foundry & Machine Co. Philadelphia. There are thirty-two batch furnaces and one continuous furnace, the latter being used only for heating the billets for the 6-in. shell forgings. The batch furnaces are used in conjunction with the presses making forgings for the 4.5-in. and 60 pdr. shell. A large number of furnaces are required so that the presses may be kept in operation continuously and not held up waiting for billets. The furnaces are drawn in rotation, that is, while one batch of billets is being drawn from the furnace the other batches are gradually coming up to the required heat. Eight furnaces to each of four presses for the piercing operations are required, making the total of thirty-two batch furnaces.

500-TON, 6-INCH SHELL FORGING PRESS WITH GRAVITY CARRIER IN FRONT.

The continuous furnace is one of the latest type. It is continuous as opposed to the batch type of furnace. The billets are fed into the furnace at the rear, from the billet pile in the yard. The billets roll through the furnace gradually and are drawn from the front as required. The billets are lifted from the furnace to the press by means of tongs in the same way as the smaller billets. The furnaces are all oil-fired, and are maintained at a temperature around 2,200 degrees Fah. The fuel oil is pumped by means of centrifugal pump from an underground tank in the yard to the furnaces. The air pressure for the oil burners is supplied by a Roots rotary blower, having a capacity of 13,000 cub. ft. per minute, and operated by Canadian Westinghouse motor. The blower and pump are located in a room adjoining the pumping plant.

4.5 in. Shell Forgings

The billet for the 4.5-in. shell is 4.8 ins. diameter, 10 ins. long, and weighs 52 pounds. The forging is of the same diameter and has a length of not less than 13 inches. The billet is heated in the furnace for about one hour. Immediately after being taken from the furnace, the scale is removed and the billet carried by tongs to the press. The removal of the scale is important, otherwise the dies might be damaged, and it might also prevent the steel from drawing uniformly when the punch is being forced into the metal. The billet is then dropped into the die and a centering ring placed on the upper end of die to guide the punch. The punch then descends producing a forging in one operation.

No drawing, properly speaking, is done on this forging, as the piercing causes an upward extension of metal out of the die. The return stroke of the press withdraws the punch and also forces the forging up from the die; the punch is then cooled by means of running water, and all scale is removed from the die box. Two presses are working on 4.5-inch shell forgings at this plant. All punches and dies are made of vanadium steel.

60 Pdr. Forgings

The forging of billets for 60 pdr. shell involves two operations, piercing and drawing. There are two sets of presses, making four altogether; two for the piercing operation being 350 ton presses and two for drawing being 210 ton units. The billet for the 60-pdr. forging is 5.45 ins. in diameter by 13 13/16 ins. long, and weighs 86 pounds. The forging is also 5.45 ins. in diameter, but the minimum length is 18 inches. The first or piercing operation is practically identical with that described above for the 4.5-in. forging. The billet after being pierced is put in the furnace for a short time to bring it up to forging heat again. It is then scaled and lifted over to the drawing press.

In the drawing operation, the punch is brought down so that its point exerts a certain pressure on the bottom or pocket of the forging which is supported on a die plate held over the opening of the main die. After the pocket is formed, the punch is drawn up a short distance to allow the die plate to be withdrawn, when the punch is forced downwards through the main die, the tapering bore of which reduces the outside of forging to the required size. The forging falls through to the ground and is then removed away to be cooled. The forgings are piled up in batches and cooled slowly to minimize the possibility of hardening.

6-in. Shell Forgings

The billets for 6-in. shells are forged in two 500-ton presses. Only one operation is necessary, that of piercing, so both presses are engaged in the same work. The billet is 6.4 in. in diameter by 17 ins. long, and weighs 158 pounds. The forging is of the same diameter, but has a minimum length of 23 inches. The piercing is done on the 6-in. forging in the same manner as far the other shells described above. The continuous furnace already referred to is used in connection with these two presses. The

TWO 500-TON PRESSES FORGING 6 INS. SHELL. CONTINUOUS FURNACE IN REAR, AND GRAVITY CARRIERS ALONGSIDE EACH PRESS.

6-in. forgings are considerably heavier than the 60-pdr., and so to facilitate handling, a system of gravity carriers has been installed.

In the illustration will be seen the carrier by which the hot forgings after being pierced roll down from the press to the ground. Another system of gravity carriers picks up the forgings near the press and carries them to the other end of the shop to the cooling piles. The carrier systems were supplied by the Canadian Matthews Gravity Carrier Co., Toronto. They save both time and labor, and assist in the generally efficient operation of the plant. All the forgings of each size have the billet number stamped on the base.

FURNACES USED FOR ANNEALING FORGINGS THAT REQUIRE HEAT TREATMENT.

Hydraulic Plant for Presses

The hydraulic plant for operating the presses consists of two large accumulators and five motor-driven pumps. The pumps are horizontal, direct-acting units, and were built by the Deane Steam Pump Co., Holyoake, Mass. Three of these pumps have a capacity of 250 gallons per minute, each being driven by a 250-h.p. Canadian Westinghouse motor. Another pump has a capacity of 200 gallons per minute, and is driven by a 200-h.p. Canadian Westinghouse motor, while the fifth pump is a 150 gallons per minute unit, and is driven by a 150-h.p. Canadian Westinghouse motor. The motors are all A.C. machines using Hydro current.

SEASONING OF CASTINGS*

By Richard Moldenke.**

ONE of the little-known characteristics of cast iron, which nevertheless has an important bearing on results where accuracy in machining is essential, is the ability of this material to ease up internal strains when allowed to remain quiescent for a more or less extended period of time. It seems as if the molecules in such a casting, by virtue of their mobility, can adjust their relative positions to an extent sufficient to overcome some of the existing stresses.

The following instance will perhaps give a fair idea of the condition a casting may be in when just shaken out of the sand: A very large sheave-wheel. after shaking out, was taken outdoors to be cleaned and made ready for turning up. It was leaned against the side of the building, but before much could be done an arm tore apart with a loud report. Investigation showed that the sun had been shining on the upper rim, thus adding a slight strain to those already existing within the arm and thus overbalancing the strength of the metal in tension. Had this sheave been kept under cover for a while, or at least until machined, the strains would have eased off sufficiently and allowed the sun to look upon it without disaster.

It will not be necessary to multiply examples. Every engineer knows the danger of water-hammer in pipe lines, particularly if the latter are of cast iron. Every mechanic knows, or should know, that it is not good to strike a fitting that is under steam pressure.

Shrinkage and Contraction—A Distinction

It will be necessary to write a few words about the internal strains in castings—the so-called casting strains we hear so much about. It is generally known that to get a casting reasonably true to the dimensions wanted requires a slightly larger pattern. The usual allowance for grey iron is 1/8 inch to the foot, and 1/4 inch to the foot for white iron. This reduction in length, breadth and thickness in a casting is erroneously called shrinkage. It should be called contraction, as for practical purposes it is simply the difference in dimensions of the casting red-hot and cold. In fact, it is really a volumnar contraction, and takes place after the metal has set.

The real shrinkage covers an entirely different situation. When a casting is poorly designed, it is impossible to feed the mold properly when pouring. The thinner sections set more quickly than the thick ones and may leave the latter without means of drawing in liquid metal to compensate for the reduction in volume in the act of setting. As the metal sets against the mold walls first, and gradually thickens from the surface inward, when the influx of fresh supplies is stopped there results a void in the centre, or at least a spongy portion. This is shrinkage, and can be seen more particularly in white iron, by reason of its greater reduction in volume from liquid to solid form, apart from the final contraction from red heat to ordinary temperatures. Such shrinkage usually takes place at abrupt angles, in thick parts adjoining thin ones, in the rims of flywheels, hubs of pulleys, at the flanges of cylinders, etc.

Dual Volume Reduction

It will be seen from the above that there are really two kinds of reduction in volume to be reckoned with: First, that due to the change from the liquid to the solid state; second, the reduction in volume after setting until ordinary temperatures have been reached. The first, often called interior shrinkage, is a rather serious occurrence. The specific gravity of molten iron is about 6.65: it does not vary widely from this figure whether the metal on setting is grey or white in fracture—all the carbon being combined when in the molten state. On setting, however, if grey iron results, the specific gravity will be over 6.8, and if white iron, up to 7.8. The formation of graphite in the structure accounts for the comparatively moderate increase in the case of grey iron. In average cast iron with 7.3 specific gravity, the increase in density is 0.65, or 9 per cent., which means a very big decrease in volume for equal weights of molten and solid metal. This situation accounts for the quantities of molten metal that have to be added to a mold after pouring it full in the first place, and in the case of small castings, particularly when of white iron, for the funnel-shaped sprue left in the pouring basis or gate.

Contrast this with the eventual reduction in volume after setting. Here we have a linear reduction of about 1 per cent. in every direction, which is an infinitesimal amount when compared with the real metal shrinkage.

It stands to reason, that, if the metal in setting has the power to pull apart, whatever liquid material may remain after feeding has stopped, thus causing large spongy parts in the interior of a casting; powerful strains which affect the strength injuriously must have occurred. This is apart from the reduction of strength in the material for the section itself. In other words, not only will the metal have a lower tensile strength because of the spongy nature

*From a paper presented at the American Institute of Mining Engineers, New York, Feb., 1917.

**Consulting Metallurgist, Watchung, N.J.

of part of the section, but the interior strains counterbalance part of the tensile strength that is available.

This situation is intensified by the fact that the metal in setting does so far more quickly at the mold surface than in the interior—the cold sand walls drawing away the heat from the molten iron more quickly at the beginning of the setting process than later when this heat has to travel through a more or less thick shell of metal already set. The consequence is a higher percentage of combined carbon at the surface than in the interior of the casting. In chilling the surface, we have a white iron surface and a grey iron interior. The relative change in the specific gravities of the same molten iron turned into two extreme forms of iron as cast will indicate what strains there must be within the casting due to the differences in volume which the two metals want to occupy when set, but cannot properly occupy on account of the quickness of the setting action.

Contraction of Set Metal

Finally come the strains due to the contraction in the set material until ordinary temperatures have been reached. This has been stated as ⅛ inch to the foot in grey iron and ¼ inch to the foot in white iron. In large castings this is very serious. Suppose, in the case of a big flywheel, the rim sets fast enough to hold the much cooler arm as in one set of jaws of a testing machine, the hub, held by the arms on the other side of the wheel, being the other set of jaws. Surely the arm in wanting to reduce in length ⅛ inch to the foot must be under a terrific strain if not allowed to do so. In the case of white iron the situation is much worse. Such castings as handbrake wheels (subsequently annealed for malleable castings), snap apart when allowed to cool in the sand in the ordinary way. Work of this kind must be shaken out as quickly as set, taken to special ovens and allowed to cool down very gradually.

Overcoming Injurious Strains

Sufficient has been said to make the case of cast iron look very weak. Fortunately, there are two phenomena which help to overcome some of the injurious strains set up. The first is the fact that cast iron in the act of setting (between liquid and solid), can be stretched. The second is the seasoning or easing up of the remaining strains after the final contraction through the mobility of the molecules. It is the stretching of grey iron during the set ting that saves the flywheel arm from rupture before the new strains due to final contraction are introduced. It is the inability of white iron to stretch very much, which causes so many cracked castings in the malleable process which would not be seriously affected by the final contraction.

Castings Test

This discussion of the actual situation in making castings has another bearing. Purchasers of castings may wonder why foundry men who really know something about their basic material are so uncompromisingly opposed to test coupons on their product. The man who is at least somewhat familiar with cast iron should realize that it is unfair to the maker of the casting to judge its value by a test piece subject to a variety of strains introduced as the result of position, manner of attachment, method of pouring of the metal, etc. It is further unfair to the purchaser to judge by coupons, as there are many ways of artificially strengthening such test pieces There is only one way of testing a casting properly, and that is to break it. Obviously this will not do, and hence for repetition work a given percentage of castings can be thus tested. For all other cases the only method of obtaining reasonable assurance on the subject is to make standard test bars, entirely apart from the castings, but of the same iron. These test bars should be made under conditions giving the iron the best possible chance to show just what it is. neither artificially strengthened, nor filled with strains and thus deliberately weakened.

Every mechanic knows that, in planing up a slab of cast iron on both sides to get a true job, it is necessary to take a light cut, reverse, and take a cut on the other side, then reverse again for the finishing cut, finally reversing for the last cut. If this is not done, there will be warped surfaces to deal with on account of the internal strains. Again, it is well known that a true piston is rather difficult to produce. Even after grinding to a finish, it is apt to get out of true. It is not so generally known, however, that if such a cast iron plate or piston is allowed to remain in storage for a long period, the results will be much more satisfactory. The castings have seasoned. Where establishments are familiar with future production demands, orders for castings are placed far ahead of requirements. Since, however, on getting to the bottom of a big pile the difficulty of tracing defective work becomes correspondingly harder, only shops having their own foundries are likely to do much storing.

The present demand for very high-class machined castings, as evinced by automobile cylinders, pistons, engine and compressor cylinders, etc., should bring this question of seasoning out very prominently. Inquiry by the writer has shown but little knowledge on the subject in the trade generally, though first-class foundrymen were very much alive to the matter. In general, the difficulty seems to be the inability of storing up ahead, or, if this is done, or discovering defective product when least expected.

Increasing Strength by Tumbling

We are indebted to the well-known metallurgist, A. E. Outerbridge, Jr., for what seems to be the best indirect explanation of seasoning. In his famous experiments on tumbling castings to increase their strength, he found that by the action of light blows, often repeated, the internal strains were relieved to such an extent that the real value of the metal came into play. The mobility of the molecules was aided by artificial means. Incidentally, however, the tests establish the mobility of the molecules in cast iron very satisfactorily. Replace half-an-hour's tumbling by six months' quiescence and the molecules will have done their work with somewhat the same results.

In view of the possible depression scheduled for us on the close of hostilities in Europe, would it not be well to ease up operations slowly instead of shutting down tight? This would help the industrial situation adjust itself more safely and at the same time permit supplies of castings to accumulate, which will be all the better for having seasoned.

BRITISH MUNITION PLANTS AFTER THE WAR

IN discussing the possible uses after the war for the additional plants and machinery that have been created for the production of munitions in Great Britain, the London *Times* calls attention to their enormous importance as a national asset and to the thought which their destiny has stimulated in the engineering trades. It further states:

"Perhaps the most pregnant of the many suggestions are those which contemplate these factories as the new homes of old and smaller works. Among the respects in which British manufacturers have been at a disadvantage compared with their competitors in the United States is the nature of their premises. The old establishment that has given them experience and connection has also given them old premises, round which have grown up houses which now are themselves old, and are often placed in neighborhoods which are as little suited to the best deelopment of vthe workers and their families as the old works and some of the old prejudices are to the efficiency of the business. To move these works from the slums in which many of them are placed into neighborhoods with light and air and grass, and to transfer their machinery from shops that have grown up without plan into premises designed for efficient handling and 'routing' would be to give the workers and the enterprise a fresh lease of life.

"Some point out that the design of these new works is particularly adapted to subdivision and suggest that their utility would be all the wider and more general if they were divided into separate occupations and used by firms of whom each could specialize in the quantity production of individual parts, and one or more in the assembling of them. This method has been used largely and successfully by American manufacturers, sometimes further apart from each other than these works would be. The advance which has been made for war manufacturers in the use of limit gages and the production of interchangeable parts has placed British engineering in an entirely new position for adopting this method of manufacture generally."

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

MILLING SLOTS IN SHELL NOSES

By R. Hamilton.

AMONG the changes effected in the 4.5 Mark VII., high explosive shell, is that of three small slots to be cut in the nose, at an angle of 30 degrees with the face. The purpose of these slots is to lock the fuse in a permanent position, after it has been firmly screwed in, by burring the metal of the fuse down into these three slots. While the operation of cutting these three slots is comparatively simple, the time required to perform the work and the method of holding the shell while doing so is an important factor in the rapid accomplishment of such an apparently little detail. Various methods have been adopted for holding the work, some of these being more or less complicated, but the two sketches herewith illustrate devices both simple in design and efficient in operation. They were developed by the Imperial Munitions Board from suggestions submitted by Williams & Wilson, Montreal. Both fixtures are made for milling machine use; Fig. 1 to be moved horizontally below the cutter, and Fig. 2 to be operated vertically at one side of the cutter. The body casting is made so that the bore will come at an angle of 30 degrees with the vertical, a recess being provided to assure a clean cut being taken for the fit of the shell chuck B, this piece having a collar cast integral with the main portion, so that the shell can be revolved freely. A small hole D is drilled in the base to allow the free escape of air when the shells are being placed in position. Three equidistant holes are drilled near the base, so that the chuck can be locked in the desired position when slots are being milled. The locking bolt E is operated by the spring shown, and released by the knurled button F.

The design of the fixture shown in Fig. 2 is somewhat different, but in this case the table of the machine is operated in a vertical direction to mill the slots. The body casting in this instance is made so that the axis of the shell is kept at an angle of 30 degrees with the horizontal. To the base of the fixture A, two small steel pieces are secured to retain the jig in a central position with the milling machine table. The shell retaining piece C, which revolves in the main casting, has a quick-acting clamping device, as shown at D, thus preventing the shell from turning while the cuts are being made. The handle E provides an easy means of turning the shell to the three desired positions; these being determined by the locating bolt F, operated by the spring G acting against the shoulder H. This portion is so designed that it is self-releasing, the bolt springing into position when the slot comes in line; the bolt operating in a dovetail slot cast integral with the main casting. Lateral play is eliminated by the short sectional collar I. The block J gauges the location of the shell in the chuck.

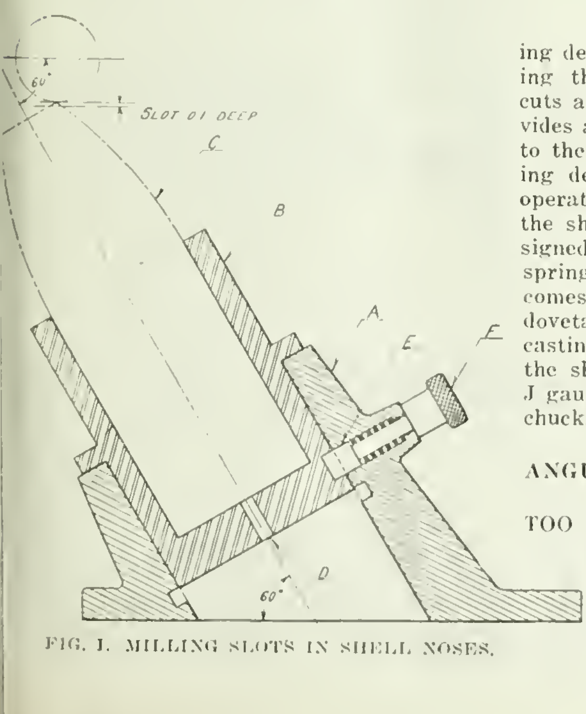

FIG. 1. MILLING SLOTS IN SHELL NOSES.

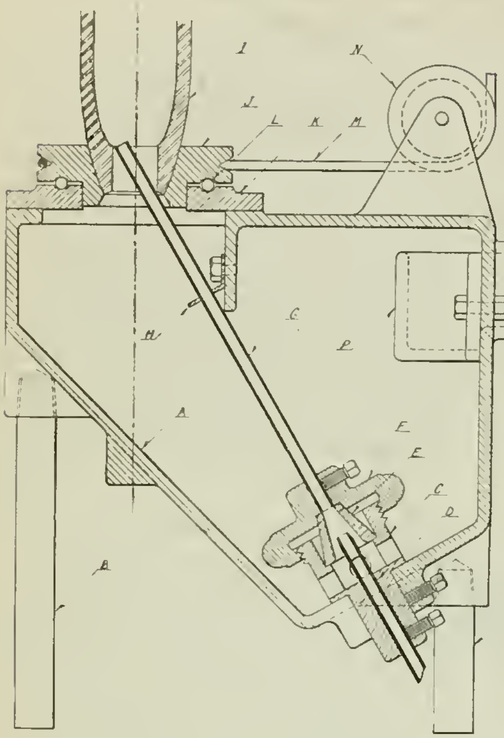
ANGULAR SHELL GRIT CLEANER

By J. H. R.

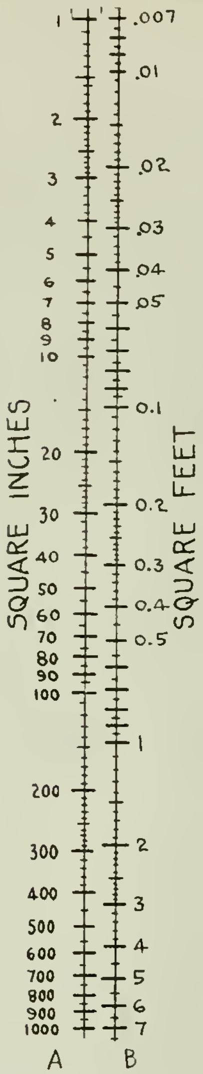
TOO much emphasis cannot be laid on the necessity of thoroughly cleaning the interior of the shells after the nosing operation and subsequent machining. It is essential that this operation be carefully performed in order that the surface of the inside walls will be in a condition to receive and retain the coating of varnish with which all shells are prepared. The method of applying the cleaning medium is one that should receive a great deal of attention, and a careful study of the various requirements is a very important factor in the securing of satisfactory results. The general practice has been to force the sand or grit into the shell without considering the work that is to be accomplished. When the sand is blown directly into the shell in a vertical direction, the base receives the full force of the blast, and the cleaning of the walls and the profile just inside the nose can only be accomplished by the action of the sand as it falls back and out of the shell. Owing to the condition of that portion of the shell immediately below the nose thread, caused by the hot nosing process, a scaley surface is unavoidably formed, and where machining is not resorted to, it is highly desirable to thoroughly clean this section before the varnish is applied. Even when this profile is machined, it is well to have the sand come in contact with the surface so that all grit or scale will be removed. After much experimenting with various forms of sand-blasting appliances, the Jenckes Machine Co., Sherbrooke Que., designed the cleaner illustrated in the accompanying sketch.

The construction of this device is such that the sand is blown directly against that section of the shell that most requires it. Owing to the velocity at which the sand is forced into the shell, it is practically impossible to have any bends in the nozzle pipe, as the friction would be so great that the life of the nozzle would be very short. For this reason it



ANGULAR SHELL GRIT CLEANER.

is deemed very advisable to have the sand forced through in a direct line. As it is also obvious that the entire circumference be subjected to the action of the blast, the shell is placed in a vertical position and revolved during the cleaning operation. As shown in the sketch, the bowl or container A is mounted in such a position that the upper surface lies in a horizontal plane, legs B being of suitable length to attain this ideal. Secured to the lower section of the container is the connecting piece C, through which the air pipe D passes; being firmly secured by the set screws shown. The cone-shaped injector piece E is held in position by the nut F. The delivery pipe G which carries the air and sand to the work is firmly held in the nut F, the lower end resting on the cone E, while the upper end is supported by means of the band iron clamp H. The shell I is held in a vertical position, the nose resting in the piece J, riding on ball bearings on the roller plate K. The rotating flange, together with the shell, is operated by the small ¾-inch round belt M, passing over the idler N, and up to an overhead shaft. While the sectional view of this device only shows one shell being operated on, the cleaner now in use is of the twin type, so that two shells can be operated on at the same time. The sand enters the bowl or container through the opening O, being deflected by means of the box P. When the air is turned on, the force of the blast draws the sand in through the openings in the piece C, and forces it along with the air through the cone E, and then up the delivery pipe G to the interior of the shell. The action of this device is highly satisfactory, the angular direction of the blast proving a very efficient method of cleaning the inside profile of the nose.



CONVERTING SQ. INCHES INTO SQ. FEET

By N. G. Near

ENGINEERS will find this scale handy for quickly converting square inches into square feet, or vice versa. Simply glance across from one column to the other and the answer is immediately found. For example:—How many square feet are there in 300 sq. inches? Find the 300 in volumn A and glance across to column B. The answer is—practically 2.1 sq. ft. Again, how many square inches are there in 2 sq. ft.? Find the 2 in column B and glance across to column A. The answer is, of course, 288, but we would call it roughly 290.

The first operation is the one that is most difficult to perform "longhand." Multiplying generally comes more easily, and so the second operation would perhaps be used more often.

MACHINING PISTON ROD FORGINGS ON HEXAGON TURRET LATHE

Herbert's Monthly.

THE hexagon turret lathe is principally intended to be used for making articles direct from the bar, the great savings in labor costs which can be effected by its use resulting from the speed with which the work can be turned out and the elimination of the expensive process of forging. The possibilities of the machine on bar work are now generally recognized, but it is not always realized that it may also be used to great advantage for dealing with many articles which, owing to their shape, must be made from forgings.

In Fig. 1 is shown a combined piston rod and crosshead for a steam winch. This article must obviously be made from a forging, and might, if made in large quantities, be looked upon as a job for a combination turret lathe; if only a small number could be put in hand at one time, it would probably be finished in an ordinary centre lathe. The hexagon turret lathe is, however, the proper machine to use for this work; it is better than the combination turret lathe, because only one or two special tools, in addition to the standard equipment, are required, whilst the time taken to complete the piece (30 minutes) is about one-fourth of that which would be necessary if the work were done on the ordinary lathe. Particulars of the tool layout are from the plant of John Lynn & Co., Sunderland, England, who are regularly finishing these piston rods on a hexagon turret lathe, and it will be noted that they demonstrate in a convincing manner the flexibility of the machine; similar adaptations will doubtless occur to other users.

At preliminary operations the two sides of the crossheads, the slot and the end, are machined symmetrical with the rough piston rod, so that when chucked in the fixture it will run true. The method of chucking and the tool layout are shown in Fig. 2, the tools being numbered in the order in which they are used so as to illustrate the sequence of operations. The work is held on a special fixture bolted to the spindle flange,

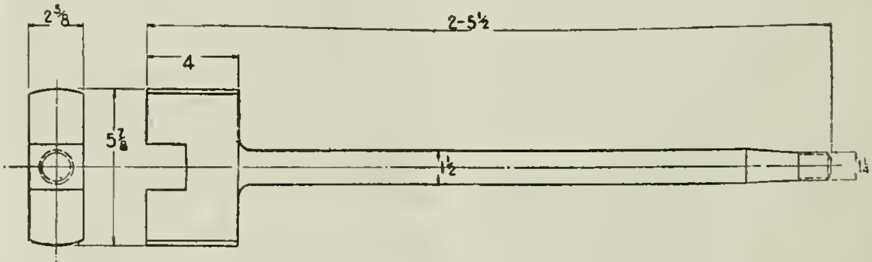


FIG. 1.

the design being such that the draw-in chuck does not need to be removed. The fixture itself is of mild steel, turned circular, and then milled away to form an angle plate. The work is located from the previously machined slot by a square-headed stud driven into the centre of the fixture, and is clamped by a nut, stud and clamp plate.

1—This is a standard ⅜-in. taper shank twist drill, which drills a little way up the end of the work so as to provide a support for the starting tool (2). The drill is held in a taper socket in the turret hole, the end being supported by a cast iron bush fitting in the triple toolholder.

2—This is a starting tool which trues up the end of the forging so as to give the roller steady turner a true start. It is provided with a revolving steady peg fitting in the ⅜ in. hole.

3—This is a standard roller steady turner, which turns the 1½ in. diameter at one cut.

4—This is another roller steady turner, which turns the thread diameter. In this case the rollers are running on the 1½ in diameter, and the tool is cranked so that the cutting edge is behind the rollers. In this way concentricity between the two diameters is assured.

5—This is a knee-turning tool-holder for turning the large diameter. It is provided with a supporting bush fitting on the 1½ in. diameter.

6—This is a special forming slide operated through a worm and worm wheel, which carries two tools. The first tool is used for facing the shoulder, and is carried on the back of the slide. The standard cut-off slide, being lever-operated, is unsuitable for this facing operation, as the cut is an intermittent one. Two bushes are provided in the turret hole for use with this slide, and are interchanged, this being done without difficulty in the relieved turret holes. The first bush fits the 1½ in. diameter whilst facing is taking place; the second one fits the thread diameter, and is used whilst forming the taper with the tool on the front of the slide.

7—This illustrates a standard roller steady ending tool, which rounds the end of the work.

8—This shows Coventry self-opening die-head for screwing.

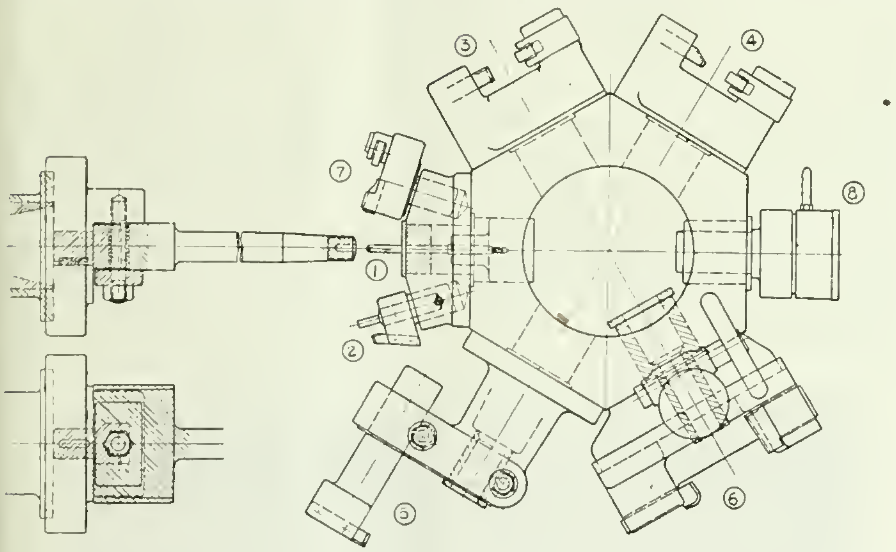

FIG. 2.

COPPER IN STEEL

By Dale Street

FOR more than two generations the presence of copper in steel has been considered in many quarters to have a wholly deleterious effect, and one may still come across steel specifications in which copper is barred. Yet it has been long ago proved that copper in steel, instead of being an evil, is quite harmless, and is sometimes distinctly beneficial. The evidence is overwhelming that small quantities of copper, say, about 0.5 per cent., have little or no material influence on mechanical properties. It is still held by some that copper tends to make steel red-short, but many authorities who have made reliable trials have found it to have no such effect. Arnold, Stead and Evans found that the presence of 0.1 per cent. of copper in steel had only the most trifling effect in its qualities, and that such effect as it has is in its favor. It raises the yield point and tensile strength, and has little effect on the ductility. Some of the finest tool steel ever made contained 0.2 per cent. copper. It has been proved by Dr. Stead and others that even small quantities of copper in steel make it more resistant to acid corrosion, and D. M. Buck has shown that copper in steel preserves them from general corrosion. Dr. Stead attacks the prevalent prejudice against copper with characteristic vigor, and protests that it is time it was abandoned, if only for the reason that it has prevented the importation into Britain of cupreous iron ores, which are really excellent for steelmaking.

TEMPERATURES FOR CARBON STEELS

By Mark Meredith.

THE question of the temperatures to which pure carbon steels should be heated for the several purposes of (a) obtaining a fine structure, (b) hardening, (c) securing the best mechanical properties, and (d) hardening with a view of subsequent tempering, is one of great interest in connection with the influence of elements on the mechanical properties of steel. Sauveur gave 800 deg. C. as the temperature suitable for hardening, tempering, and annealing steels containing between 0.9 and 1.5 per cent. of carbon; but Dr. Stead remarks that in hardening razors and fine-cutting tools it is not usual to heat the steel above 760 deg. C. As a matter of fact, 735 deg. to 740 deg. is the theoretical point to which they should be heated, but in practice it is found safer to exceed this, as it is impossible for the artisan to obtain the exact temperature, and he might sometimes have the heat below the critical point, and so produce soft instead of hardened steel, on quenching in water. Dr. Stead confirms Professor Arnold's contention that there is a range of only 2 or 3 deg. between the temperature at which the steel, on the one hand, becomes intensely hard on quenching, and that at which, on the other, it is quite soft.

Whilst there is little harm in going somewhat above the theoretically correct temperature, that process must not be carried too far. Carbon tool steels, if heated to 900 deg. or 1,000 deg., and quenched from these temperatures, would be useless for cutting purposes, and would have a glaring coarse fracture when broken, and be exceedingly fragile. Subsequent tempering, however, modifies the condition. Brinell and others have found that steels with from 0.6 to 1 per cent. carbon give good mechanical results, if hardened at a temperature of 1,000 deg., and afterwards tempered at 550 deg. C., compared with steels normalized at much higher temperatures, and which have a coarser structure. It would appear, therefore, that temperatures suitable for hardening and refining are lower than those which should be used for normalizing and for hardening and tempering. Dr. Stead puts these conclusions into graphic form by super-imposing upon Sauveur's original curve of oil hardening and tempering temperatures two further curves, one indicating the temperatures to which theoretically pure carbon steels should be heated to obtain the finest structure and for hardening tools, and the other the temperatures which should be used when heating for oil hardening and tempering to get the best mechanical properties.

Censor Humor.—A soldier writing home to his people described how he had been buried alive for a couple of hours in a demolished dugout, but was eventually extricated by his comrades. He added by way of consolation—"I had the satisfaction of sending five of the Germans to hell." The Censor in passing the letter had drawn a line through the sentence, but wrote underneath—"It is not permitted to refer to the whereabouts of the enemy."

PROCESSES IN MANUFACTURE

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

HEAT TREATMENT OF LARGE FORGINGS

By Sir William Beardmore, Bart.

IN the heat treatment of large forgings, there are no metallurgical principles involved which do not apply with equal force to the heat treatment of small forgings, such differences as exist being entirely due to the limitations which large forgings impose on the practical conditions under which the heat treatment is carried out. For every class of forging, it is desired that the material from which it is made should give the mechanical tests required by a suitable choice of composition, but, in addition, it is most necessary that the material be in such a physical condition that brittleness and chance of sudden failure be reduced to a minimum.

In carbon-steel forgings produced to meet a definite mechanical test specification, this is equivalent to saying that the steel must possess the least crystalline growth or the smallest grain size, and the object of all heat treatment is to confer this condition on the forging before it leaves the steel works. It is well known that, at any chosen temperature, the time the material is kept at its heat and the time taken to cool down to normal temperature again have an all-important influence on the grain size, and it is for this reason that in large forgings all the difficulties of heat treatment are magnified; and, in the author's opinion, a limit is ultimately reached in the size of the forging beyond which a plain carbon-steel cannot be used with safety, and the use of an alloy steel becomes imperative.

The slowness with which heavy masses of steel cool down results in large crystal grains at the centre of the mass, and, to avoid this, recourse has to be made to oil-quenching to hasten the cooling down, and so to diminish the size of the grain, while a subsequent reheating is generally necessary to remove the hardness introduced by the quenching operation. With small forgings, a simple annealing will put the material into the condition which will give satisfactory and safe results, but for large forgings some form of heat treatment is very necessary to get the best results.

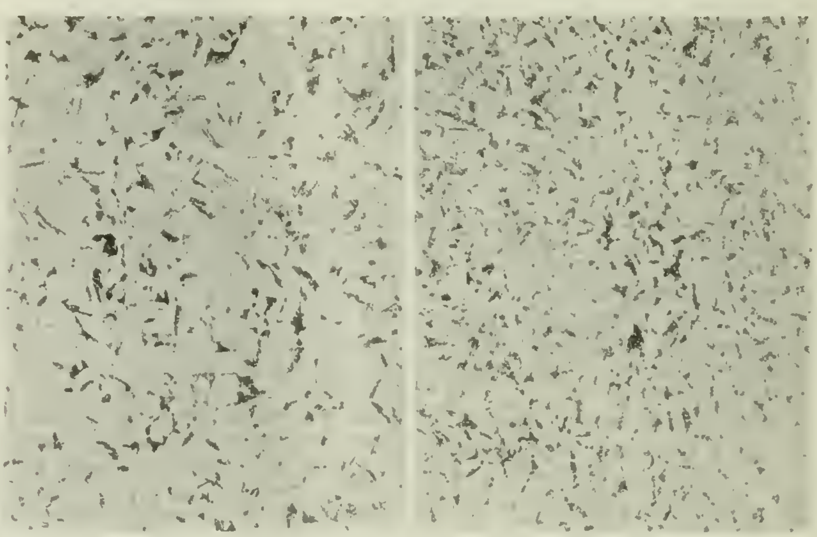
It is a fact which is not sufficiently realized by engineers that, in plain carbon-steel, the effect of oil-quenching is not uniform over the cross-section, but diminishes the farther one goes from the outside surface. With very large forgings, therefore, a stage is reached at which, owing to the size of the forging, the quenching effect at the centre is so small that it is insufficient to confer any benefit on the material, and it becomes impossible to guarantee the uniform results which are wanted. That this effect is a real one can be seen from the accompanying photomicrographs of a large oil-treated shaft and from the tests taken. This shaft is 18 inches diameter, and of the following per centage composition:—

C.	Mn.	Si.	S.	P.
0.18	0.65	0.10	0.048	0.037

It was heated in 820° C. (1,505° F.), kept two hours and cooled in oil. Tests were taken from the outside skin and centre, and gave results as shown in the following table:—

	Elastic Limit Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation on 2 inches. Per cent.	Reduction of Area. Per cent.
Outside	17.5	33.1	27.0	53.1
Centre	15.0	29.0	31.0	46.0

The structures are given in photomicrographs, Figs. 1 and 2, being the outside and inside respectively. The tests taken from the centre of the shaft have a lower tonnage than those from the outside, due to the fact that the quenching is not so effective. Photomicrograph Fig. 2, confirms this. With a higher carbon steel it can be understood that the difference will be greater.



OIL HARDENED 18-INCH SHAFT MAGNIFIEE 100 DIAMETERS.
FIG. 1. OUTSIDE SKIN. FIG. 2. INSIDE.

The effect of work is very important, and there is an intimate relation under practical conditions between the grain condition of a forging and the amount of work which has been put on it during forging. For the very best results, the ration of the cross-section of the ingot and the largest cross-section of the forging should have a minimum value which it is advisable should not be less than three. Preferably it should be as great as possible, but it cannot always be adhered to, since for large sizes it is limited by the maximum size of ingot with which the presses can deal and sometimes by the shape of the forging itself. For an ingot 83 inches in diameter the maximum size of the forging should not exceed 48 inches for the best practice, and from a steel-maker's point of view, until the demand warrants the outlay of plant for dealing with still larger ingots, larger forgings than this should be built up rather than manufactured in one piece. In this connection the cause of commercial efficiency would be better served if engineers, in bringing out new designs in heavy steel construction, would consult the metallurgist and the steel manufacturer as to the best method of using their combined knowledge in the design and production of special requirements.

Though not strictly a forging, the following example illustrates very well what has been said above regarding the heat treatment of heavy forgings. The order specified steel discs 55 inches dia-

*From a paper presented before the Institution of Mechanical Engineers.

meter and 11 inches thick with a mechanical test of—

Yield-Point. Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation (on ratio $\frac{\text{length}}{\text{diameter}} = 10$) Per cent.
23	45	20

This was the best that could be obtained, and was below the specified tests.

They were required to revolve at a high speed, and for magnetic reasons it was necessary to use a carbon-steel. The ingots were forged and then rolled to size from material of the following composition:—

C.	Si.	Mn.	S.	P.
0.53/0.54	0.18	0.50	0.029	0.040

and were given a heat treatment after this operation, which consisted of—

(1)—Heating to 780° C. (1,436° F.) for 2 hours and cooling in oil.

(2)—Heating to 550° C. (1,022° F.) for 4 hours and cooling in air.

Tests were taken from the centre of the slab (midway between the two surfaces), and they gave the following results:—

—	Yield-Point. Tons per sq. inch.	Ultimate Stress. Tons per sq. inch.	Elongation (on ratio $\frac{\text{length}}{\text{diameter}} = 10$) Per cent.	Reduction of Area. Per cent.
Cross test	23.6	42.3	14.0	39.3

There were two reasons for this; the carbon was too low and the thickness of the slabs was too great to allow the oil-quenching taking sufficient effect to attain the high tonnage required. An-

higher carbon material giving—

C.	Si.	Mn.	S.	P.
0.62/0.63	0.25	0.70	0.023	0.024

other ingot was therefore cast, from a and it was forged and rolled to 5½ inches thick to the size given in Fig. 3

In this way it was sought to avoid any unsoundness that might exist down the centre line. At the same time the test specification was amended so that the elongation required was 22 per cent. on 2 inches instead of 20 on a ratio

$\frac{\text{length}}{\text{diameter}} = 10$. The plate was heat-treated as follows:—

(1)—Heated to 900° C. (1,652° F.), kept 1 hour and cooled in oil.

(2)—Heated to 760° C. (1,400° F.), kept 1 hour and cooled in oil.

(3)—Heated to 640° C. (1,184° F.), kept 8 hours and cooled in air,

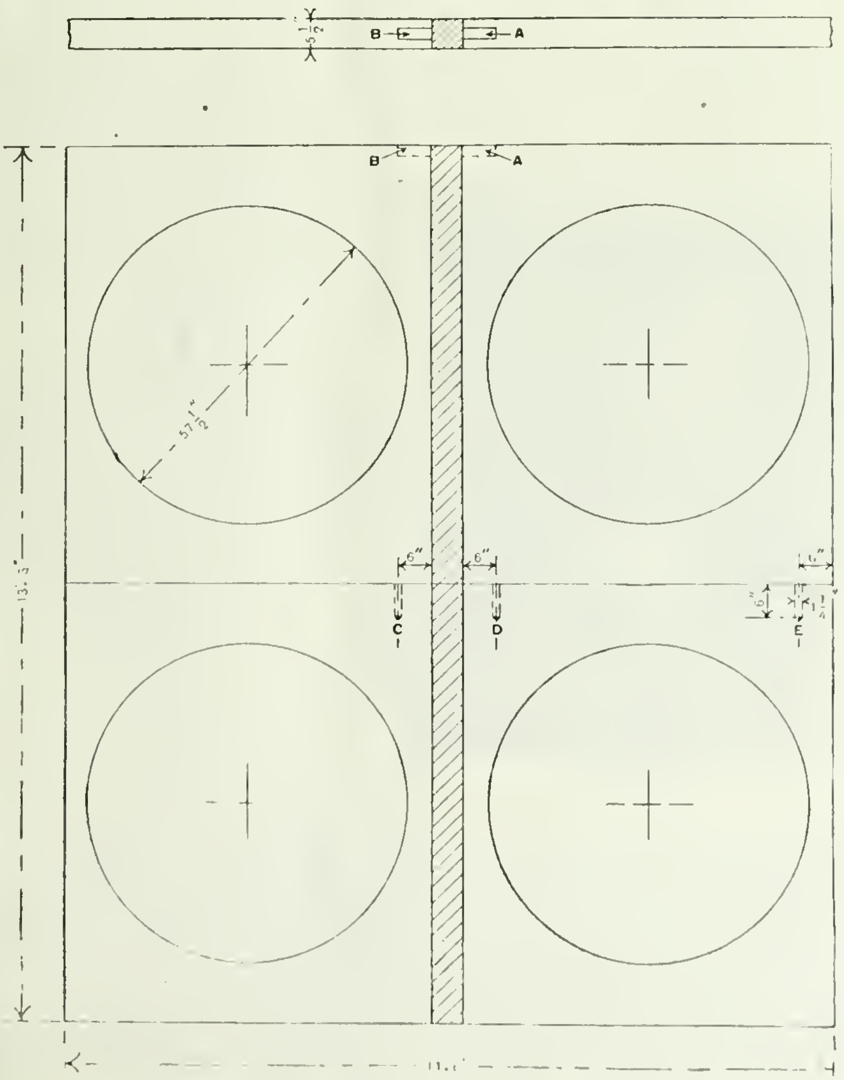


FIG. 3. FORGED AND ROLLED SLAB USED FOR TEST

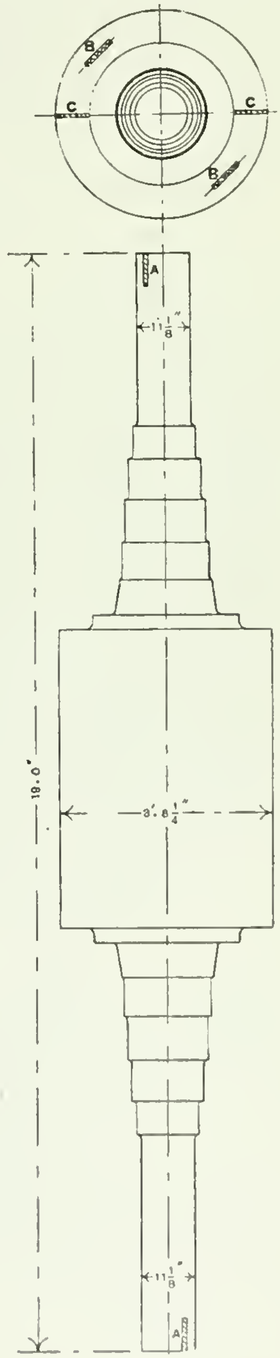

FIG. 1. LARGE ROTOR SPINDLE.

and the following tests refer to the corresponding letter in Fig. 3:—

Fig. 3.	Yield-Point. Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation on 2 ins. Per cent.	Reduction of Area. Per cent.	Fracture.
A	28.1	46.2	28.0	52.4	Silky fibrous.
B	27.9	46.0	27.0	44.4	(10% fibrous. (90% fine gran.
C	27.2	46.6	25.0	47.2	(40% fibrous. (60% fine gran.
D	26.4	46.0	26.0	42.0	(30% fibrous. (70% fine gran.
E	26.8	46.2	27.0	44.4	(50% fibrous. (50% fine gran.

These results are satisfactory according to the test specification, and show the improvement effected by slight changes in the method of manufacture. The improvement due to rolling to a smaller thickness alone was seen when first material containing 0.53 to 0.54 per cent. carbon was rolled down from 11 inches to 5½ inches, and then retreated in the same manner, for it gave the following tests:—

—	Yield-Point. Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation (ratio length 10). Per cent.	Remarks. Ins. thick.
Length	26.3	44.9	15.8	5½
Cross	25.7	44.2	16.5	5½
Cross	23.6	42.3	14.0	11

This result could have been still further improved by decreasing the thickness to 3 inches, but it shows how important the effect of work is on carbon-steels, and how it may make just that difference between success and failure.

For high-tensile material—that is, material over 40 tons strength—where the factor of safety is limited owing to the special conditions under which the material has to be employed, it will generally be safer to use an alloy steel, since for the same tonnage a very much tougher material can be developed; but, for material whose tensile strength is below this figure, there is not the same necessity, and excellent results can be obtained from oil-treated low-carbon steel.

Fig. 4 indicates the outline of a large rotor-spindle which was made to the following test specification:—

Yield-Point .... 20 tons per sq. in.
Ultimate Stress ......36 tons per sq. in.
Elongation on 2 ins. . .24 per cent.

It will be seen from the drawing that the largest diameter was 3 feet 8¼ ins., and the minimum diameter only 11¼ ins., so that if such an ingot were used as would give the requisite amount of work for the largest section, the amount of time and money spent in forging down this ingot to 11 inches would be out of all proportion; and so in this case, as in many other cases, the best metallurgical conditions are incompatible with the best commercial conditions, and a compromise has to be effected. An ingot 60 inches in diameter was used of the following composition:—

C.	Mn.	Si.	S.	P.
0.38	0.89	0.21	0.029	0.044

In the heat treatment of this job, and of jobs having similar shapes, when the forging is put into the furnace, the time taken to heat up the heavy centre section is much longer than the time taken to heat up the end sections. For instance, the end-pieces of 11 inches diameter could be heated up in about 4 hours, while the centre would take about 20 hours to reach the same heat, so that before the forging would be uniform the end-pieces would have been at their best for 16 hours, and would have grown such a crystalline grain in consequence that any good effect of the oil treatment would have been annulled. To avoid this, the ends were covered with asbestos sheets, leaving only the centre exposed when the forging was charged into the furnace, and this sheeting was removed after 15½ hours in the furnace, so that the forging attained its heat uniformly as a whole, and the crystal grain in consequence was uniform throughout.

The test results obtained were very good, and are given below. A refers to length tests taken, one from each end of forging, B to tests taken circumferentially from a ring taken from the centre part after treatment, and C to tests taken radially from the same ring. In both B and C tests two tests were taken from opposite diameters:—

Fig. 4.	Yield-Point. Tons per sq. in.	Ultimate Tons per sq. in. Stress.	(on 2 inches). Per cent. Elongation
A	22.6	38.8	27
	22.8	39.2	27
B	22.8	39.2	28
	22.4	38.8	28
C	22.4	38.8	30
	22.4	35.8	24

The treatment given to this rotor was as follows:—

(1)—Heated to 800° C. (1,472° F.), for 2 hours and cooled in oil.

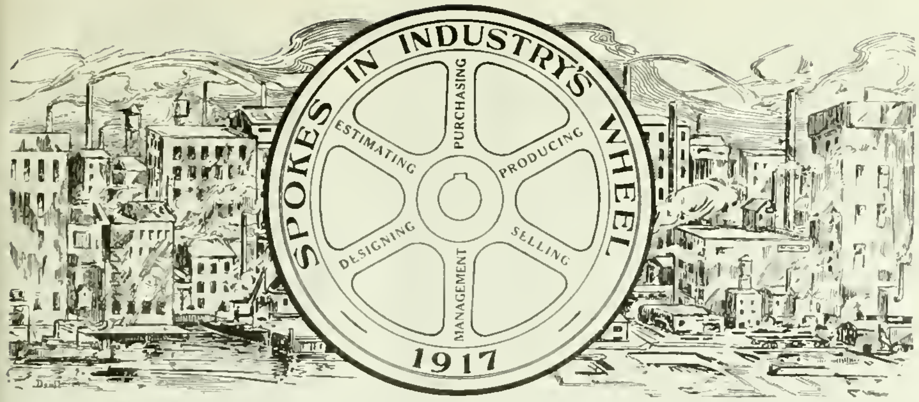
The centre part attained its heat in 19 hours 30 minutes, and the ends were uncovered after 15 hours 30 minutes, so that they attained their heat simultaneously with the centre part.

(2)—Heated to 550° C. (1,022° F.), in 11 hours 30 minutes, and kept at heat for two hours.

A very troublesome feature of large forgings which have been heat-treated is the distortion which takes place, due to internal stresses probably set up by the operation of quenching. On machining the forging, and especially on removing the outside surface, these stresses are partly relieved, and the forging distorts and takes up a new shape under the influence of the forces still left in the material, so that it loses straightness and generally adds very largely to the time occupied in machining. It is advisable on this account to rough-machine the forging after treatment, and then to re-anneal it before the final treatment is done. Allowance for this re-annealing can be made on the first testing, and where the final machining is intricate and accurate, it will be found to well repay the cost, since trouble in the machine shops due to distortion will be reduced to a minimum.

Hardening Nickel Steel Rifle Barrels.—The temperature generally used for hardening nickel steel rifle barrels is 1500 to 1525 degs. Fah.; and for manganese steel from 1475 to 1500 degs., but has to be varied, according to the chemical analysis of the different steels from which the barrels are to be made, says the *Iron Age*. The barrels are brought up to the required temperature in about one to two hours, depending upon their number and the heating factor of the furnace, and then allowed to soak at that temperature for a similar length of time, after which they are quenched in a tank of oil. The quenching solution, being oil, is not liable to crack or warp the barrels, and it should be kept at a constant temperature of from 70 to 100 degs. Fah.

Concerning Spring Steel.—Spring steel is said to become brittle when used as cathode in a hot cyanide solution, either sodium cupro-cyanide or simple sodium cyanide. The effect is more pronounced with the simple salt. Brass and phosphor-bronze are not affected. Brittleness is not produced by the liberation of hydrogen on the steel. The carbon content is not changed by the electrolysis. The crystalline structure is not changed by electrolysis. The brittleness is not produced in annealed wire; the brittleness is produced by use as cathode whether the wire is coiled or not bent in any way. The brittleness is not produced when the wire is used as anode, or when it is suspended in the solution without the passage of electricity.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

R. A. GURNHAM

DURING the past few years the fame of Canada has spread with increasing rapidity to all sections of the globe, and the commercial and industrial gates of this promising country are ever widening to provide for the greater volume of business that continues to flow in either direction. In common with every other country, the Metropolis generally becomes the transmission station through which the greater portion of the nation's energies or resources are distributed. Many good things and many evil things have been said of the Island City of Montreal, but while this cosmopolitan town may have its drawbacks, the subject of this sketch is, we trust, not one of them.

Robert Allan Gurnham, works superintendent with the John McDougall Caledonian Iron Works, Ltd., Montreal, was born in Montreal, May 25, 1886. Like many another good Canadian, Mr. Gurnham is proud to say that his ancestors are of good old British stock, both parents being of English origin; his mother born in the garden county of Kent and his father in Surrey County. Realizing the greater opportunities of a new country, both parents came to Canada in the year 1869.

Following his boyhood training in the public schools, "Bob" continued his education, as far as University Matriculation, in the Gault Institute of Valleyfield. The attraction of the engineering profession, however, soon induced our youthful "Spoke" to aspire to a knowledge of its practical side, and, at the age of fifteen, he entered the drawing office of the Northrop Iron Works at Valleyfield, serving three years apprenticeship with that firm. Wishing to acquire a wider experience in mechanical "adventure," R.A.G. commenced to hit the trail, his first stop being in the City of Montreal, where he became junior draughtsman to the Sleeper Engine Works. After being a "sleeper" for one year, he engaged with the C.P.R. car department, as one of the junior draughtsman, filling this position for one year. Following his railroad experience, Bob carried his kit to the John McDougall Caledonian Iron Works, and occupied the stool of a mechanical draughtsman for a period of two years. With the wanderlust still upon him, he took a position as mechanical draughtsman with the Hart-Otis Car Co., remaining with this concern for one year. During this period of practical concentration, our "Spoke" was also busy acquiring the technical essentials necessary for the attainment of the higher goals. While we cannot truthfully say

ROBERT ALLAN GURNHAM.

that he was making prohibitive use of the midnight oil, he nevertheless spent a fair proportion of his spare time in home study, having graduated in Mechanical Engineering at the American School of Correspondence in the year 1908. About this time he accepted a position with the Canadian Buffalo Forge Co., as chief draughtsman for one year; following which, he moved to Ogdensburg, N.Y., where he had charge of design and installation of special steam steering gear for the Century Engineering Co., remaining with this firm also for one year. Whether the attraction of his home town was greater than those of foreign fields, or that his "annual" had been completed, is not known, but we next find him back in the Canadian metropolis, as chief draughtsman for the John McDougall Caledonian Iron Works. After five years directing the engineering department, he was promoted to his present position of works superintendent.

Although a Conservative in politics, Mr. Gurnham's present duties do not permit him to take other than a passive interest in the "Affairs of State," although he is ever ready to support his inherent convictions. He is by religion an Anglican, and is also a member of Valleyfield Lodge, A. F. & A. M.; also belonging to the Canadian Order of Foresters. To renew the worn out tissues, our "Spoke" spends his recreation period in motor boating and canoeing, on Lake St. Francis. His military experience has been confined to a summer course with McGill C.O.T.C.

Among the more important undertakings with which Mr. Gurnham has been connected, was assisting at the design and installation of the heating and ventilation of the Princess Theatre, new Windsor Hotels, St. Annas School and Olier School in Montreal; also assisting in the design, installation, and operating tests of two-12 million gallon pumps, and two-30 million gallon pumps, for the City of Montreal. In keeping with the times however, the past two years and a half have been fully occupied by our "Spoke" in the active participation of shell making; the firm of John McDougall having been one of the first to engage in the production of 4.5 inch high explosive shell. Barring the ground covered in acquiring his engineering experience, Bob has not travelled extensively, his range being confined to short trips to the States, and business trips East to Halifax and West to Port Arthur.

Feeling the loneliness of a bachelor existence, Mr. Gurnham, in the year 1916, married Miss M. E. Tardif of Perce, Gaspe County; the couple taking up their residence at 376 Claremont Ave., Westmount.

Speaking of his engineering experience, Mr. Gurnham says "I cannot emphasize too highly, the necessity in our public schools, of giving our youth an opportunity of studying vocational training with the idea of preventing the forcing of square plugs into round holes in business life. I also think that every young mechanic or professional man should keep fully posted in his own particular line by a close study of the latest methods and equipment, by subscribing to and carefully studying at least one reliable technical or trade paper.

PAINT AND IRONWORK

By D. S. L.

IRONWORK enters to so great an extent into the construction and embellishment of buildings, that its proper treatment with paint is a matter of greater moment to the painter. He has to improve its appearance, as well as to protect it. Iron is very susceptible to the action of oxygen, or, in plain words, it soon rusts, and yet, since it is so much used for outside work, it is constantly exposed to the action of damp and changes of temperature. When used for the outside of buildings it requires, therefore, to be protected both from oxygen and from damp. The paint applied to it also requires protection from the action of light and from acid vapours Consequently several qualities are requisite in paint applied to ironwork. The paint should cling, and not be liable to chip and peel off. It must not corrode of itself, whilst it should be hard enough to resist damp; still it must be elastic enough to withstand the action of different temperatures on the iron, expanding and contracting with it. It must resist water and damp, acids and hard wear.

The pigment used must not be capable of affecting the iron itself. The vehicle mixed with the pigment should be able to protect the iron and to resist outside influences—damp and wear, changes of temperature, and deleterious gases. Those colors which have been subjected to the greatest amount of heat in their manufacture, or in other words, are highly oxidized, are the best for outside work, such as Indian red, Venetian red, and red lead. A red lead priming with a finishing color formed of a pigment mixed with varnish is the best for ironwork. Red-lead is by far the best possible priming for ironwork. When repainting the ironwork there is no need to attempt to scrape off the red-lead, for it clings to the iron firmly and does not scale, blister, or powder. Red-lead makes a first-class aquatic cement when mixed with glycerine—it is, therefore, an excellent paint for railings, bridges, glass houses, and other work that is much exposed to the ravages of variable climates.

Litharge stands next to red-lead, and behaves much in the same way, but it is not so full of body. Neither red-lead nor litharge requires driers, but litharge is only used as a drier. The reason for using red-lead is that it chemically hardens when only the requisite quantity of good oil is mixed with it. It then forms a lead soap, insoluble in water or air, and does not decompose anything it comes in contact with.

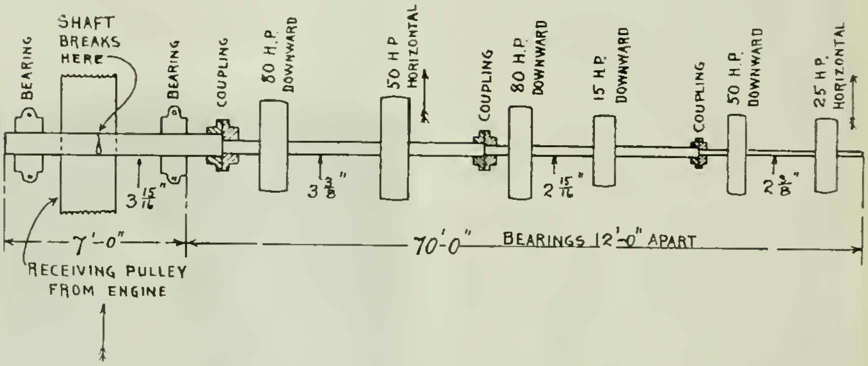
Red-lead mixed with two-year-old cold-pressed linseed oil, applied directly it is mixed (that is, before saponification has set in), will preserve iron for many years from rust. The first coat of red-lead does not completely fill up the pores; the second coat will do this, besides producing an enamel-like surface. The next staple color to these is turkey umber with raw linseed oil, which requires driers; with boiled oil the paint is liable to crack, blister and peel off. For interior work, alizarine, purpurine, bismarck brown, and several of the new permanent aniline colors might be used. Oxide of manganese may be used with the red-lead for a finishing coat. The black of the manganese combined with the red of the lead will form a chocolate, or it may be used with the oxides as a drier, and thus give a select tone of color too. Vermilion is a color which with stands heat and moisture. It is a sulphide of mercury, and is not affected by sulphuric acid vapors, and it does not scale or crack, unless the pigment is either mixed with bad oil or is adulterated. It must be painted flat and varnished afterwards, as oil itself does not agree with it. An iron black may be made from ground sulphate of iron. The oxides vary from a deep scarlet to a dark violet. The above-mentioned pigments give a range of colors that, being of similar nature, will mix without detriment. If a good priming is secured, say of red-lead, a range of permanent color of the same nature, protected with varnish, will give permanence, and a few brilliant colors will give a decorative effect. Such colors are necessary, for instance, for application to the ornamental ironwork of churches, for the banisters or rails of staircases, etc.

Objection has been raised to the oxides of iron, the opinion being expressed that, rust being an oxide of iron, these colors will only serve to still further oxidize the iron. Experience proves, however, that Indian red, Venetian red, etc., which are made at so high a temperature, stand very well, although they are not so preservative as red-lead, which excels all other pigments for ironwork. White-lead is slightly soluble in water. With the help of carbonic acid in damp places, it sets the iron rusting. Iron has a stronger affinity for oxygen, thus forming rust underneath the paint. White-lead has but little affinity for oil, is unable to resist the slow action of ammonia and damp, and has a tendency to oxidize the oil too quickly. The darkening of oil paint is explained by the fact that oil partly takes up oxygen from the pigment, thus burning or charring it. Zinc-white is not suitable for outside work; it is liable to scale, and does not unite well with the oil. It takes up carbonic acid from the air, and soon powders. Zinc-white, whenever used, requires more oil or binding than white-lead.

Iron must be thoroughly cleansed before being painted. One plan is to submit it to the action of water containing from one to two per cent. of sulphuric acid, then rinse with cold water, afterwards scouring with dry sand, and finally brushing the sand thoroughly away. Wire brushes are useful for ironwork. Paraffin oil well scrubbed in, will cleanse iron. A coat or two of varnish greatly helps to give permanence and lustre to iron. Encaustic varnish is used for inside work; it does not show up the inequalities of the ironwork, and imparts a refined appearance, but is never used for outside ironwork.

TROUBLE WITH SHAFT BREAKING

A CORRESPONDENT submits the following account of trouble through breakage of a shaft. We have a line shaft about 70 ft. long, which delivers a total horse-power of approximately 300, taken off the various pulleys in the directions shown in sketch. The shaft is driven by ropes received by a pulley on a 7ft. length of 3 15-16 in. shaft. The other shafts are respectively 3⅜ in. x 30 ft., 2 15-16 in. x 25 ft. and 2⅜ in. x 15 ft., the bearings being about 12 ft. apart. The rope drive is from a corliss engine and revolves the shaft at 290 revs. per min. Considerable trouble has been experienced through the 3 15-16 in. shaft breaking in the centre of the pulley hub, and has been repeatedly checked up for alignment without any defect therein. Any suggestions by readers would be appreciated.



LAYOUT OF SHAFT WHICH GIVES TROUBLE THROUGH BREAKING.

White Castings for Motor-car Work.—A mixture which has given satisfaction for motor-car fittings, and which can be polished the same as nickel-plated work, is as follows:—Copper, 50 lbs.; zinc, 35 lbs.; nickel, 15 lbs.; aluminum, 2 oz. The copper may be increased to 55 lbs., when the resulting castings are very hard and white.

STEEL INDUSTRY DEVELOPMENTS

The War-Created Stimulus given the Steel Industry is Reflected alike in the Nature and Application of New and Improved Equipment being Installed and Developed.

CLEANING BLAST FURNACE GAS*

MARKED differences in opinion have been expressed by engineers interested in cleaning iron blast furnace gases for use in hot-blast stoves and under boilers, with reference to the advantages of a hot-dry method compared with a cold-wet method.

One point at issue involves the sensible heat energy in the moisture contained in the gas. Some advocates of the cold-wet methods claim that the condensation and resultant removal of the greater portion of this contained moisture by wet scrubbing, spraying or similar method, results in a saving of some of this sensible heat energy, because water vapor has a high capacity for sensible heat energy and may carry from the exit of a hot-blast stove, for example, more heat units than are sacrificed or lost when the gas is cleaned by this cold-wet method.

Other advantages claimed for the latter method are: That gas burns more readily when it is free from moisture in any form; that, because gas is made denser by cooling and removing the moisture, it has a higher calorific value than hot gas carrying moisture; and that higher flame temperatures are obtained when the gas is cleaned by the cold-wet method.

Gas Heat Energy

The total heat energy in a gas includes the heat which may be developed by combustion (chemical energy), the heat due to the temperature of the gas (sensible heat), and the latent heat vaporization. The first type of energy may be called "the heat energy of combustion" and the second type "the sensible heat energy" of the gas. The heat energy of combustion is a function of the composition of the gases. For a definite composition of gases it is practically constant and can be readily calculated. The sensible heat energy of a gas depends upon the quantity of gas, the volume and temperature of the gas and the mean specific heat of the gas. The specific heat of a gas in turn depends upon the temperature of the gas and its chemical composition.

In this discussion one pound of a typical dry, clean top blast furnace gas is taken as the unit. It is assumed to have the following percentage composition by weight: CO_2, 21.00; CO, 24.00; H_2, 0.25; CH_4, 0.25; N_2, 54.50. The presence of moisture, dust and excess air is measured in terms of the quantity of this foreign material per pound of such dry, clean top gas. The sensible heat energy of moist, top gas is, therefore, according to our method of calculation the sensible heat energy of one pound of dry top gas plus the heat energy of the moisture which accompanies, and is in addition to one pound of the gases which constitute the dry top gas; that is, the heat energies are added together.

Moisture Measurement

In practice, the amount of moisture or dust in a gas is frequently measured in grains per cubic foot of gas. This method of measuring the moisture or dust content of a gas usually assumes that the moisture or dust is computed at a certain temperature of the gas such as 32 degrees Fah. Thus, taking one pound of dry top gas with 20 grains of dust per cubic foot of gas calculated at 32 degrees Fah. and 50 grains of moisture per cubic foot of gas calculated at 32 degrees Fah., the unit of gas would contain 0.034994 pound of dust and 0.087485 pound of moisture. The unit of gas considered would consist of a total of 1.122479 pounds of matter, and a calculation of the sensible heat energy of one pound of dry, clean top gas with the above moisture and dust content would involve the calculation of the sensible heat energy of 1.122479 pounds of matter.

This article, however, compares two methods of cleaning, the dry-hot and the cold-wet methods. Since both methods presuppose the removal of dust, it is not necessary to consider the sensible heat energy of the dust. In the example just cited the sensible heat energy would be calculated for 1.0487485 pounds of matter, the dust being excluded.

In the example given in the preceding paragraph the amount of dust and moisture per actual cubic foot of gas decreases with rise in temperature, because the gas expands. At atmospheric pressure one cubic foot of gas at 32 degrees Fah. will become two cubic feet at 523 degrees Fah., and in the example of moist, dusty gas, the dust content of 20 grains per cubic foot of gas calculated at 32 degrees Fah. will fall to 10 grains per actual cubic foot of gas at 523 degrees Fah., while the moisture content will fall from 50 grains per cubic foot, calculated at 32 degrees Fah., to 25 grains per actual cubic foot at 523 degrees Fah., though the percentage of dust and moisture per pound of dry, clean, top gas has remained the same. The measurement of the density of dust and moisture in a gas is, therefore, made by calculating how many grains of each a cubic foot of gas would contain if reduced in temperature to 320 degrees Fah., the pressure being standard at 760 millimeters of mercury.

Air Addition for Combustion

For purposes of combustion it is necessary to add a certain minimum weight of air per pound of the clean, dry top gas. After combustion the chemical composition and the specific heats of the gases have been completely changed. The datum point will be taken as 60 degrees Fah., and the sensible heat energy of the exit stove gases will be the amount of heat energy that the products of combustion of one pound of dry top gas plus the specified excess air plus the specified moisture entering the stove with the gas and air would emit when cooled from the specified temperature of the exit gases down to 60 degrees Fah. In these calculations it will be assumed that the moisture content of the stove exit gases is not great enough at any time to result in condensation of any of the water vapor at the temperature at which the mixed gases actually leave the stoves. In practice, the moisture content would seldom if ever reach such an amount.

Latent Heat of Water Vapor

The latent heat of the water vapor need not be considered because it is lost in any cleaning method which can be adopted. In the cold-wet method the latent heat of the water vapor is absorbed by the water used during the washing process, and is thus carried away by it; in the dry-hot method the latent heat of the water vapor is carried out with the stove exit gases and thereby lost.

Further, in using 60 degrees Fah. as the datum point for calculations of the sensible heat energy of the exit stove gases or of the blast furnace top gas after coming from the cleaner, it will be assumed the gas contains 5 grains of moisture per cubic foot of gas calculated at 32 degrees Fah. This means that the sensible heat energy is referred to that of the same gas practically saturated with moisture at 60 degrees Fah. Such a datum point is convenient because any kind of a gas cleaned by the cold-wet method usually comes out at about 60 degrees Fah. and is practically saturated with moisture. As our comparison is made between a dry-hot and a cold-wet method of cleaning, it is natural to assume conditions prevalent in the cold-wet method as the datum point.

Consider one pound of dry, clean, top gas at 700 degrees Fah., containing 20 grains of dust and 25 grains of moisture, both calculated per cubic foot of gas at 32 degrees Fah. Our unit of dusty and moist gas weighs 1.078736 pounds. It is found that the sensible heat energy in the one pound of top gas and that in the moisture (which would be lost if the gas passed through a cold-wet cleaning apparatus, thus reducing its temperature to 60 degrees Fah.) would be 174.69 B.t.u.—Qt. By the cold-wet method of cleaning that cools the gas to 60 degrees Fah., the above Qt units of heat energy are lost for every pound of dry top gas, plus a specified moisture density.

*From a paper presented at the meetings of the American Institute of Mining Engineers, New York, Feb., 1917, by L. Bradley, H. D. Egbert and W. W. Strong.

In the dry-hot method of cleaning, no material lowering of temperature of the combustible gases for the stoves need take place. This condition is practically feasible when the electrical method of cleaning is used because the electrical precipitators need not be more than 15 or 20 feet in length. The length of the gas mains and connections need not, therefore, be greatly increased, and, furthermore, they may be insulated so as to conserve the heat energy of the gases.

In the dry-hot method of cleaning the 25 grains of moisture per cubic foot of gas remain in the gas and are carried into the stoves and then out with the products of combustion. The only difference between the exit gases from dry-hot cleaning and cold-wet cleaning is that in the one case there are 20 grains of moisture per cubic foot of gas standard more than in the other case. Let us assume that the exit gases leave the hot-blast stoves at 600 degrees Fah., which is a fair average. With the hot-dry method of cleaning these gases will carry away 8.83 B.t.u. of sensible heat energy for every pound of dry top gas over and above what the same gases would have carried out had they been cleaned by a cold-wet method, due to the greater amount of moisture left in the gas when cleaned by the hot-dry method. Let this energy be Qe. The saving in sensible heat energy by the hot-dry method of cleaning as compared to the cold-wet method is: Qt — Qe=174.6 — 8.83 = 165.86 B.t.u. per pound of dry top gas.

In the above comparison any energy changes due to expansion or contraction of the gases can be neglected because the exit gases are under practically the same condition of pressure and temperature for both methods of cleaning.

Assuming a ton of iron to represent a production of 12,000 pounds of such typical top gas, a hot-dry method of cleaning the gases would conserve: 12,000 (Qt — Qe) = 1,990,320 B.t.u. per ton of iron.

In some ores a considerable amount of compounds of potash, zinc, lead, arsenic, antimony, etc., may accompany the compounds of iron, copper, etc., for which the ore is being smelted. Under present conditions this more volatile part of the ore may be carried away in the top gas. A dry method of cleaning may allow the recovery of certain of these volatile compounds, thus making commercially possible the treatment of a greater variety of ores. At the present time the application of the electrical method of cleaning blast furnace gas from iron ore containing zinc is being developed and other problems similar to this are also under consideration.

Under practical operating conditions, many factors relating to the cleaning process must be considered. A few of these may be briefly discussed. The cold-wet process of cleaning is usually more or less automatic in operation and requires comparatively little attention. Rather large quantities of water are used and considerable power is consumed in handling this water, and in forcing the gases through the system. The washers are comparatively large and the initial expense of installation is also large. In some instances, a problem arises as to the disposal of the muddy water, it often being illegal to allow this contaminated water to run into the streams, while in other instances water is not abundant and its use for gas cleaning may be prohibitive.

Electrical Method of Cleaning

There is a hot-dry method of cleaning that promises to be very advantageous for the purpose of cleaning these gases The electrical precipitation processes make use of a high-tension electrical discharge which sweeps out the suspended matter from the surrounding gas. The electrical method does not cool the gas, it precipitates the suspended dust in a dry state, thus making it easy to reclaim this material. The operation is practically automatic and the energy consumption is small.

The cleaning power of the electrical method is said to be practically complete, in many instances being as high as 99 to 100 per cent. The degree of cleaning is greater than that usually obtained by wet methods in general, and is ample for stoves and boilers. Indeed, the results of recent tests have indicated the probability that, even with a single pass precipitator, the gases would be cleaned to the degree required by internal-combustion engines.

ELECTRIC STEELS

By Mark Meredith.

THE war has speeded up in a remarkable degree innumerable developments which were previously hanging fire or proceeding at a leisurely pace. Among these the electric furnace is noteworthy. In the first half of 1914 electric furnaces were certainly being installed here and there in steel works, but in an experimental or very tentative way. The war brought an increased need for alloy and special steels, for steel castings, and also for means of extracting chromium and nickel from the vast quantities of steel turnings containing these alloys, which are being made in the munition shops. For all these purposes the electric furnace has proved itself particularly valuable, and in the last three years the number of electric furnaces in use in the world has increased with rapid strides. According to a recent computation there were on January 1st, 1917, in the United States, 136 such furnaces, in Great Britain 88, in Germany 52, in Sweden 40, in Italy 29, in France 20, in Canada 19, in Austria Hungary 18, in Russia 16, and in other countries 44. In this computation, figures for belligerent countries are probably underestimated, but accepting the list as given, there are now at work in the world 471 electric furnaces producing steel of one kind and another.

The capacity of the furnaces varies greatly, and no precise figures are available for the total rate of output at the present time, but it is estimated on sufficiently good grounds that within a year or two the world's output will reach 1,000,000 tons per annum. This estimate is for special steels and castings only, melted up from cold charges, but the electric furnace is also being extensively used for the refining of steel charged into the furnace in a molten state, and if this process should prove generally advantageous, the installation of electric furnaces may be very greatly accelerated. The comparatively large number of furnaces in use in Sweden is, of course, accounted for by the fact that the generation of electricity by water power is proceeding rapidly in Scandinavia, a development highly favorable to the use of electric furnaces. This fact has promoted in Sweden the use of electric furnaces for quite another order of metallurgical work—smelting of pig iron direct from the ore. At least seventeen furnaces, with capacities ranging from 3,000 to 6,000 h.p. are at present at work under construction in Sweden in this connection.

An important feature of the electric steel process is that, by means of it, high quality steel can be produced from materials of a much lower grade than is possible by any other process, so that even though the cost of current exceeds the cost of fuel, it is still possible for the product of the electric furnace to be sold at a competitive price. It remains to be seen how far the electric furnace will be able to hold its own when normal conditions return, but there is every indication that it has taken a permanent place in the process of steel manufacture.

By-Products Recovery.—Nearly all modern by-product oven installations recover their benzol, toluol, etc., in the form of 65 per cent. crude benzol. In former days this crude benzol was transferred at once to the washer and from thence to the rectifying still, whence 90 per cent. benzol, 50/90 benzol, toluol, and naphtha were produced. The modern practice is, however, to distil this unwashed crude benzol in a still of simple construction, and to separate an unwashed benzol fraction, an unwashed toluol fraction, and an unwashed naphtha fraction, the residue being run into a pan where the naphthalene solidifies out on cooling. The benzol fraction will be the first distillate up to the point at which the product at the delivery gives its first drop at about 105 deg. Cent., and the toluol fraction the second distillate up to the point at which the delivery product gives its first drop at about 124 deg. Cent. These three partly rectified, unwashed fractions are accumulated in separate tanks, and are in due course blown or pumped separately to the washer, where the material is agitated first with acid and then with caustic soda.

"Say pa, I bet Bobby Smith ten cents to-day that you could lick his dad in fifteen minutes—so be sure and keep Saturday afternoon open."

FRICTION AND LUBRICATION OF SHAFTING

Vulcan Staff Article.

MACHINERY and shafting in general, including the fittings, principally comprises details which are in sliding contact with each other. If clean metallic surfaces are placed in absolute contact, and one part slid over the other, excessive friction is developed, by which serious resistance to motion is caused, and the surfaces are wasted by abrasion. In order to minimize frictional resistance and to prevent wear (or to reduce this to a negligible amount), the use of a lubricant is adopted in such a manner as to effect a definite separation between the surfaces, although, at a glance, they appear to be in contact with each other. The lubricating agents commonly adopted are oil or grease in various forms and conditions; also soap, tar, and other fluid, semi-fluid and more solid substances.

Lubricant Action

The film of lubricant acts in much the same way as a series of infinitely small friction rollers. Obviously the accuracy of action, and, therefore, the efficiency of the result, must depend upon the perfect accuracy of the fitting of the mechanical surfaces in each particular case. In connection with a shaft rotating at a high speed, the two surfaces, convex and concave, must be true to circular form. In practice a plain shaft, as left by the turning tool, is not necessarily circular in cross-section, for various reasons connected with the operation of turning in the lathe. Such a shaft is invariably finished by polishing in which a stationary surface of emery is applied, but this cannot effect any improvement in regard to circularity. Careful grinding of the shaft will, however, correct the circularity of the surface; with this object the shaft should be slowly rotated and the cutting effected by a rapidly-rotated wheel of emery or other abrasive material.

Obviously, the ultimate accuracy of the work depends, not only upon the skill and attention of the workman, but also upon the accuracy of rotation of the shaft (preferably upon hardened and ground centres), and upon the truth of rotation and freedom from vibration in connection with the revolving grinding wheel. The matrix or bearing surface by which the shaft is supported should also present an accurate surface, and where the matrix is of hard material it is necessary to adopt measures corresponding to those applying to the shaft. If, however, bearings of soft white metal are adopted, the surfaces of these will adjust themselves by wear in a comparatively short time. When the operation of correcting the circularity by grinding is properly conducted, it incidentally removes a thin coating of metal, which may be said to have been loosened or adversely affected in the principal process of turning. This metal may be compared to an infinitely minute coating of valvet, the minute fibres of which are all bent away in the same direction. By the process of grinding, a superior surface of solid metal is presented whereby the frictional resistance to motion is reduced and the vibration or deflection of the centre line of rotation is eliminated.

Ground Bearings for High Speed

All bearings which are required to rotate at a high speed should be finished by grinding, as a point of necessity. The amount of advantage to be thus obtained in connection with parts which rotate at a low speed may be correspondingly small; but in all cases, great care should be devoted to an adequate degree of accuracy in the bearings. The bearings of a crank shaft, even if working at a low speed, are of sufficient importance to call for finishing by accurate grinding in all cases in which the contractor possesses the necessary appliances. In the absence of such appliances, the shaft is finished by turning and polishing, and some engineers are strongly of opinion that better results are obtained when these operations are performed with a shaft rotating in the same direction as it will rotate in its ultimate working position. This can only be explained on the assumption that the incipient fibres of metal are pressed aside by a tool, and left somewhat in the manner of a pile on a velvet cloth; as above referred to. Consideration of the foregoing points will assist in the study of any question affecting the resistance to rotative movement in shafting. The same may be extended to movements of surfaces of revolution of any kind, and also to plane surfaces.

Direct Frictional Resistance

The amount of direct frictional resistance in pairs of solid bodies, as developed when one object is laid upon the other and slid along it, is proportionate to the magnitude of the force by which the one is pressed or held against the other. In the case of dry unlubricated surfaces, the frictional resistance is about one-fifth of such weight or force. This quantity is generally given in the form of a fraction, as .20, which is applied to the amount of pressure at right angles to the surface. This fraction is termed a coefficient of friction, and it is largely reduced by the use of a lubricating agent. For all metallic surfaces, plain or revolving, and which are lubricated by anointing with tallow, lard, or olive oil before placing in contact, the coefficient of friction has been found to be from 0.07 to 0.08. In good modern practice, the majority of revolving and sliding surfaces are lubricated with a copious supply of thin oil, whereby the coefficient of friction is reduced to its lowest limits. About the year 1884, B. Tower made a large number of experiments in which the coefficient was brought down to 0.001 or 0.002, equivalent to a fifty-fold reduction upon the results above given.

Types of Shafting Lubrication

The two principal types of shafting lubrication now adopted are by pump supply and by rings. In pump supply, means are adopted for the collection of oil which leaves the bearing, also to conduct it to a pump for return to the bearing so that the oil is used over and over again indefinitely. In the simple case the used oil may be collected in the bottom of a wall box, or equivalent position. This should be effected with due regard to the following points:—

(1)—The collection should be complete without leakage or distribution by spray or otherwise. Most frequently some loss is incurred by faulty fitting or arrangement. This loss is objectionable from an economical point of view. In a closely-proportioned detail, it may involve the exhaustion of the supply of oil whereby risk of heating and serious damage may be involved. Oil which thus escapes is very likely to cause damage to walls and foundations, and almost certainly it presents a most objectionable eyesore.

(2)—The means of collection and pipes by which the oil is conducted to the pump should be so arranged as to avoid deterioration of oil by dust from the atmosphere. Dust from the atmosphere may be excluded by the adoption of screens of sheet steel, well fitted against both sides of the wall box, and such other openings as may exist. These must be arranged for convenience of opening or taking apart whenever required.

(3)—It is an advantage to have a short break in the delivery pipe by which the current of oil can be placed under observation at any time. For this purpose it may very well be protected by a glass tube. This gives an opportunity for observing the quantity of oil delivered, and its condition with reference to clearness and limpidity.

(4)—The collectors should be thoroughly cleaned by scraping and brushing down to the bare iron, so that all surfaces with which the oil can come in contact are clean; also this operation should be extended to any upper surfaces from which foreign matter can possibly drop. This applies more particularly to sand, which, although it may be comparatively soft and easily removed, is often allowed to remain. The same observation, however, applies to hard sand, as this is liable to soften by extended contact with oil, and, moreover, it is at all times liable to detachment by a blow with very serious results.

Ring Oiling

Ring oiling is effected by the use of a ring or endless chain of greater diameter than the bearing. The top brass and the cap of the bearing are arranged so that the rings can lie upon the revolving shaft, and can be driven by frictional contact when the shaft is rotated. The whole arrangement, including the bottom shaft, must be so designed as to allow the ring or chain to be rove along the shaft into its position; or alternatively, the ring or chain may be arranged for division into two parts for placing in position or removing therefrom. The bottom brass is sometimes divided into two to clear the ring, but this is not necessary or desirable. The ring or chain must possess sufficient weight to originate an amount of friction sufficient to drive the ring with its load of adherent oil, and also to overcome the resistance of oil in the oil well. The oil well should provide sufficient depth of oil to load the ring without dipping so deeply as to pick up the dregs of oil. In connection with this type of apparatus, the necessity for removal of dirt, sand, and foreign matter generally, as already explained, applies to the fullest possible extent. The cap of each bearing should be so arranged as to give a good view of the oil when passing over the top of the bearing. Here also the view is necessary for estimating the quantity and condition of oil.

A certain amount of cloudiness develops in oil after repeated use. This is principally due to wear of surfaces, but its quantity should be negligible except as to a short period after starting up new work. The amount, of course, depends principally upon the degree of excellence in the fitting and adjustment of bearings whereby the amount of frictional resistance is minimized. Oxidation by atmospheric influence should be kept in mind, although it does not frequently occur with the use of good oil; but, on the whole, it is better to avoid exposure of any considerable amount of oil surface to the air.

Choice of Lubricating Oil

In the choice of lubricating oil, one of the most important conditions is the degree of completeness with which the frictional resistance is eliminated by the use of the oil. As a rule, oil which is supplied for lubricating purposes is not of a character which is prone to oxidation, but an occasional consignment may give much trouble by gumming, which arises in this way. Excessive frictional resistance is often due to excessive viscosity in the oil, which is equivalent to a deficiency in the degree of fluidity most appropriate to the work of the particular bearings in question, and chiefly with regard to the pressure per square inch to which the bearings are exposed and to the surface speed adopted. A heavy load requires an oil of high viscosity. High speed may facilitate the use of thin oil, and thereby effect a reduction in frictional resistance, but any deficiency in the workmanship is attended with greater trouble in case of the high speed.

Cases have been recorded in which a change of oil has been attended with an increase of 15 to 20 per cent. in the amount of power which is required to drive a given quantity of machinery. If the engine happens to be very closely proportioned to its work, the steam and fuel consumption will rise in a proportion distinctly greater than the increase in the horse power. Obviously, if the additional power is confined to the shafting it may be disclosed in the most striking manner by the indication of the friction load, with all machinery stopped. It is, however, improbable that an increase in the power of the amount stated can be incurred on shafting alone, but there is every reason to believe that it is often incurred in connection with the total load, on account of machinery with the hundreds of thousands of spindles which are used in textile mills.

Power in excess, which is above referred to, is in every case represented by heat which is generated in strictly accurate proportion to the amount of power consumed, and such heat is distributed over the details in proximity to the surface upon which the resistance is developed. Therefore, careful observation by touching the bearings will, in many cases, suffice to show a distinct difference between the moderate heating due to ordinary work, and the excessive heat due to inordinate resistance to motion in bearings, spindles, and other surfaces which are subject to friction.

Excessive resistance is, moreover, often caused by defective alignment of bearings, either originally or as consequent upon subsidence in the ground and foundations. Such variations in alignment may be found either in a horizontal or a vertical direction. Experience appears to show that few large works have the bearings accurately adjusted either as to lines or levels. In this connection a hypothetical example may be taken in a shaft of 4 in. diameter, which is carried in bearings placed at 10 ft. centres, and which is deflected by ¼ in. from the accurate line in the middle of a length of 20 ft. This bearing will have an additional load of 394 lbs. imposed upon it by the deflection, and a further counter-load of 394 lbs., which latter is principally upon the two bearings next adjoining the one in principal question, or a total abnormal pressure across the shaft of 788 lbs.

At a speed of 200 revolutions, and with the full coefficient of .075 as appertaining to bearings which are occasionally oiled by manual attention, the loss by abnormal friction becomes serious, amounting to .375 horse-power. This loss is, however, very frequently exceeded by reason of the stiffness corresponding to the shafts of larger diameter, and also by reason of greater derangement of centres. In a recent case, a serious error of this kind was discovered in the second motion shaft of a large engine, as to which evidence shows that the derangement had existed and caused much trouble during many years.

Erection and Correction of Shafting Bearings

In connection with the erection and the subsequent correction of the bearings of shafting, the first point is in regard to the alignment in ground plan, as to which any fair mechanic will have no difficulty in stringing a line along beneath the shaft and straddling the shaft with a plumb-line on each side of the shaft near to each bearing. The levelling of the shafting is attended with more difficulty than the horizontal alignment, on account of the fact that special levelling apparatus is required. Ordinary levelling from one bearing to another by an ordinary straight-edge and with a hand-level is attended with difficulty and loss of much time, and is, moreover, not reliable in its results.

The majority of careful millwrights when engaged upon levelling over long distances use a water level, the principal elements in which are a long flexible tube and a terminal piece at each end in the form of a glass tube. The apparatus is filled up with water so that the surface shows in both tubes at the same level. This apparatus is very clumsy for use in most favorable conditions. It is difficult to ensure accurate transference of levels from the surface of the water in the tubes to the actual bearings of the shaft, and it is most essential that all possibility of air locks, bubbles, or other interruptions in continuity of water in the tube and connections should be fully assured.

In all ordinary cases, the use of an ordinary dumpy level, as used in survey work and heavy engineering construction, gives, however, much better results, and in a more convenient manner than any water level. In the majority of dumpy levels, the cross lines are given by thin spider webs, which are difficult to adjust in position and are liable to frequent fracture. The writer calls to mind one case, in a work of importance, in which the cross line was carried away by a strong gleam of sunshine and the work consequently stopped, causing great inconvenience. Experience of this kind will account for the reluctance of millwrights in adopting the use of such a level. In good modern instruments, however, the cross lines are given by ruling upon a glass plate, which is beyond comparison more reliable. The use of a dumpy level for this purpose is generally conducted by giving a mark for each bearing, all such marks being accurately placed at the same level. The quantity of shafting and bearings is usually much greater in a weaving shed than in other situations, but the shafting in such positions is, however, more flexible on account of its comparatively small diameter. Very great improvements have been effected by correcting the shafting on results obtained in this way.

NEW COAL WASHING PLANT

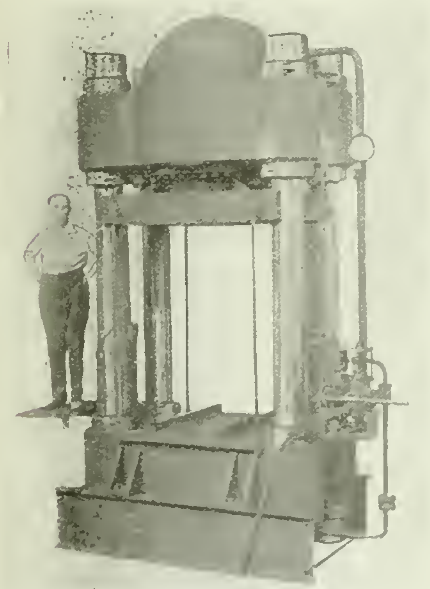
THE installation of a new type of coal-washing plant at the Glamorgan collieries, Llwynpia, is being attended by extremely successful results, and is likely to lead to further important developments in the mining industry in the direction of dealing with what is known as "sump slurry," a coal dust previously regarded as waste. By this process the invention of J. M. Draper, of Manchester, material is secured for the production of high quality of coke. During the process of washing practically no coal, it is said, is lost, and dirty coal containing upwards of 27 per cent. of ash can now be washed down to 8½ per cent. and even lower. The machinery at the Glamorgan collieries is practically automatic, and is turning out 40 tons of the finest washed coal per day, whilst the cost of working is low. It can be applied to dealing with the debris in colliery tips, so that there is a prospect of recovering from these huge banks the large proportion of coal which they contain.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

HYDRAULIC SHINGLE FORMING PRESS

THE illustration shows a hydraulic press of 1,500 tons capacity, which has been built expressly for the forming of fireproof shingles from an asbestos mixture. It is a recent product of the Hydraulic Press Mfg. Co., Mount Gilead, Ohio, and will be used by a Japanese manufacturer of asbestos



1500-TON INVERTED, ASBESTOS SHINGLE PRESS.

shingles. Interest attaches to the method of pressing these shingles, which requires the special equipment shown in the illustration. The asbestos, after being thoroughly mixed with other ingredients, is formed into layers and placed upon drainage plates. Each plate consists of a steel plate, a sheet of woven wire and a sheet of duck cloth. A number of these plates with a layer of the mixed material to be pressed on each, are stacked upon a steel truck which is then run into the press to receive the pressure for the purpose of extracting the excess moisture and to form each layer to a uniform thickness. The ingredients are also thus pressed into a solid mass. The formed slabs can be used in their original size, 42 inches square, or may be sawed into smaller pieces.

The track running through the press is not attached to the base of the press, but is mounted on a frame, which is supported from above by four rods working through lugs cast on the platen. These rods have lock nuts on their upper ends by which the rods are adjusted to support the track at its proper level. When the platen is at its highest point, the track is lifted a short distance from the pressure bed. As the platen travels downward, the track is lowered upon the pressure bed, and the platen continues to travel over the rods which pass through the bearings in the platen lugs. The wheels of the truck are so mounted that the bottom of the truck is slightly below the bottom of the track. When the platen starts down, it lowers the four supporting rods with the track, while the truck bottom takes a bearing upon the press base, the wheels being released of all strain during the pressing operation. When the platen is returned, it again lifts the truck from the press base by raising the press track under the wheels and level with the track on the floor so that the truck can be run out of the press.

It will be observed by the illustration that the press is solidly built, steel being used throughout in its construction. The strain rods are made of heat treated forged steel, and are machined to a diameter of 9 in. The heads of the strain rods are forged on. The heads take a bearing against split steel collars. The strain rod lugs on the cylinder and press base being bored, a perfect alignment is obtained through screwed strain rod collars. The press has a pressing surface of 42 in. x 42 in., and a daylight space of 60 in.

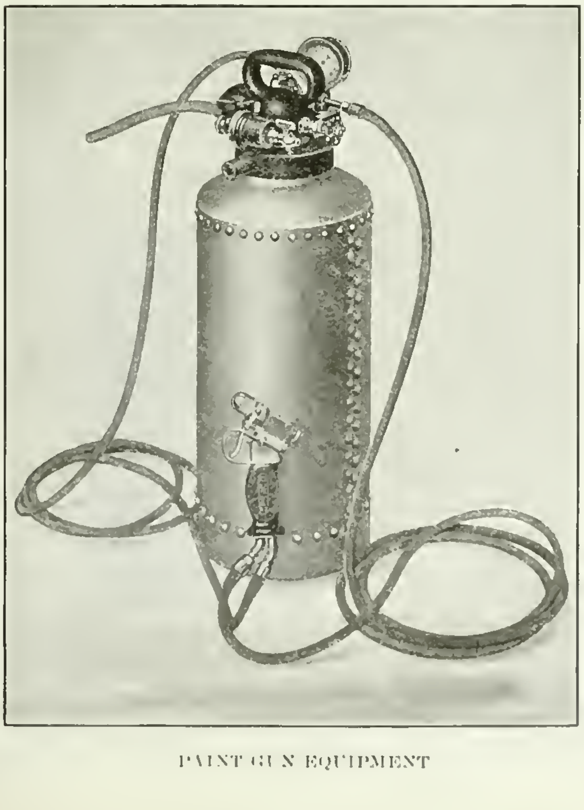
All of the operations of this press are controlled by one 2-in. four-way poppet operating valve. The press has two small push cylinders, which return the main pressure ram after the pressing operation has been completed. These are mounted upon the base of the press between the strain rods. The push rams have a diameter of 5 in. and a run slightly greater than that of the main pressure ram.

PAINT GUN EQUIPMENT

APPARATUS for applying paint and other liquid coatings by means of compressed air has been developed to a point where its use has become synonymous with efficiency, and its field practically unlimited. Included in its range of work are such diversified products as railroad cars and scientific instruments, art metal work and foundry cores, agricultural machines and pianos. The apparatus illustrated herewith is adapted for use in shop, field or laboratory, and may be adjusted for spraying the highest grade of varnishes and lacquers, as well as heavy asphaltum and structural paints, producing finely finished surfaces without streaks or brush marks. It is also adapted for applying heavy durable coatings to rough structures.

The complete equipment consists of the paint gun proper, connected by flexible hose to a portable unit combining in a compact rugged form the material container, air dryer and strainer, pressure control attachment and pressure gauge. After the portable control head has been adjusted to meet the conditions of air pressure, thickness of paint, etc. the operator has complete control of the outfit by means of the trigger on the paint gun proper. The gun proper is mounted on a pistol grip, to the butt of which the air and pipe lines are connected. Two adjustments only are necessary—the round cap at the nose, which screws out and in, regulates the amount of material, while the knurled stem at the rear controls the amount of air. The control trigger acts on both air and material, regulating the amount sprayed from zero to maximum. The total weight of the gun is slightly over one pound.

The control head on the tank comprises a pressure gauge, adjustable reducing valve, and air filter and strainer. Where light substances are being sprayed, the gun may be connected directly to the air pressure line instead of the tank.

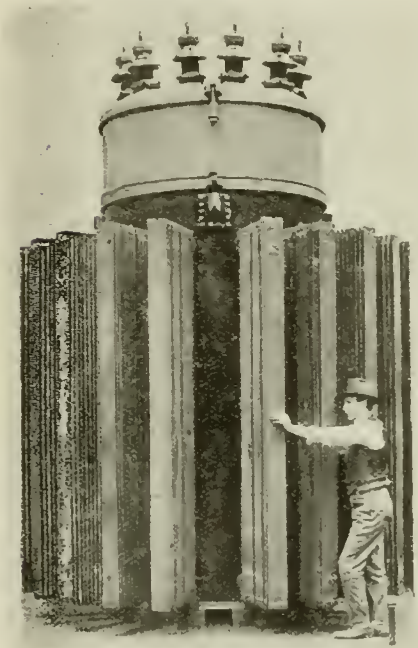


PAINT GUN EQUIPMENT

and the substance in use is placed in an overhead container and fed by gravity. This equipment is manufactured by the Spray Engineering Co., Boston, Mass.

GIGANTIC VOLTAGE REGULATOR

THE accompanying illustration shows what is claimed to be the largest piece of apparatus of its type which has ever been built. It is a self-controlled, induction feeder voltage regulator of the oil-insulated self-cooling type and was recently completed by the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., for a large power Co., in the



GIGANTIC VOLTAGE REGULATOR.

Southern States. It is rated at 600 k v a., 3-phase, 60 cycles, 13,200 volts, with 10 and 20 per cent. regulation at 262 and 131 amperes, and is designed for operation out doors with full-automatic control self-contained. When installed, the regulator will be connected to the low voltage side of a 6,000 kva. bank of 44,000 to 13,200 volt transformers on the power Co.'s line, and by its use the power from the line will be delivered to the consumer with the voltage maintained continuously at normal value.

CYCLE COUNTER OR TIMING DEVICE.

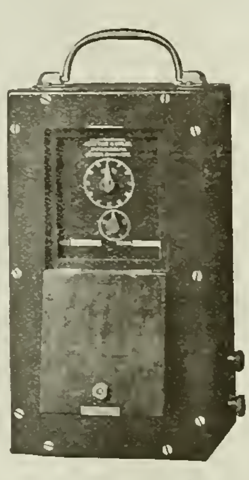
AS IS generally known, it is not possible to obtain satisfactory results in the testing of time elements of high accuracy relays and of circuit breakers, with a stop watch, particularly where the selective action of the circuit breaker is essential. For this purpose, the Westinghouse Electric & Mfg. Co. of East Pittsburgh, Pa., has developed the cycle counter illustrated, which is a device for indicating definitely the number of cycles required for the relay to close its contacts.

The mechanism of this timing device consists essentially of an electric self-winding clock, the escapement of which is operated by an alternating current oscillating magnet instead of a pendulum or balance wheel. At each cycle, one tooth of the escapement is released. The self winding clock periodically rewinds by means of power supplied from a shunt connection to the circuit when the cycle pointer has made 60 revolutions, the equivalent of 3,600 cycles. This arrangement keeps an even tension on the escapement. Thus, the escapement magnet is not depended on to drive the indicator, but simply to regulate its speed. The power for driving is furnished by the clock mechanism.

In operation the cycle counter is connected in series with the relay on a circuit adjusted to give the current value at which it is required to test the relay. When the circuit is closed, the "cycle" pointer begins to revolve, one step per cycle, and continues to do so until the contacts are closed. The instrument acts as though it had no inertia; that is, it starts the instant power is applied and stops the instant power closes.

Although primarily designed for use in testing or adjusting time-element relays, this instrument is suitable for a great variety of testing. Its particular field of usefulness is for measuring elapsed time intervals of time too short to be satisfactorily observed with a stop watch and where readings in steps of one alternation are sufficiently accurate, obviating the use of complicated and expensive apparatus such as chronographs or oscillographs.

Given a known frequency the readings can be reduced to seconds if desired. Conversely, by connecting the instrument to a circuit for a definite period of time the frequency can be determined. By adding contacts to machine tools, elevator machinery, etc., the time required for various functions can be determined. It will also be found useful in many laboratories and test rooms for timing purposes.

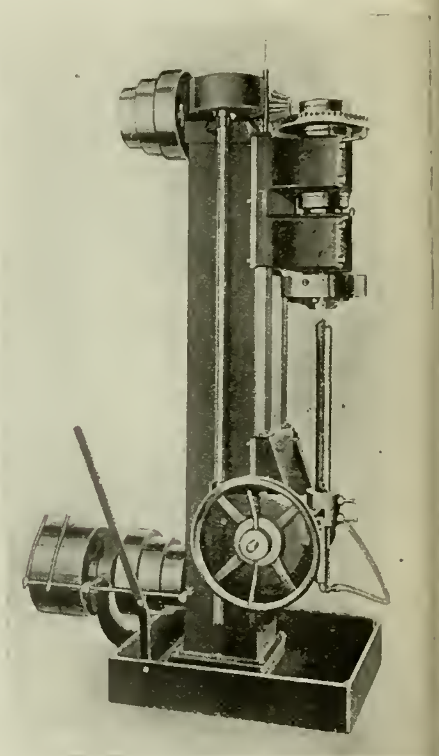


CYCLE COUNTER OR TIMING DEVICE

SPINDLE-DRILLING MACHINE

THE almost universal demand for hollow spindles in lathes and similar machine tools has created a field for machines which are specially designed for deep hole drilling. A drilling machine for work of this class has been placed on the market by Charles Stecher Co., Chicago, and is illustrated in the accompanying engraving.

It is of the inverted type in which the work is placed above the drill to provide free escape for chips, which action is further facilitated by lubricant supplied through passages to the cutting edges by force pump. The work-carrying spindle is mounted on a fixed carriage carried on the face of the main column, and is driven by bevel gearing at its upper end; the lower end carries a chuck for holding the work which may extend to 30 in. in length, above which it is desirable to use an additional chuck on the upper end.



HOLLOW SPINDLE DRILLING MACHINE.

The drill is mounted in a tool carriage, gibbed to the column face and provided with power feed operated by gearing from the upper drive shaft, the feed being varied as required by using gears of suitable ratio. Drive from the pulley shaft is by three-speed cone pulleys. Ball bearings are fitted to both horizontal shafts, and ball-thrust bearings to the work spindle. The principal dimensions are distance, chuck to drill holder, 32½ in.; hole through spindle, 4¼ in. dia.; swing over bed, 14 in.; floor space, 32 x 48 in.; weight, 1,800 lb.

A POST-WAR PROBLEM OF LABOR

THE introduction of shell manufacture into Canada, created a new phase of enterprise which, up until three years ago, had practically been an unknown factor in this country's industrial activities. The rapid expansion of munitions making, coupled with the drain upon the man power of the land, had the effect of causing a temporary dearth of skilled mechanics in many lines of manufacture. This feature of an unprecedented situation threatened the success of an obligation suddenly undertaken by Canada's captains of industry. During the early period of the war, when the call for volunteers was meeting with a wonderful response, our factories were being depleted of the trained men upon whom much reliance had been placed for the achievement of the new task; that of producing munitions for the Imperial Government.

Time and determination, however, have ever proved the master of circumstances, and while shell makers were confronted with many obstacles during the incipient stages of the undertaking, these very obstacles were eventually the stepping stones by which the desired goal was ultimately attained. The inability to acquire desirable information regarding the manufacture of shell was one of the chief drawbacks to the more rapid development of the new industry, and the first shell makers were forced, to a great extent, to rely upon their own personal experience and perception when equipping their plants for the production of the smaller size yet diverse type shell. Our metal-working firms had never before been called upon to produce on such an extensive scale, besides, little time was permitted to form a plan of action to meet the need. Equipment was apparently the essential factor, and a feverish start was made to obtain the machines most suitable for the purpose. Guided by previous practice in other lines of engineering output, the tools ordered for the new venture were naturally of standard pattern, with few or any of the auxiliary parts eliminated. The urgency and magnitude of the demand for these tools, and the inability of the machine tool builders to deliver equipment, created an unprecedented situation, the result of which has been the means of revolutionizing, not only the shell making industry, but is likely to establish a new standard in future engineering practice.

Probably never before in Canada's history have the resources of plant and individual been more rapidly developed than during the past three years. Instead of the delay in the delivery of equipment proving a drawback, it has probably been a blessing in disguise. Had sufficient standard tools been readily available at the commencement of the shell game, there is a large possibility that the increased production would not have been as rapid as the changed conditions have proved it to be. Unable to secure standard tools, shell makers began to equip existing machinery with special attachments or devices for the accomplishment of certain operations. Scrap heaps were explored and machines that had been "dead" for years were pressed into service, with such remarkable success that a foundation was started upon which a new and highly efficient line of special single purpose machinery was designed and constructed.

The evolution of modern shell making equipment, from the impromptu attachment to the special purpose machine, has been a great collective engineering achievement, and will likely have considerable bearing upon future manufacturing methods; but the changed status of the workman may create a situation unique in the field of engineering, and one that will require the best efforts of plant executives to solve. Owing to the methods of manufacture, and the development of single purpose tools for specific operations, the problem of unskilled labor has not been as complex as it might otherwise have been, as experience has shown that men, and also women, who had no previous knowledge of machine shop practice, have been equally capable with skilled mechanics in the operation of special machines. The question, however, is: What effect will this have on post-war manufacturing conditions? The knowledge acquired in the operation of machinery by the majority of those now working on munitions, will, when the "game" is over, be a factor that must be included in the problem of future readjustment. It must be conceded that large numbers of present shell workers will class themselves as "machinists" when the war is over, and normal conditions again prevail.

Where manufacturing is carried on by the separate operation system, the value of machine operators cannot be over-estimated, but the possibilities of domestic production on as vast a scale as the shell making of the past two years, is so very remote, that the services of "shell mechanics" cannot be utilized to the same advantage in normal times. However, the lengthy duration of the war, and the mechanical experience they have gained, both in the operation of machines and the accurate manipulation of tools and gauges, may well fit many of them for a place in future mechanical activities.

The inability to distinguish a mechanic on his own "say so" is often an expensive experience for a factory superintendent. A try-out sometimes proves a complete failure, while a refusal to engage may be equally costly. The remuneration will be an additional inducement for many of these present shell workers to seek positions in the machine shops of the country. Many of those now working in munitions plants were formerly employed at much lower wages than those paid for machine operators in normal times, and from the knowledge picked up during their shell making "apprenticeship," they may imagine they are qualified for a machine shop position. Being deficient, however, in the elementary requirements of machine shop practice, and a general knowledge of the fundamental principles necessary for self-reliance, the average shell "mechanic" would probably "fall down" when given an unusual or complicated job. The cessation of shell manufacture will, therefore, place upon the market a very large number of men, the employment of whom may well prove a difficult post-war problem.

The General Market Condition and Tendency

THE situation in industrial circles has not as yet been materially affected by the definite action taken by Congress at Washington, although a more optimistic feeling has resulted. An element of uncertainty has been removed which alone will have a beneficial effect on business. This latest development in the International situation has not in the meantime affected prices of steel products, indications however, point to a continuance of the present upward movement. There has, however, been some talk of regulating prices of steel for the United States and Allied Governments. In what way this would affect the price to the ordinary consumer is problematical. The situation at the mills has improved considerably and production is steadily increasing. Raw materials are moving on the railways in better volume, but manufacturers are still being handicapped to some extent by delayed shipments. The railways are doing better than they were a short time back, but there is a lot of freight to move yet before conditions are normal. Hamilton foundry pig-iron is off the market again on account of the heavy demand for steel making grades. A price of $45 has been issued on Victoria pig-iron made at Port Colborne, Ont. Prices on most non-ferrous metals are unchanged this week, the market being dull and easy. The metal markets are dominated by the International situation and consumers are awaiting developments. The scrap metal market is quiet and quotations unchanged. The demand for steel and iron scrap is the principal feature of the market. The demand for machine tools continues light, but a number of important price advances have been made by builders in the United States.

Montreal, Que., April 9th, 1917.—The momentous step taken by the United States Government may or may not directly influence the duration of the war and the extent to which it will affect the general market conditions is as yet, problematical. That a very definite understanding will be arrived at between that country and the nations of the Entente Allies, is certain. One of the first considerations of the new relationship will be a complete readjustment of shipping regulations, to establish the highest co-operation, in the best interest of pushing the war to a successful and speedy termination. It is anticipated that similar action will be taken by steel makers as those announced some time ago by the copper producers in the matter of supplying material to the Government. The early future promises some eventful movements throughout industrial circles, both in the States and Canada.

Steel

With the crisis past, and the tension of many months removed, United States interests are now awaiting the decisive action of the Government in developing a plan of operations. Full co-operation is expected between the steel interests and the government; and it is certain that the requirements of the latter will have precedence over all other demands, and on a lower basis than the prevailing market. The entrance of America into the war, will however, not be the means of cutting off extensive supplies of materials to plants now working for the Allied Governments, as it is realized that the best interests of all lie in the furtherance of supplies for existing field forces. It is therefore more than probable that no anxiety will develop among those—steel users who are working on munitions, but it is anticipated that the tonnage now on order for home and export domestic use, may be diverted into other channels more closely connected with the prosecution of the war. Pressure on the plate mills will increase, following the recent declaration and delivery on ship, plates may be extended owing to the urgent needs of British contracts. The rising tide in pig iron would seem to predict higher levels on steel products, and neglecting the effect of the recent American declaration, the tendency is still upward. A favorable feature of the present situation, is the better facilities for handling material, owing to the increased car supply and improved railroad conditions. The early opening of navigation will assist in this connection. Billets and sheet bars are comparatively quiet, consumers being well supplied, and mills busily awaiting the policy of the government. Prices as high as 8c have been asked for tank plates, Pittsburg. The Pittsburg quotation on black sheets has been advanced to 6c, this being $10 higher than last week. Blue annealed sheets, have advanced $5, the nominal quotation being $5.50 per hundred. Local dealers expect an early revision of prices. Discounts are disappearing from cold rolled shafting price lists, the most recent advance being a reduction of 10 points, the present discount being about 5 per cent. off list. Heavy demand continues for wire products, while producers of wire rods are still unable to satisfy the trade requirements. Wrought iron pipe has again been advanced, the latest rise being $10 per ton. These advances are mostly due to the filled up condition of the mills. A practical famine exists in boiler tubes and higher levels are not unlikely. Conditions locally are unchanged but readjustment of prices are under consideration.

Metals

The week has been characterized by slight buying activity, the general disposition being to await further developments of the international situation. Copper has declined as a result of producers' action in regard to government requirements. Tin continues quiet with little trading and easier prices. Spelter and lead responded to increased traffic facilities, spot prices showing a decrease at New York. Antimony showed a decided upward tendency while aluminum grades covered quite a range. No changes are reported locally but some advances are looked for.

Copper.—Quiet prevails in the copper market and little business is being done. This is likely the result of the recent action of the States and nothing of importance is expected until the situation becomes more settled. London is firm while New York has fallen off ½ cent on lake and ¼ on electro. The local market is firm and unchanged; lake and electro are quoted at 39½ cents and castings at 38½ cents per pound.

Scrap

Although the week has been an eventful one politically, the general industrial conditions have not yet experienced any marked change, as a period of uncertainty still dominates the situation. New York prices on old copper are ½ cent higher, and old brass is slightly lower, but local quotations are unchanged on an uncertain market.

Toronto, Ont., April 10.—Events at Washington have occupied the centre of the stage this week, but the decision of Congress to enter the war did not have very much effect on business locally except that it created a more optimistic feeling. This development was more or less expected and consequently discounted. It is too early to determine precisely what effect this latest development in the international situation will have on business in Canada, but it is difficult to see how it can be anything but beneficial. It will bring the two countries into closer relationship and understanding, an important factor in business dealings during times of peace, and of great moral effect in war time.

Steel

No marked change in the situation in the steel trade in Canada has followed the decision of the United States' Congress to enter the war against Germany. The U. S. Government is understood to be making arrangements with the steel companies for fixing steel prices, which, it is believed, will be considerably lower than the current quotations. Until this question is settled, the market will be unsettled, for it remains to be seen what action, if any, the mills may take in regard to rearrangement of price shedules to domestic and foreign consumers. In the latter category would be included Canadian buyers. In any event, it is difficult to see how prices, particularly for steel for ordinary purposes, other than munitions, can do anything but go higher. The tendency at present is distinctly in an upward direction, and the increased pressure on the mills can hardly fail to force prices up. The continued increase in prices of pig iron is also an important factor in the situation, and is bound to have an important bearing on prices of steel products. The effect of developments in the United States market will be felt by Canadian consumers of steel imported from that country, and not to any appreciable extent by the Canadian steel companies, whose output is largely being taken care of by the Imperial Munitions Board. This feature has had the effect of steadying the trade, although prices have been advancing in line with the U. S. market.

Another sharp advance in wrought pipe of $6 per ton following a $4 advance last week makes a total advance of $10 in practically a week. The higher prices are attributed to shortage and high cost of raw material. The expected advance in rivets has materialized, boiler rivets being now quoted at $6.60 and structural at $6.50 per 100 lbs. base. Pressed steel spikes are also higher, being now quoted at $5.20 per 100 lbs. base. Plates and tubes are very firm at current quotations and higher prices are looked for in the near future. The demand for plates, principally from shipbuilders, continues enormously heavy. Sales of ship plates have been made at 8c mill, an extraordinarily high price, but likely to be eclipsed before long.

Prices of black sheets continue very firm, and a further advance appears to be likely at no distant date, affecting both black and blue annealed sheets. Although production has been materially increased, the mills are still behind on deliveries. Prices on galvanized sheets are also very firm, with a higher tendency.

The steel market in the United States is dominated by the international situation. The chief consideration for the time being is the extent of the Government's requirements of steel and the fixing of prices. It is understood that substantial concessions will be made by the steel companies to the Government from current prices, but what definite effect this arrangement will have on the market is at the present moment impossible to determine, except that prices are more likely to continue advancing than otherwise. A few price advances have been made during the week. Tank plates are now being quoted at 5.75c Pittsburgh, and Chicago warehouse price on steel bars is now 4.25c, and on structural shapes 4.50c.

Pig Iron

The pig iron market continues very firm, and prices are still on the up-grade. The Steel Company of Canada have turned their No. 2 furnace at Hamilton over to basic pig iron, and have withdrawn prices on foundry iron. Victoria foundry iron is now being quoted at a nominal price of $45 per ton. The situation at Buffalo is very tight owing to the sold-up condition of the furnaces and very low stocks. Producers are quoting $41 to $42 furnace on No. 1 foundry iron.

Scrap

Prices on scrap metals have a weak tendency except on steel scrap and machinery cast iron, which are in good demand. The high cost of pig iron has created an unusually heavy demand for cast iron scrap and caused an advance in price of this material. Steel turnings continue in good supply, with a fair demand. Scrap copper and brass are weaker and the market dull.

Machine Tools

Although the market is quiet, prospects are looking better for increased business. Some makers of 18-pdr. and 4.5-in. high explosive shells have recently purchased some machine tools to balance up their plant for increased production. It is reported that an American concern is anxious to locate a plant in this province and, if successful, a considerable quantity of machine tools will be required. An important development affecting the local market is a number of advances in prices of machine tools recently put in effect by some builders in the United States. The advances include the following tools:—Radial drills and shapers, 10 per cent.; upright drills and power presses, 5 per cent.; and engine lathes, 10 per cent. It is interesting to note that prices on radial drills are now approximately 90 per cent. higher than they were two years ago. Shapers are about 40 per cent., upright drills 50 per cent., power presses 20 per cent., and engine lathes 60 per cent. higher than they were two years ago.

Supplies

There are no important features to note in regard to machine shop supplies except that business continues very good and prices are holding firm.

Metals

The metal markets this week are generally dull and quiet. The markets are unsettled on account of the international situation, and consumers are inclined to hold back awaiting developments. The decision of the U. S. Congress to take an active participation in the war did not affect metal prices, as was anticipated in some quarters. Locally business continues very good at unchanged prices. The metal exchanges in London and New York were closed from Friday to Monday inclusive for the Easter holidays.

Copper.—Prices continue nominal and unchanged, but the market is unsettled, and there appears to be some doubt as to what may develop in regard to values. The recent low price for copper made to the U. S. Government by the producers has affected the market, and what will be the result on the price situation generally is difficult to determine. Local prices are unchanged, lake and electrolytic being quoted at 40c, and castings at 39c per pound.

Tin.—The market is very dull in New York, with very little business doing, due to the political situation. Prices advanced recently in London, but trading has been light for several days. Local price, 50c per pound.

Spelter.—The market is dull and easier. Consumers are awaiting developments in the zinc ore situation. Spelter is unchanged locally at 14c per pound.

Lead.—There is no change in the situation in regard to lead. Prices are being well maintained, there being no disposition to quote below the "Trust" price. Lead is unchanged at 12¼c per pound.

Antimony. — The market continues firm, and prices have an upward tendency. Local price nominal at 36c per pound.

Aluminum.—The demand for aluminum is at present light, and quotations are unchanged at 68c per pound.

OUR ORDERS FROM FOREIGN COUNTRIES GROW

LARGE purchases have been made by the Canadian Department of Trade and Commerce for some of the Allied Governments, according to the annual report of the department, just issued. The French Government late in October, 1914, expressed a desire to purchase blankets in Canada for the French soldiers. The Minister of Trade and Commerce, Ottawa, acting for the purchasing committee of the Cabinet, made the necessary arrangements to purchase the blankets. The Department of Militia and Defence supervised the inspection of the blankets, and the Department of Trade and Commerce made payment therefor on presentation of the necessary certificate of inspection. The order from the French Government was for 400,000 blankets to be delivered at the earliest possible date. Much difficulty was encountered in placing so large an order in Canada, as the Canadian factories were working at full capacity. Canadian factories were given orders to the limit of their capacity, but a portion of the order allotted to Canada had to be filled in the United States. Considerable trouble was experienced in obtaining sufficient ocean transportation from St. John, the port of shipment, but shipments were made as promptly as possible. Orders were placed for over 457,000 blankets, but the mills supplied 406,716 blankets, of a value of $1,613,000.

The South African Government early in March, 1915, cabled that they desired to purchase 35,000 bags of flour. The Department of Trade and Commerce was charged with the matter, and on March 6 called for tenders from the principal flour mill companies in Canada. A contract was entered into with one of the principal companies for the delivery of flour in New York for shipment to South Africa. The department also arranged for the inspection of the flour at the mill. The shipments were made from New York on March 30 and April 17. The total expenses in connection therewith amounted to $129,663.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Shirts and Blankets for Italy

In July, 1915, the attention of the Government was directed to the condition of the knit goods industry of Canada. It was pointed out that the mills producing underwear, sweater coats and socks were practically idle and the assistance of the Government was asked in securing orders from the allied governments for a portion of their military requirements. The Minister of Trade and Commerce took the matter up promptly and effectively. Orders were secured from the Italian purchasing commission for 600,000 undershirts and 100,000 blankets. The department undertook the inspection of the shirts and blankets which were sent from the mills to the Italian Government via New York. The department made payment to the mills on receipt of invoices covering the shirts and blankets, supported by certificates of inspectors and certificate of arrival in New York. Up to February 15, 1917, 101,974 blankets were shipped to Italy at a cost of $335,618, and up to the same date 1,909,624 shirts had also been sent to Italy at a cost of $1,946,492, a total of $2,280,110.

AMERICAN SHIPBUILDING

THE Shipping Board's program of building a fleet of 1,000 wooden ships of 3,000 or 3,600 tons each to meet the loss of tonnage by submarine warfare and thus help to defeat the German undersea campaign has been formally approved by President Wilson. The first ship will be ready within five months, and the board will call upon the Treasury for from $10,000,000 to $15,000,000 within the next few days. Fifty million dollars already has been authorized by Congress for the work of the board.

Chairman Denman announced that the board's plans have been virtually completed, and that the preliminaries to the construction of the big fleet were in full swing. Contracts have been let with the builders, arrangements have been virtually completed for the supply of standardized lumber parts, the labor problem has been settled, at least partially, and unless there is an unforeseen hitch, by October the shipyards on the Atlantic and Pacific will be turning out the new vessels at the rate of two or three a day to be leased to private shipping concerns.

The great fleet will fly the American flag, and each vessel sailing to the war zone will be armed. The program calls for the building of two hundred thousand tons of shipping monthly. The builders will be encouraged to complete the vessels speedily, and plans have been made to make partial payments on vessels, where necessary, from month to month. The present program calls for leasing the ships to private firms.

COMMERCIAL DEVELOPMENT OF TECHNICAL BUSINESSES

By Geo. H. Gibson.

THE application of science proceeds at an accelerated pace. The days have about gone by when one good idea would keep a family in business for several generations. No one dare rest content, for as Solomon reamarks, "Yet a little sleep, a little slumber, a little folding of the hands to sleep, so shall thy poverty come." Every manufacturer, and particularly manufacturers of engineering appliances and products, must maintain a constant output of improvements and new developments in order to protect their investment in plant, organization, and good-will, and, indeed, to stay in business. As has justly been said, the invention of a new machine or process—by some one else—may be as disastrous as a fire, and far more likely to occur.

Moreover, the more progressive, the more advanced, a concern is, the greater will be its volume of new developments and improvements. Inventions breed inventions. At the same time, the investment of time and money in research and development is a capital risk—that is, the preliminary investigation upon

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukbgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

which the design of improved apparatus is based and the provision of manufacturing equipment and organization for turning it out, must largely be paid for before the market for it can be developed. It is only by the prompt enlightenment of the prospective consumer—in other words, by educational advertising regarding the applications and advantages of the new article—that the loss of time and the waste which always intervene between the perfection of a device or process and its general use can be reduced.

The introduction of new things is a speculative venture which bars the timid —but for that very reason is highly profitable. Patents more or less effectively insure to the originator a safety zone, protecting him from competition for a limited period that he may have the opportunity to recover his great initial outlay. Advertising, however, is equally useful, since it can shorten the period of loss, conserving for profit-making a greater portion of the several years' monopoly conferred by the patent, and increasing the volume of profit. Advertising itself exerts an accelerating influence on technical development, for before advertising one should have something worth advertising. Much of the strategy in the competitive selling of engineering appliances consists in originating better methods or designs, or new and improved products.

A good example of the necessity of appreciating research on the part of the directors of industrial enterprises is supplied by the editor of *Engineering*, who relates that the firm of Simpson, Maule & Nicholson, in their day, leading manufacturing chemists in England, became millionaires largely through the fact that Nicholson was a very able chemist. When he retired, the firm ceased to develop. His successors employed several able chemists, but these had no control over the business policy and the end was disaster. At one time their leading chemist was the late Prof. Meldola. When he invented his blue, however, the firm refused to take it up, and he accordingly published an account of his discovery with the result that it founded the fortune of a leading German firm. The successor of Meldola was Prof. Green, who invented primulin, a dye of an entirely new type. This the firm refused to patent, and within a few weeks it was in consequence made in Germany, the whole advantage being lost to England.

Engineering products are purchased almost solely for their utilitarian value. Their usefulness can be weighed, measured or computed in some way, and they are usually purchased with much deliberation, for the reasoning faculties of the people who buy them have been emphasized by technical and business training.

The world is run largely on ideas; and the dissemination of ideas is the business of the advertising engineer.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Windsor, Ont.—Dodge Brothers, of Detroit, Mich., are making preparations for establishing a plant at Windsor, Ont., at a cost of $100,000.

London, Ont.—The Spramotor Co. proposes to establish a foundry and machine shop at St. Thomas, Ont., to cost $100,000. W. H. Heard is manager.

Montreal, Que.—The Riordon Pulp & Paper Co., contemplate developing water powers at Hawkesbury and Merritton, Ont., aggregating 30,000 h.p.

Bay Shore, N.S.—The C. P. R. will build an addition to its roundhouse at Bay Shore, and will also construct a 40,000-gallon water tank. E. N. Bender, Montreal, is purchasing agent.

Fergus, Ont.—Beatty Brothers are receiving bids for the erection, at London, Ont., of a brick and steel foundry, 140 x 160 ft., to cost $50,000, and a cupola, two storeys, 48 x 48 ft. Mr. Deacon is manager.

Niagara Falls, Ont.—Actual work has been started on the Chippewa-Queenston Power Canal. The construction of a double-track railway to carry material will soon begin now, and then by the fall excavation operations will commence in earnest.

Montreal, Que.—A company has been formed here to manufacture air craft at Laval de Montreal, north of the city. The company are negotiating for the Canadian rights of a new type of aeroplane and have manufacturing rights for a new type of engine.

Quebec, Que.—The Quebec Munitions Co., has secured premises on Dalhousie street in which to commence the manufacture of munitions, Ross sporting rifles and other articles that the company will have authority and facilities for manufacturing very shortly.

Walkerville, Ont. — The Chalmers Motor Co., will rebuild their factory which was recently destroyed by fire. Arrangements are being made by Harry S. Lee, general manager of the company to take over another manufacturing plant in Windsor of Walkerville and get into operation immediately. In the meantime the orders of the Canadian plant will be filled in the Detroit factory.

Waterloo, Que.—The Southern Canada Power Co. has been granted a ten-year exclusive franchise in the town of Waterloo, and street lighting contracts for the same period. The company has also taken over the Richmond light and power to the towns of Richmond, Melbourne, etc., and has also taken over the Cowansville Electric Co., supplying light and power to the towns of Cowansville and Sweetsburg.

Cobalt, Ont.—The McKinley-Darragh have commenced the erection of a new building to house a second flotation plant. The new mill will have a capacity of 200 tons per day, and the regrinding will be accomplished by a 4 x 8 Marathon mill, the first of its kind to be installed in the Cobalt camp. After regrinding the sands will be treated in the new Callow oil flotation plant. This new innovation will bring the flotation capacity of the McKinley-Darragh up to approximately 400 tons per day.

GENERAL

Listowel, Ont.—The Perfect Knit Mill Co., contemplate building a factory here to cost $25,000.

Gladstone, Man.—The plant of the Echo Milling Co., was destroyed by fire on April 1., Loss $115,000.

Montreal, Que.—The Clark Canning Co., will build an extension to their canning factory at Harrow, Ont.

Chatham, Ont.—C. & T. Hadley are the general contractors for the new factory which will be erected here for Libby McNeil & Libby of Chicago.

MUNICIPAL

Sherbrooke, Que.—The City Council are in the market for a portable air compressor.

Prince Rupert, B.C.—The City Council are considering the question of installing a cold storage plant to aid the fishing industry.

Sudbury, Ont.—The Town Council propose to spend $46,000 for a stand pipe and auxiliary water main, and $2,500 for alterations to the lake sewer pumping station.

Regina, Sask.—The City Council is receiving prices for one electric pump, capacity 3,000,000 gallons, and motor. Full particulars may be obtained from J. R. Ellis, city engineer.

Redcliffe, Alta. — The Town Council propose to lay about one mile of 10-in. steel or cast iron pipe, and instal extra pumping plant. Engineer, J. E. Askwith.

Hillsdale, Ont.—It is proposed to instal an electric lighting plant here. The equipment will consist of a gasoline engine and generator. Particulars from T. D. Robinson, township clerk, Moonstone, Ont.

Montreal, Que.—Controller Ross and Dr. Goucher of the City Health Department, will look into a project laid before the Board of Control by Henry F. Cook. Mr. Cook asks for permission to build an abattoir on Iberville street and to deal with all the city's garbage at a rendering plant outside the city, if the Board will give him six months notice. give him the bodies of all dead animals and pay the costs of conveying them and the garbage to the rendering plant.

ELECTRICAL

Aylmer, Ont.—At a meeting of the Town Council on April 2, a bylaw to borrow $29,000 for Hydro power by the issue of debentures was passed, $22,000 being the amount to be set apart for the remodelling of the electrical distribution system and $7,000 for the installation of an electrically-driven pump, a gasoline pump or an electrically-driven fire pump. A by-law will be submitted to the ratepayers on April 30.

TENDERS

Montreal, Que.—New tenders are being called for road flushing and sweeping machinery.

Drummondville, Que.—Tenders will be received until April 20 for drilling wells and supplying pumping equipment.

Yorkton, Sask.—Tenders will be received until April 30 for one 350-400 b.h.p., combined Diesel electric unit. Specifications may be obtained from F. J. Pilkington, Town Clerk.

Montreal South, Que.—Tenders will be called sometime in April, for a 30-h.p. motor-driven turbine pump and a 150-h.p. gasoline engine-driven turbine pump for fire purposes, etc. E. Drinkwater, St. Lambert, Que., is the engineer.

Edmonton, Alta.—Tenders will be received up to May 1st next, for the supply of automobile markers for the Province of Alberta, during the year 1918. Specifications may be obtained on application to the Deputy Provincial Secretary, Edmonton, Alta.

New Toronto, Ont.—Tenders will be received up to April 13, for gasoline engine and centrifugal pump, Venturi meter and a quantity of flanged pipe for pump house. Plans and specifications may be seen at the offices of the consulting engineers, James, Loudon & Hertzberg, Ltd., 36 Toronto St., Toronto.

Toronto, Ont.—Tenders will be received by Frank Barker, Engineer for the Township of York, up to April 14, for the supply and delivery of 24-inch stop valves and hydrants. Plans and specifications may be seen, and all necessary information obtained, at the office of the engineer, 57 Adelaide Street, East, Toronto.

Winnipeg, Man.—Tenders, addressed to the Chairman, Board of Control, will be received up to April 16, for the supply of labor and materials required in the erection of a 150 foot brick or concrete chimney for the Elmwood Incinerator. Plans, specification and form of tender may be obtained at the office of the City Engineer, 223 James Avenue.

Hamilton, Ont.—Tenders willl be received up to Wednesday, April 18, for supplying the City Corporation with 400 feet of ¾-inch chemical fire engine hose and with 1000 feet of 2½-inch cotton rubber-lined fire engine hose, according to specifications prepared by the Chief of the Fire Department, copies of which may be had on application at his office.

Winnipeg, Man.—Tenders addressed to the Commissioners of the Greater Winnipeg Water District will be received up to April 16, for the supply of miscellaneous bronze castings, brass piping, etc., which enter into the construction of a Venturi meter. Specifications and form of tender may be obtained at the offices of the district, 501 Tribune Building, Winnipeg.

Winnipeg, Man.—Tenders addressed to R. D. Waugh, Chairman of the Commissioners, Greater Winnipeg Water District, up to April 16, for the supply of approximately 12,000 feet of 48-inch and 1,300 feet of 60-inch cast iron pipes, together with numerous specials and gate valves. Specifications may be obtained upon application to the offices of the District, 501 Tribune Bldg., Winnipeg.

Winnipeg, Man.—Tenders, addressed to the chairman, Greater Winnipeg Water District Commission, at 501 Tribune Building, Winnipeg, will be received up to April 16, for the supply of one second-hand passenger coach, also one second-hand caboose, both standard gauge. Tenderers to supply own specifications. Further particulars on application to undersigned. R. D. Waugh, Chairman of Commissioners.

Ottawa, Ont.—Tenders will be received until April 21, for steam boilers and stokers required for the Central Heating Plant for the Parliament Buildings. All tenders to be based on the supplying and erecting of three water tube boilers, each having a rated capacity of 500 horse power, together with fittings and soot blowers. Each tender shall give separate quotations for supplying and erecting, in connection with boilers, three automatic stokers. One boiler and stoker shall be erected complete within five months after date of awarding contract and the other two shall be erected before January 1st, 1918. Plans, specifications and any other information required can be obtained at the office of the general contractor, P. Lyall & Sons Construction Co., Ltd., Ottawa.

PERSONAL

E. T. Austin has been appointed manager of the Belleville Waterworks Department in succession to J. W. Evans.

Thomas J. Gerry who for over twenty-five years was connected with the Dodge Manufacturing Co., Toronto, as traveller died at his home in Toronto recently.

George Bury vice-president of the C.P.R. has returned to London from Russia where he has been on an important business trip in the interests of the company.

W. G. Ross, chairman of the Harbor Commissioners of Montreal, went to New York recently to attend an executive meeting of the American Association of Port Authorities. Mr. Ross is president of the Association.

John J. Drummond, of Midland, Ont., died at the home of his brother, George E. Drummond, in Montreal, on Saturday, April 7. Mr. Drummond was long identified with the development of the iron and steel industry in Canada. In association with his brothers, George E. and the late T. J. Drummond, he established iron furnaces at Radnor, Quebec, and opened up large iron properties in the Maritime Provinces. He was president of the Zenith Machine Co., Midland, Ont. The deceased was born in the North of Ireland in 1856 and came to Canada at an early age.

BUILDING

Hamilton, Ont.—Plans are being prepared for an office building for the Canadian Westinghouse Co., on Sanford Ave.

Stratford, Ont.—Tenders for the additions for Brunswick and Shakespeare schools have been opened, and will be finally dealt with at a special meeting of the board to be held shortly. The committee has approved of a $7,722.50 tender for Brunswick school, but has taken no action on the Shakespeare tender. Both are higher than estimates.

TRADE GOSSIP

The Chevrolet Motor Co. of Canada has increased its capital stock to $1,500,000.

The Dominion Steel Foundry Co., and its subsidiary, the Hamilton Steel Wheel Co., are to be amalgamated and incorporated under the name of the Dominion Foundries & Steel Ltd. Both plants are located at Hamilton, Ont.

The Hall Engineering Works, with which is associated the Montreal Dry Dock Co., have started work on a new 50 by 150 feet plate and boiler shop at the plant of the latter. In addition to equipment already on hand, more new machinery will be required.

Big Demand for Ore Tonnage.—John Bell, general superintendent of the Playfair steamship interests at Fort William, Ont., after an extended trip to Buffalo, Cleveland and Chicago, reports there is a very heavy demand for tonnage for ore.

Copper Mine Reopened.—The copper mine at Red Head, Charlotte county, N.B., formerly operated by James McLean of Letete, has been reopened by a New York syndicate. A quantity of ore has been taken out and shipped to the United States for testing.

Ontario Hydro Surplus.—According to the report of the Hydro-Electric Power Commission for the year ending October 31, 1916, there was a surplus on the Niagara system of $351,833, applicable to sinking fund and depreciation reserve account, the receipts being $2,038,792 and the disbursements $1,686,958. The total operating capital is $9,522,995. On the Severn system there was a surplus of $40,256; the deficit on operation of the Eugenia system was $12,120, while the Wasdells system showed a surplus of $4,569.

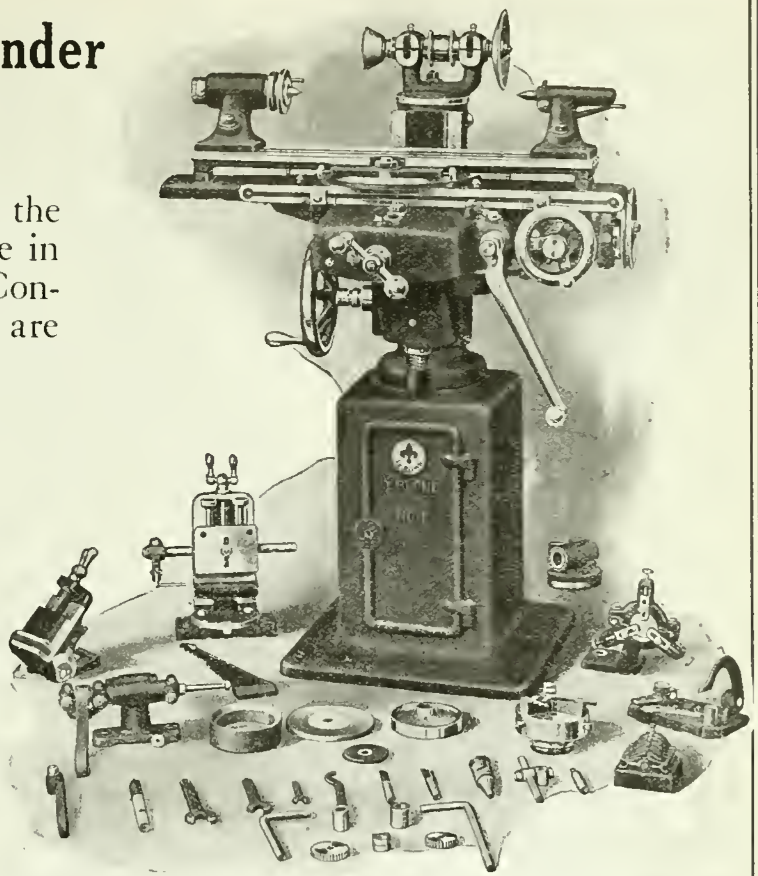
Making Valuation of Ross Rifle Plant. A valuation of the machinery and contents of the Ross Rifle Factory at Quebec, which the Dominion Government is expropriating, is being made by experts supplied by the Canadian Appraisal Co. and an accountant representing the Department of Militia and Defence. It is said the task will occupy the valuators for about two months. When it is completed, an offer will be made, it is understood, to the Ross Rifle Company on behalf of the Government. If that offer is not accepted recourse will be had to the Exchequer which will fix the price to be paid for the plant.

Opening of Navigation Forecast.—Predictions reaching the Marine Department, Ottawa are to the effect that navigation will not be open on Lake Superior until April 25. Lake Huron and Georgian Bay will be navigable somewhere about April 15. The St. Clair River, Lake St. Clair and Detroit River and the Western portion of Lake Erie are already clear of ice. At the eastern end of Lake Erie, however, there is still considerable ice, which makes it probable that navigation there will not begin until April 15 or 20. Similarly the western end of Lake Ontario is free of ice and the eastern end is not. Hence the prospect is that navigation there will not be open until April 15 or 20.

The Prest-O-Lite Co., Inc., manufacturers of oxy-actylene welding and cutting outfits, storage batteries, etc., have just let a contract for the erection of a four storey building in Toronto which will be used for the manufacture of electric storage batteries and accumulators, etc., with 35,000 sq. ft. of floor space. Construction will be commenced at once of an actylene gas plant at Shawinigan Falls, Que., while facilities at Merriton, Ont., will be considerably enlarged. Warehouses and show rooms will be opened in Montreal for both storage batteries and gas appliances. R. H. Combs Canadian general manager was, until recently, vice-president of the Society of Automobile Engineers.

British Embargo Lists Changes.—The British Government has prohibited the exportation of the following articles to all destinations. Anchors and chain cables, binnacles, leather boots and shoes with soles or uppers, lead compounds and mixtures containing them; ships' compasses and component parts; leather; lead, lead alloys and manufacturers of lead or alloys; nautical instruments;

The LeBlond Tool and Cutter Grinder



Try this Grinder—

It has been specially designed for the tool room and is perfectly at home in every department of cutting where Convenience, Precision and Production are essential.

It has numerous features which you need—Catalog—free on request—will tell you all about them.

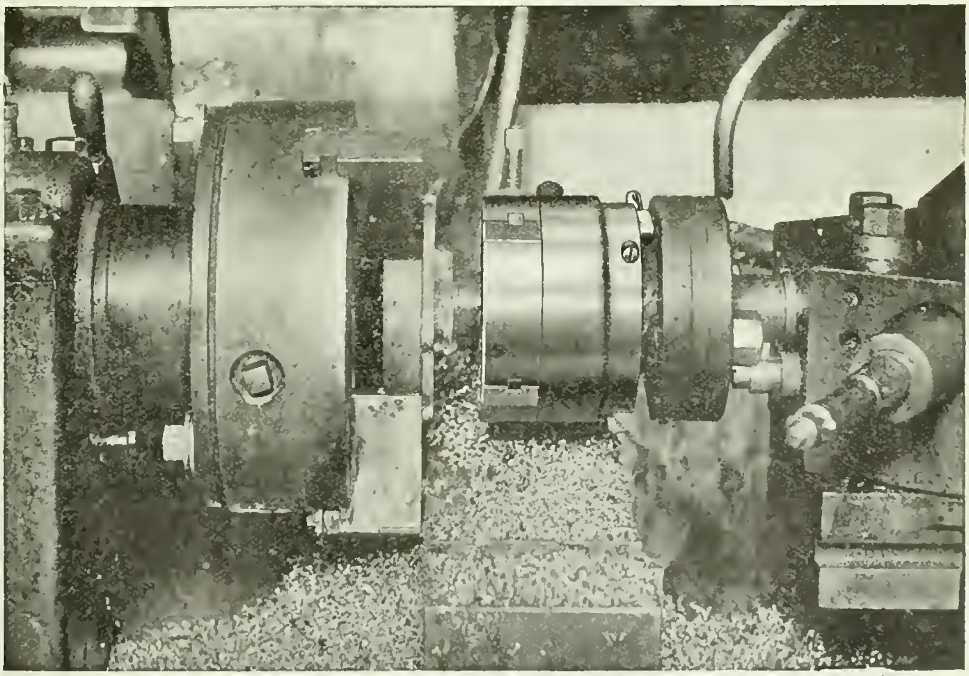
Shipment from TORONTO STOCK IMMEDIATELY.

THE A. R. WILLIAMS MACHINERY CO., Ltd.

64 Front St. West - TORONTO, ONT.

ST. JOHN, N.B. WINNIPEG VANCOUVER

"If It's Machinery, Write Williams."



The limits on this job are very close, but a Geometric Self-Opening Die Head finishes the threads so that they pass rigid inspection.

The part is a manganese bronze pump body, made by the Superior Machine & Engineering Co., on a Warner & Swasey Screw Machine.

Have you a Geometric on your Screw Machine or Turret Lathe? Send us your specifications and get our quotation.

THE GEOMETRIC TOOL CO., New Haven, Conn., U.S.A.

Canadian Agents:

Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg, St. John, N.B.

bootmaking machine needles; rattans; ship engines and their component parts, including Diesel and other internal combustion engines for marine propulsion; iron and steel castings and forgings for ships' hulls and machinery; machinery for steamships and component parts; sectional materials for shipbuilding; ships' auxiliary machinery; ships' telegraphs and component parts; steering gear and component parts; tanning extracts and substances; winches, windlasses.

Big Freighter Launched. — Last Thursday at 1.30 p.m., in the presence of a large number of spectators, the bulk freighter Westmount was successfully launched at the yard of the Collingwood Shipbuilding Co., Collingwood, Ont. The christening ceremony was gracefully performed by Mrs. L. L. Henderson, wife of the president of the Montreal Transportation Co., for which the new steamer is built. The Westmount is one of the largest boats on inland waters. Her dimensions are: Length 550 feet; breadth, 58 feet, and depth 31 feet, with a carrying capacity of 11,000 tons. Her engines are capable of developing 2,400 horse-power, and will drive the steamer thirteen miles per hour loaded. The steamer is modern in every way, and embodies many new features to facilitate loading and unloading operations. There are sixteen hatches, with 24-feet centres, and the large holds are divided into 24 compartments. The Westmount will go into commission immediately upon the opening of navigation.

MARINE

Sault Ste. Marie, Ont. — Navigation will open about April 20 if reports reaching the Soo are authentic. Ice-crushers will be used to force an opening in Mud Lake, St. Mary's River and Whitefish Bay. Unless this is done ice will hold up lake traffic until May 1.

Must Install Water Purifiers on Lake Boats.—Before the opening of navigation vessel owners of the Great Lakes must spend approximately $300,000 for the installation of new culinary and drinking water purifiers on all boats engaged in interstate traffic. The order applies to all vessels belonging to Canadian steamship companies plying on the Great Lakes. The order requiring installation of pure water systems was issued some time ago by Dr. J. O. Cobb, Chicago, surgeon of the sanitary district comprising the Great Lakes. The water must be treated by an approved method, and that the piping system on all vessels must be so arranged that no connection can be made between the drinking water system and any other water system.

WOODWORKING

Montreal, Que.—The Montreal Box Board Co., will build an extension to their factory.

Quebec, Que.—The box factory of the Canadian Butter Box Co., at D'Israeli, Que., near Sherbrooke, was burned to the ground on April 4.

CONTRACTS

Port Arthur. — J. F. Hewitson has been awarded the contract for the construction of buildings for the Port Arthur Pulp and Paper Co.'s plant here to the extent of $350,000.

INCORPORATIONS

Lion Locks, Ltd., has been incorporated at Ottawa, with a capital of $50,000, to manufacture builders' hardware, locks and locking devices of all kinds. The head office is at Toronto and the incorporators are: Aubrey T. Maher, John B. O'Brien and Thomas S. H. Gales, all of Toronto.

J. R. Cameron, Ltd., has been incorporated at Ottawa, with a capital of $50,000, to take over the business carried on by J. R. Cameron, stove and furnace manufacturer, of Ottawa. The incorporators are: Joseph R. Cameron, R. Edward Byrne, and John S. Nicholson, all of Ottawa.

Huot Rifle Automatic Attachment Co., has been incorporated at Ottawa with a capital of $500,000 to manufacture rifles and rifle parts. The head office of the company is at Montreal and the incorporators are Joseph A. Huot, S. Edmond Desmarais and Joseph A. Belair all of Richmond, Que.

The Omega Machinery Co., has been incorporated at Ottawa with a capital of $45,000 to manufacture water towers, wind-mills, pumps and all kinds of machinery at St. Hyacinthe, Que. The incorporators are Ovide Brouillard, Etienne H. Solis of Montreal and Emile Ponton of St. Hyacinthe.

The Collier Oil Co. has been incorporated at Ottawa, with a capital of $2,000,000, to acquire oil lands and to construct and operate refineries at Calgary, Alta. The head office is at Toronto, and the incorporators are: Henry P. O. Savary, Lloyd H. Fenerty, and Henry A. Chadwick, all of Calgary.

P-K Worsted Spinning Mills Ltd., has been incorporated at Toronto with a capital of $50,000 to build and operate spinning mills and dye houses as Listowel, Ont., Provisional directors are Frank J. Barber of Georgetown, Ont., and Max Becker and John H. Bender of Listowel, Ont.

The Paper & Hardware Products, Ltd., has been incorporated at Ottawa, with a capital of $49,000, to manufacture paper, felt, straw board and pulp products of all kinds. The head office is at Montreal, and the incorporators are: W. A. Lyons, Henri Larin and Patrick A. Donnelly, all of Montreal.

CATALOGUES

Electric Drills.—Circular Y is being distributed to the trade by the Independent Pneumatic Tool Co., Chicago, Ill., to feature the "Thor" universal electric drills. The circular illustrates a number of different types and contains specifications covering the various sizes.

The Watters' Bucket for use in foundries is described in catalogue 126 being distributed by the Whiting Foundry Equipment Co., Harvey Ill. The advantages of the Watters' bucket and its construction and operation are dealt with while several views of installations show the scope of service of the bucket.

Taylor Power Dump.—Catalogue issued by the American Engineering Co., Philadelphia, Pa., describing the Taylor power dump for use in conjunction with the Taylor mechanical stoker. The construction of this power dump and results accomplished by it are described while the method of operation is graphically explained by means of a number of illustrations.

The Standard Mfg. Co., Bridgeport, Conn., have issued a series of bulletins 202, 203, 212, 217, 219, 220, 221, 232, 233, 234, 235, 236, 237 bound in an attractive loose leaf folder illustrating and describing an interesting line of machine tools including gear cutting, automatic milling, drilling and riveting machines, etc., excellent half tones show the general arrangement of each type of machine while a specification is included together with descriptive matter covering the principal features.

Standard-Unit Construction for Steel Framed Structures.—F. Braby & Co., Glasgow, Scotland, have recently issued an interesting catalogue bearing the above title and illustrating the Reid patent unit system for the construction of steel buildings and structures of every description. The catalogue features a new system of quick fabrication and erection of steel structures. The catalogue contains a full description of the system and also a large number of diagrams showing various designs of steel work for factories, hangers and aeroplane sheds, etc. The concluding pages contain considerable useful technical data covering the properties and safe strengths, etc., of the standard units and bars, abridged list of spans and heights of building obtainable, and particulars of Braby's corrugated sheeting.

BOOK REVIEW

Canadian Woods for Structural Timbers.—The Department of the Interior, Forestry Branch, Ottawa, have published Bulletin No. 59, bearing the above title. The idea in publishing this bulletin was to offset an erroneous belief held by many Canadians that imported lumber is superior to the Canadian product. The Forest Products Laboratories of Canada, under the Forestry Branch of the Department of the Interior, have been investigating this question, and have found that some of our Canadian timbers are superior to those imported and just as cheap, if not cheaper. The results of this investigation are set forth in this bulletin, which also contains a number of interesting half-tones showing Canadian lumber being utilized for a variety of structural purposes. Lumbermen, builders, manufacturers, or others interested who have not yet received a copy may obtain one free on application to the Director of Forestry, Ottawa.

HIGHER COAL COMING.

The Coal Trade Journal says that the anthracite situation is growing very strenuous. It is said that the production of anthracite this year will hardly equal the consumption, and a shortage of cars is making it difficult to get coal into the New York market. The labor supply limits the production of coal, and with high wages in all fields labor is taking matters easily. Within the week there has been a considerable advance in the price of anthracite, and the retailer who is not forearmed with contracts to insure him a regular supply to take care of his customers, faces a hard winter. Some of the independent producers, finding an extra demand upon them, have been putting the price up day by day until premiums amounting to $1 a ton above the supposedly regular schedule have been paid. This is taken to mean that there must be an advance in the retail price, for the margin allowed the retailer is not sufficient to permit him to take up the advance in the wholesale price, even though premium coal is but one-fourth of his tonnage.

TUNGSTEN IN PORTUGAL

SOME very rich deposits of tungsten occur, it is said, in Portugal in the form of wolframite, accompanied by scheelite, and also, frequently, by cassiterite (binoxide of tin). The three principal deposits are the proptrty of independent companies, the first, a French concern, exporting its whole output to France: the second, an English company, exporting to England; and the third, which is operated exclusively by Portuguese capital. The daily output of the first two averages about one ton of wolframite each, containing 60% of tungsten trioxide: the output of the other concern is somewhat less. In addition, there are numerous smaller deposits, but the output of these is not known. In 1914 the exports of tungsten ore from Portugal amounted to 1,700 tons. No figures, however, are available as to the quantity produced. At present the exportation is made under the intervention of France and Great Britain, which countries absorb the greater part of the total shipments. A small quantity is exported to the United Staes.

MUNITIONS WORK IN SIGHT

FIRMS engaged in the manufacture of munitions in Canada will, on the basis of present orders, be kept busy up to June 30, 1917. Orders placed with some manufacturers expire on December 31, and with others on March 31. When these dates arrive, the performance made in delivery will be an important factor in deciding as to the extent of renewal orders. The Imperial Munitions Board states that all necessary raw materials to maintain the deliveries required are contracted for well ahead, and particular mention is made of the very favorable position in respect to steel supply. No uneasiness is caused by the reported shortage in the States, because of the purchases of steel made by the board last spring and summer.

The policy adopted some time ago, whereby Canadian manufacturers would supply fuses, primers, brass discs, cartridge cases and the many smaller components, is now well established, and supplies of this nature which came from the States in large quantities in the past, will to a very great extent be available in Canada. Canadian manufacturers are bending their best energies to enable the board to carry out its programme.

TECHNICAL MEN GIVE AID

THE Joint Committee of Technical Organizations, under the chairmanship of Alfred Burton, met in the Mining Building of the Toronto University group on March 30, to discuss and adopt the first annual report of the organization and to hear addresses by E. P. Mathewson, of Toronto; R. A. Ross, of Montreal; John Murphy, of Ottawa, and Captain A. J. Matheson, of Toronto. J. Murray Clark and W. A. Carlysle also spoke.

The chairman in opening referred briefly to the aims and objects of the committee which was formed last December, and is composed of one representative from each of the various technical and scientific institutions, societies and associations of Ontario. "The immediate aim," said Mr. Burton, "shall be to evolve a plan whereby such of our members as are unable to go to the front may be used for war purposes at home in such a manner as their special technical training may make them most valuable." He then proceeded to outline some of the work already accomplished by the committee, which, within three months, has already made many practical contributions towards the national efficiency for the prosecution of the war.

MISCELLANEOUS

Steel and Malleable Iron Castings.—The choice between steel and malleable iron castings is dictated by their respective properties, partly by price, and partly by the limitations of the processes by which malleable iron is made. As pointed out in a paper read before the International Engineering Congress, steel is, in its nature, a more homogeneous metal, and, therefore, tougher and stronger than malleable iron. Moreover, castings of malleable iron are somewhat prone to actual porosity or sponginess at the centre, especially in certain portions of irregular castings, so that for this reason also a steel casting is stronger and more reliable. Finally malleable iron can be made only into castings of quite light sections, whereas there is almost no limit to the size and weight of steel castings that can be produced. For uses where only a fair amount of strength and toughness is necessary, the castings being therefore of light section, it often pays to have them malleable, because they are cheaper than steel.

Friction Clutch Ring Tests.—In a recent issue of Alfred Herbert's Monthly Review an experiment is described which was made for the purpose of testing various designs of friction rings for use in the friction clutches of lathes. The ring being tested was held by hooks and opened by lifting up by a crane or lifting blocks, the stress being measured by a portable weighing apparatus. The expansion of the ring under different loads was measured by dividers set to centre dots in the same way as the expansion of a tensile test specimen is measured. By this means it was possible to obtain for each ring a record of the different expansions under various loads, which could be plotted in the form of a stress-strain diagram, and records were also obtained of the final breaking load and of the maximum expansion before breaking. By testing a number of rings of different material and of different design and proportions under these conditions considerable improvement has been made in the design of the friction clutches.

Concerning Twist Drills.—It seems incredible, says a writer in Alfred Herbert's Monthly Review, that no twist drill maker sends his product out correctly ground ready for use. Every drill maker claims some good point or other for his tools. Many or all of them have spent thousands of pounds experimenting with various shapes of flutes, angles of spiral, thickness of web, and so forth; further, thousands of pounds have been laid out on plant, tools and equipment, yet the one part of a drill that counts, perhaps, more than any other—the cutting edge—receives little or no attention. Why this should be probably no one can tell. It seems to the writer that the first drill maker who advertises the fact that his drills are ground correctly, ready for immediate use, will reap inestimable advantages in the way of largely increased sales. We believe that, if the writer is not misinformed, he has greatly overstated his case.—Ed.

FOR SALE — AT A BARGAIN — 1—1¼" style D geometric die head, with extra dies. White Machine Works, Windsor, Ont. c16m

GAP LATHE, 28 x 42 x 16 FT. BED, FOR sale, cheap; also emery wheel stand, power hack saw. Guarantee Motor Co., Hamilton, Ont. (tf)

FOR IMMEDIATE SALE THE FOLLOWing West Tire Setter Company banding presses: 1—9.2"; 1—6"; 1—3¼". All in first-class condition. Each been in use two months. The Elyria Machine Co., Elyria, Ohio. c15m

FOR SALE—ONE 450 H.P. THOMPSON & Williams condensing engine. Will sell cheap. Engine is in first-class repair and will give every satisfaction. Apply J. A. Marven, Limited, Moncton, N.B. tcfm

ONE No. 2 WHITING CUPOLA, 36" SHELL capacity, one to two tons per hour. In perfect condition, used only for two heats. Address Purchasing Agent, Canadian Ingersoll-Rand Co., Ltd., Sherbrooke, Que. etmf

2 CAN. GEN. 2 H.P., 1,200 R.P.M., 440-VOLT, 3-phase, 60-cycle induction motors, complete with pulley and slide base, $85.00 each. 1—1 H.P. ditto, $70.00. 1—Canadian Ingersoll-Rand air compressor, having displacement of 64 cubic feet per minute when running at 250 R.P.M. At 100 lbs. pressure it will require 11 H.P. $340.00. The Perfection Stove Company, Ltd., Sarnia, Ont. c15m

FOR SALE — TWELVE PRACTICALLY new No. 7-C Racine Heavy Duty High Speed Hack Saw Machines. Suitable for all Cutting purposes. Immediate delivery. For Price and further information address The Peck Rolling Mills, Limited, Montreal. c14m

ONE LATHE 16" x 4½' back geared. Built by P. P. Silk Machine & Tool Co., Cincinnati, Ohio. One lathe 18" x 3', back geared. Built by the Bradford Mill Co., Cincinnati, Ohio. Four Murchey Collapsible Dies. Capacity 1½" to 2½". Box 272, Canadian Machinery. ctmf

WE OFFER THE FOLLOWING MACHINery and tools at exceptionally low prices: 1—Heavy Duty Rockford Drill, 24", suitable for heavy work, in use only two months. 4—Jones & Lamson Turret Lathes, Bar machines, size 2 x 24; price $200.00 to $250.00 each. 2—Jones & Lamson Turret Lathes, Chucking Machines, size 2 x 24; price $200.00 each. 1—Small Turret Lathe, 1¾ hole in spindle, 1¼ hole in turret head. 1—Two-spindle Sensitive Drill, $100.00. 2—Holden-Morgan Thread Millers, slightly used on 4.5 shells. 4—Bertram Internal Thread Millers. 2—No. 9 Hartness Dies, capacity range 1¾ to 3" dia. 4—12" Whiton Universal Scroll Heavy Duty Chucks, 3-jaw. 1—10" Skinner Universal Chuck, 3-jaw. 1—10 x 12 35 H.P. Robb Horizontal Steam Engine, in first-class condition. Apply Steel Furnishing Company, Limited, New Glasgow, N.S. Cow17

SPECIAL MACHINERY

MANUFACTURERS — WE CAN UNDERtake work to any specification—munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

O. E. WOODS—HEAVY, LIGHT AND GENeral machine work. We are prepared to make to specifications and drawings, special machinery, punches and dies, jigs, fixtures and general tools. Prices reasonable. Prompt attention. Phone Gerrard 960. Address 754 Broadview Ave., Toronto, Ont.

Do you read these pages?

Of course you do. Then isn't it safe to assume that the majority of our readers do? When we get a reply to an ad from a firm like the National Cash Register Company one mail, and another from a machine tool salesman the next, and others from men in all positions, it would appear that these ads. are pretty closely followed.

If you have any proposition likely to interest our readers it will pay you to tell them about it here.

SITUATIONS WANTED

SUPERINTENDENT—PRACTICAL MECHanical man with 12 years' experience, last two years superintendent of shells, is open for a proposition. Box 289, Canadian Machinery. (c16m)

SUPERINTENDENT OR WORKS MANager of large metal working plant desires change. Broad gauge man of modern methods and a producer of results. Over 20 years' experience at handling large forces of workmen in manufacture of high quality and interchangeable goods of brass, iron and steel, special tools, dies, machinery, etc. Includes brass works, machine shop, punching and stamping and fine brass work, taking entire control of plant. English-American descent. Box 280, Canadian Machinery. c15m

SITUATIONS VACANT

A GENERAL SALESMAN TO HANDLE our general lines in part of Ontario. Apply Box 290, Canadian Machinery. C16M

YOUNG MAN WITH GENERAL KNOWLedge, to take charge of our sample floor. Apply Box 291, Canadian Machinery. C16M

WANTED—MACHINERY SALESMAN TO handle Toronto and Western Ontario. Apply, giving experience to Box 285 Canadian Machinery. c14m

MECHANICAL ENGINEER WANTED — first-class opportunity for the right party. Must be energetic, ambitious, sober and have some knowledge of French. Apply Box 286, Canadian Machinery. temf

PRODUCTION ENGINEER WANTED TO take charge of cost reduction work in Canadian shop manufacturing air compressors, rock drills and other lines. State age, experience and salary expected. Box 292, Canadian Machinery. C16M

MAN ABOUT 30, WITH ENGINEERING and commercial training, experienced in mine and smelter requirements, including structural and cast steel work. A man with office experience and capable of soliciting business preferable. Box 283, Canadian Machinery. c13m

EXPERIENCED TOOL MAKERS, SCREW machine hands and general mechanics wanted at once for new, well lighted plant (not munitions), situated just outside of Toronto; highest union wages and steady work for good men. Mention this paper. Canada Cycle and Motor Company, Limited, Weston, Ont. c13m

A GOOD SALES ENGINEER TO OPEN office to sell Moline Heat in Canadian territory. Must be a good salesman, having had a general heating and ventilating experience. Must give good references. We have a fine proposition for the right man. Address, Moline Heat, Moline, Ill. ctmf

Tool Holder and Cutting Tool Application Data--I.

By F. Scriber

The approaching return to broader and more general lines of manufacture render a study of tool-holders very timely. While the welded tip has found considerable application under recent conditions of heavy duty and unskilled operation, the obvious advantages of well designed tool-holders are such as to insure a continuance of their use, more especially where variety of work offers increased efficiency opportunities for well assorted equipment.

A QUESTION of vital importance with the ever-increasing cost of high-speed tool steel is the matter of the tool detail to be employed in the cutting of various metals. This item of machine up-keep is part of the daily shop maintenance, and cannot be entirely eliminated, but by careful planning it may be reduced to an absolute minimum. With this object in view, the tendency in late years has been to make the actual cutting tools in the form of an inserted blade which, when mounted in a suitable holder, is stiff; this permits of using most all of the tool and, in consequence, there is very little waste.

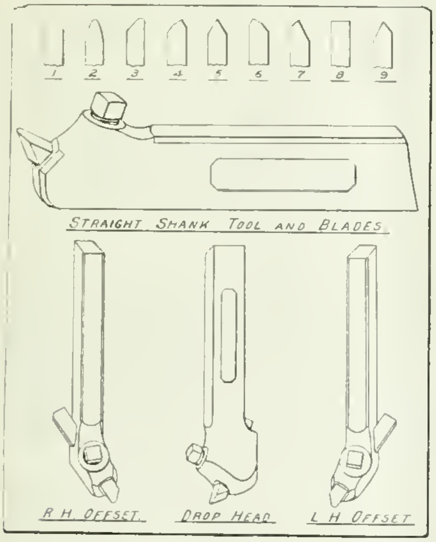

FIG. 1.

The practical limitations of these tools are quite generally understood, but many manufacturers who have had experience with them in the early stages of their development have built up objections which have tended to keep them from reaping many of the advantages which these tools surely possess. A tool-holder properly designed is rugged enough to withstand ordinary shop usage except under especially heavy cuts, and, by its use, a large part of the high-speed steel cost is got rid of. In addition to this, a good deal of "blacksmithing" is done away with; the inserted blades are usually easier to grind, as in most types of holders the cutters are held with the proper rake and clearances, and, consequently, this need not be considered when grinding the blades. The accompanying illustrations show a collection of tool-holders which are practical and well adapted for the work that they are intended to perform. Quite a number of the holders described are standard tools, which can be purchased in the market and these are, of course, tools of proven ability.

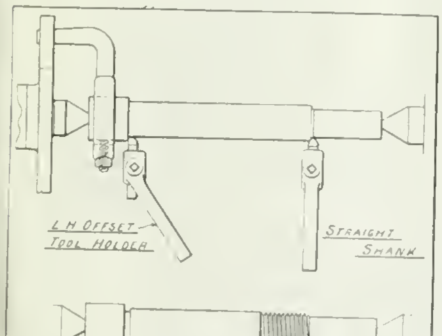

FIG. 2.

Referring to Fig. 1, this illustration shows an Armstrong tool-holder suitable for lathe work and planing. Cut shows a straight shank tool-holder, and the lower views show a right-hand offset, a left-hand offset and a drop head tool-holder, while the view at top of the illustration shows a number of cutters which may be held in these holders. From this collection it is possible for one to pick out cutters which are suitable to quite a variety of work on which one-piece form tools are extensively employed. From a study of these holders it is obvious that there are three common positions in which the cutters are set—at right angles to the work, those set to the left of this position, and those that set to the right.

Referring to Fig. 2, the upper view shows a left-hand-offset tool at work turning a piece of round stock in a lathe; a straight shank tool-holder working under the same conditions is also shown. In the lower view of this same illustration, a straight shank cutting-off tool is shown at the left, being used for necking a shoulder, and, in the lower view at the right, a straight shank threading tool is shown in operation. These two latter tools are shown more complete in Fig. 3. The upper view there shows the cutting-off tool, while the lower view shows the threading tool; the illustration in the middle shows a standard type of boring tool. All of the foregoing tools hold cutters, which are simple to make, are rigidly held in position, easily replaceable, and can be used under quite a variety of conditions while providing for the minimum waste of expensive material.

One-piece tools, of course, are quite indispensable for some classes of work, such as getting into corners, as they are compact, and consequently many attempts have been made to duplicate one-piece tools in simplicity, while reducing their cost. Examples of the general trend of this practice are shown in Fig. 4, the high speed portion of the tools being shown in section. The main portion of the holder or shank is made of machinery steel, while the various types, namely, Broad Nose, Round Nose, Diamond Point, and Side Tool, are welded to the shank, thus providing what is prac-

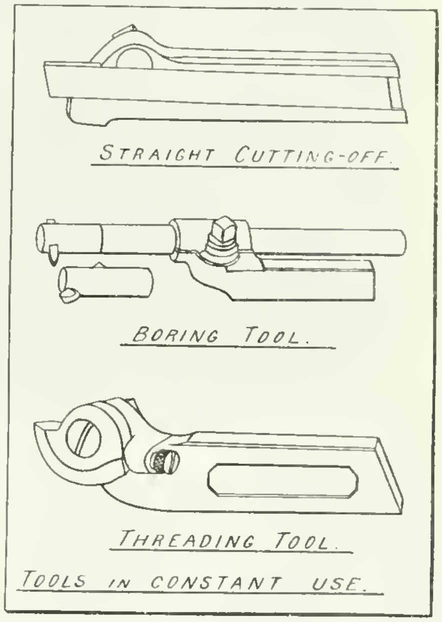

FIG. 3.

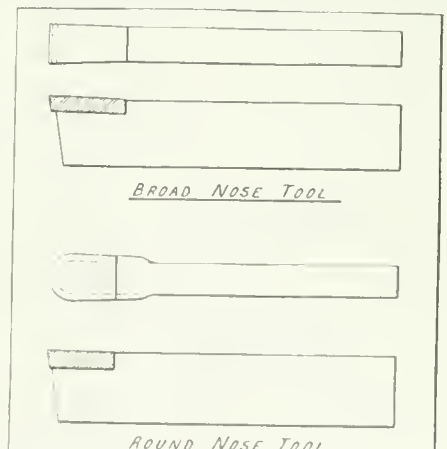

FIG. 4.

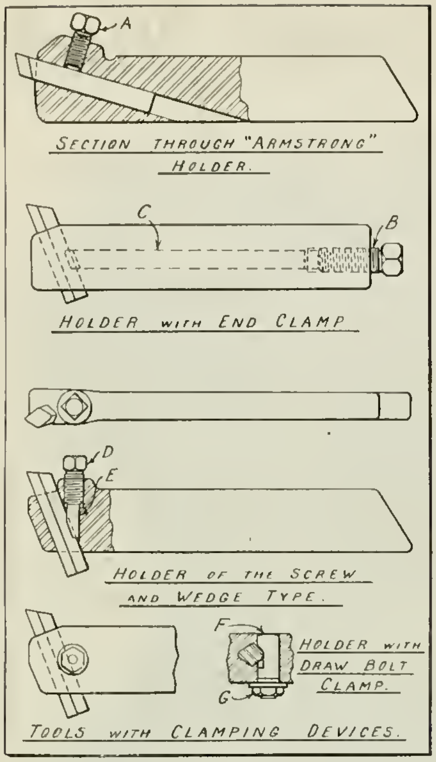

FIG. 5.

tically a one-piece tool combining the advantages of a high-speed cutting tool, with, at the same time, the compactness of a one-piece tool.

Returning again to the subject of inserted tool-holders, Fig. 5 shows a section through an Armstrong holder. The cutter in this tool is inserted on an angle to give the correct cutting rake, and is clamped by the screw A. The second view in this illustration shows a cutter which is clamped by a screw in the holder B, this screw being made to bind the cutter by means of the shoe C. The third view from the top illustrates a tool-holder, which has the cutter set in practically the same as the above, but clamped by means of the screw D, which forces the wedge E against the cutter, thus binding it.

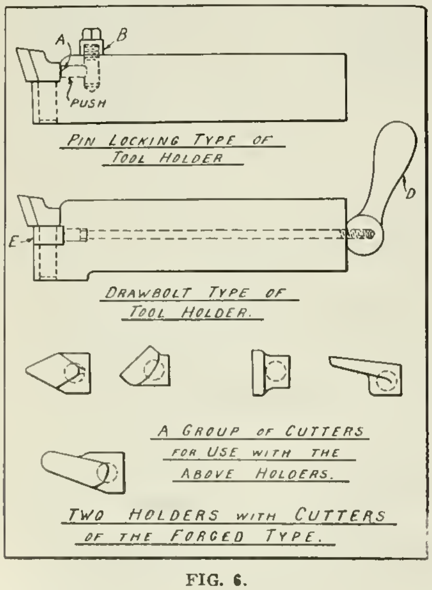

FIG. 6.

Referring to the lower view, the cutter is clamped by means of the familiar draw-bolt construction F, the bolt being cut out to clamp against one side of the cutter when the nut G is tightened. Other tool-holders which work on this principle lock the cutter by means of bushings, while still other holders clamp the blade by having the holder split and using a binding screw. It will be quite unnecessary to show all of the constructions which are found suitable for this purpose, illustration and description of the general principles involved being sufficient for our present purpose.

While most tool-holders are constructed with the idea of using blade stock of standard shapes, in recent years, owing to the fact that there are quite a number of odd shapes of steel being placed on the market which can be very conveniently held in tool-holders, this condition has been taken advantage of in a number of instances and, therefore, we find numerous tool-holders made to grip special shaped stock.

In other types of holders, the makers have gone into the subject still further, and have made the tool points or cutters special drop forgings adaptable to special holders only. Two holders based on this plan are illustrated in Fig 6, the upper one being a holder which has the point locked by a pin; this pin clamps at the back side of the cutter A when the screw B is tightened. The other holder illustrated has a draw bolt C running through it, which is tightened by the handle D at the end of the holder, and in the latter the cutter is bound on the shank E. A group of cutters or points, which may be used for a variety of work, and are held in these holders, are shown below in this illustration.

The tool-holders shown in Fig. 7 are somewhat different from the foregoing, inasmuch as the one in the upper view shows a cutter which is bound by a tapered wedge A. This cutter B has teeth cut in it to engage with the teeth in the wedge and, of course, the heavier the cut the tighter the wedge will grip, as the wedge is forced down in the holder by the cutting action as the blade "takes the cut." Care must be taken in using a tool of this type to have the wedge securely lock the cutter before starting to machine the work. The lower views on this illustration show a tool with an adjusting screw in back of the cutter; this screw permits of fine adjustments being made, and the screw C binds the cutter in the same manner as in some of the tools previously described. Adjusting screws are by no means confined to this particular type of tool, nor is it necessary to apply them in this particular manner, but they are employed in quite a variety of ways by different designers.

Reference was made at the beginning of this article to the fact that the blades were usually held at right angles to the work, or to the right or left of this position, but, in Fig. 8, we have a holder where all of these positions are obtained in one tool. The manner of accomplish-

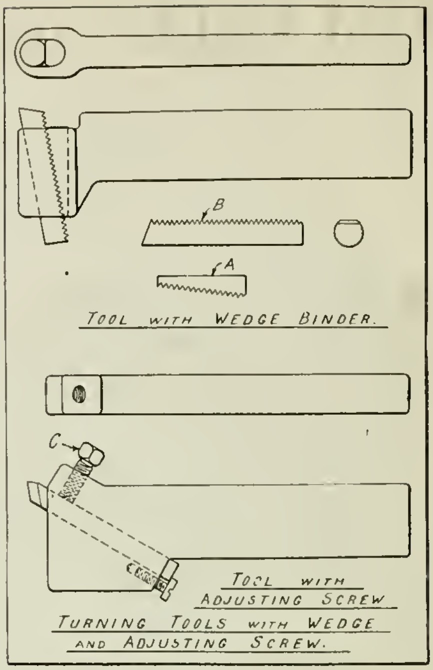

FIG. 7.

ing this is obvious, as there are three slots cut in the holder, and the cutter may be presented to the work from the slot which is most convenient. The cutter in this holder is clamped in any position by means of the screw A, which bears on the cutter at the intersection of the slots.

A tool-holder which contains two cutters is shown at work in the lower view of Fig. 8. The cutter B is of round nose type and the cutter C is a necking tool. These cutters are clamped by independent screws D and E in any convenient manner, the particular type here shown being the familiar set screw method of clamping.

In the succeeding articles of this series the subject will be enlarged upon, so as to take care of cutting-off tools, threading tools and boring tools as inserted blades in tool-holders.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

SPECIAL DESIGN THREAD MILLING MACHINE

By R. Hamilton.

THE specifications requirements in connection with the appearance and accuracy of the thread portions of the various types of shell, have been the means of developing many special attachments and machines for satisfactory accomplishment. Collapsible taps have been, and still are, largely used for the accomplishment of this operation, but the hobbing process has made remarkable progress since the inception of the shell industry. Many makes of thread millers have been placed on the market, but the magnitude of the munitions industry, and the inability of the many firms to secure the desired equipment in a special time, has resulted in a large number of plants solving this problem on their own behalf, that is, by designing special devices or machines to offset the delay arising from abnormal production and transportation conditions. In many respects, the situation of the past two years has enabled Canadian manufacturers to make wonderful progress along the lines of more rapid and economic production. There is an old saying that "Necessity is the Mother of Invention," but the value of time has been such an outstanding factor in shell production that the phrase might well be changed to read "Necessity is the Brother of Invention," as necessity and invention have travelled hand in hand during the busy months of the war, making it practically impossible to stay the development of ideas.

The accompanying half tones and line drawing illustrate a special thread milling machine designed and constructed by the Canadian Ingersoll-Rand Co., for milling and hobbing the adapter threads in 8 inch high explosive shell. The operation of counterboring and recessing, and the hobbing of the thread are performed at one setting, thus eliminating the possibility of eccentricity in the various diameters, and insuring a more accurate fit when screwing in the adapters. The machine is so constructed as to give one speed for milling and hobbing. Fig. 1 shows a front view of the machine, while Fig. 2 is the same machine from the rear. The double spindle milling head is fitted to a fixed cross slide, the back end being supported by an auxiliary slide rail secured to the machine bed. The lateral movement of the head is obtained by the handle 1, while the cutters are adjusted to working position by the handles 2, 2, each cutter spindle operating on an independent slide, and the shafts sliding through the gears retained in the housing (3). The rear spindle carries the standard milling cutter for milling the counterbore and recess, and the front spindle carries the thread hob. The entire milling head has a similar action through the right angle gear drive. The outer bearing for the driving shaft is supported by an extension from the bed of the machine, shown in the rear view Fig. 2. Suitable stops shown at (4) are arranged on the side of the cross slide to determine the depth of each cutter.

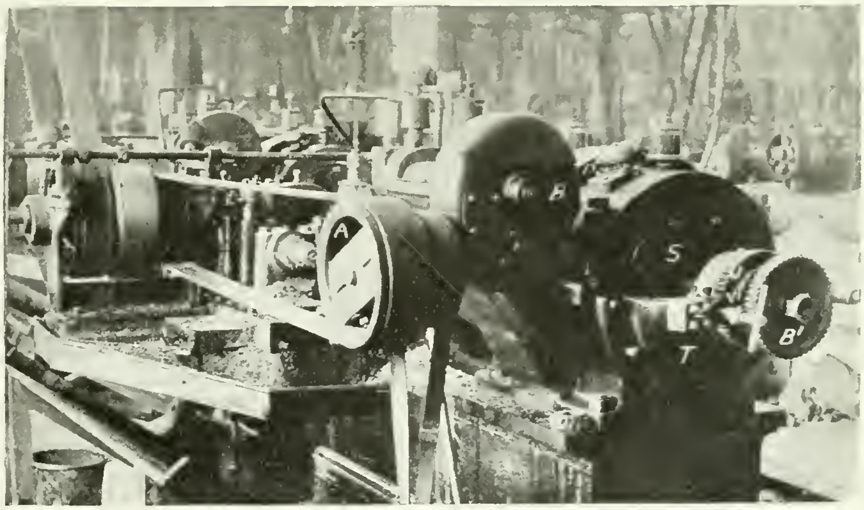

FIG. 2. SPECIAL THREAD MILLING MACHINE—REAR VIEW.

The arrangement of the head stock, with the operating mechanism, is shown in Fig. 3. By means of a train of gears, the spindle and the shell are revolved at a constant speed, both for milling the counterbore and recess, and also the hobbing of the thread. On the opposite end of the drive shaft that carries the pulley A is secured the worm that drives the worm gear C, these being retained in the casing B. The driving pinion D, which is cut in the shaft, engages with the intermediate gear E keyed to the shaft F. The main gear G is cast integral with the spindle H. This spindle has a lateral movement which will be described later. The forward portion of the spindle carries the

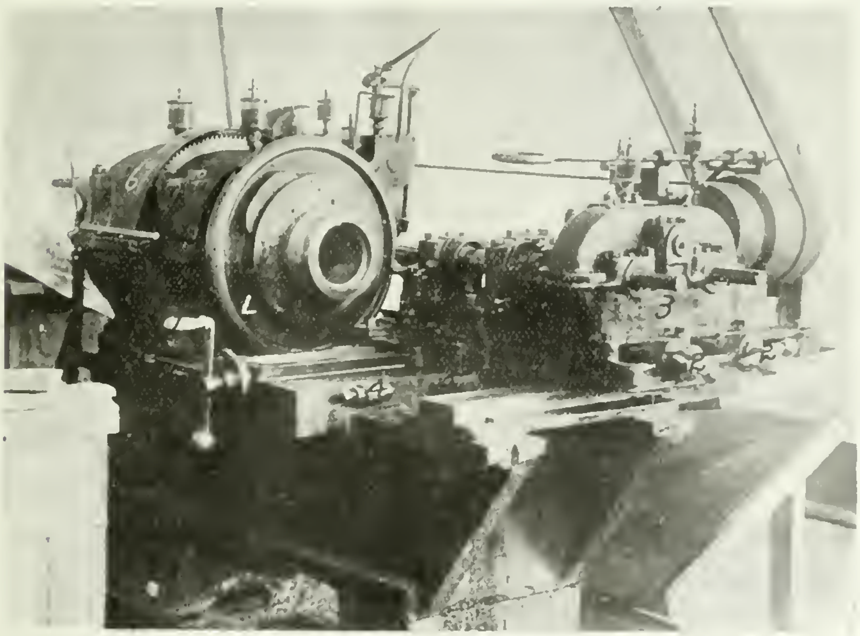

FIG. 1. SPECIAL THREAD MILLING MACHINE—FRONT VIEW

chuck; the piece I being firmly secured to the end. The collet ring J which is threaded to the piece I, operates the split ring jaws K by means of the hand wheel L. Within this wheel is contained a pawl M that engages notches cut in the ring J, by which the chuck is tightened or released. To retain the shell in proper alignment, the inner end is supported on a special bush O fitted to the nose and placed on the plug P, which in turn is screwed in the end of the shaft Q. By means of a tapered pin R, this shaft is rigidly secured to the piece S, that fits on to the end of the main spindle.

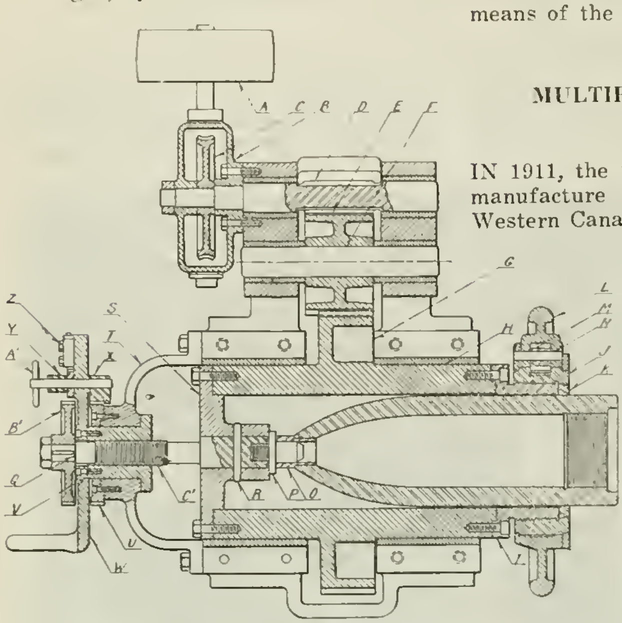

FIG. 3. SPECIAL THREAD-MILLING MACHINE DETAIL.

Fitted to the end of the rear housing is the bracket T. which supports the lateral feed shaft Q and the operating gearing. The ratchet wheel U is bolted to the bracket T, and always remains stationary in relation to the machine frame. Bolted to the nut V is the arm W; one end carrying the two pawls X and Y, the other provided with a handle for returning to initial position. The pocket Z contains the spring that keeps the pawls to their respective positions these being set by the handle A¹. The ratchet wheel B¹ is keyed to the end of the shaft Q, the threaded portion C¹ fitting the nut V, and being of the same pitch as the thread to be cut, in this instance, ⅛ inch. When the counterbore and recess are being milled, the pawl Y is engaged with the wheel B¹, causing the shaft and the nut to revolve together, with no lateral movement in shell position.

After the base is prepared for the thread, and the hob brought to position, the handle A¹ is moved to disengage pawl Y and engage pawl X with wheel U; this keeps the arm W and the nut Y stationary, resulting in the shaft Q revolving in the nut, thus slowly drawing the spindle and shell backwards at the rate of ⅛ inch per revolution while the hob is cutting, so that, when the spindle has made a little over a turn, the thread has been cut. Should the operator neglect to disengage the lateral feed after it has accomplished its object, he is warned by the ringing of a small bell, located on the rear bearing cap, shown at D¹, Fig. 2. Before the next operation is commenced, the fixture is returned to its original position by means of the handle on the arm W.

MULTIPLE DRILL HEADS

By H. Street

IN 1911, the writer was engaged in the manufacture of gasoline engines in Western Canada and, at that time, practically none of the modern productive methods had made their appearance in that locality. True, high-speed lathe tools were used to some extent, but high-speed drills were practically unknown. Slip chucks, tapping attachments, gear cutters, micrometers and other now indispensable tools had not made their appearance. Any job work was usually completed by the man who started it regardless of the various operations encountered. Each man kept whatever drills and other small tools he used carefully under lock and key or hidden beneath some convenient bench, while any extra drills and reamers were to be found in the office. No drawings were in existence, all work being done according to sample. Dimensions for the various engine parts were to be found, however, on the walls above the workman's benches, in blue chalk, having been placed there by the workmen for their own convenience. All drilling was done on the machine shown in the cut and, as engines up to twenty-five horse power were built, some of the difficulties in connection with this class of work may be imagined.

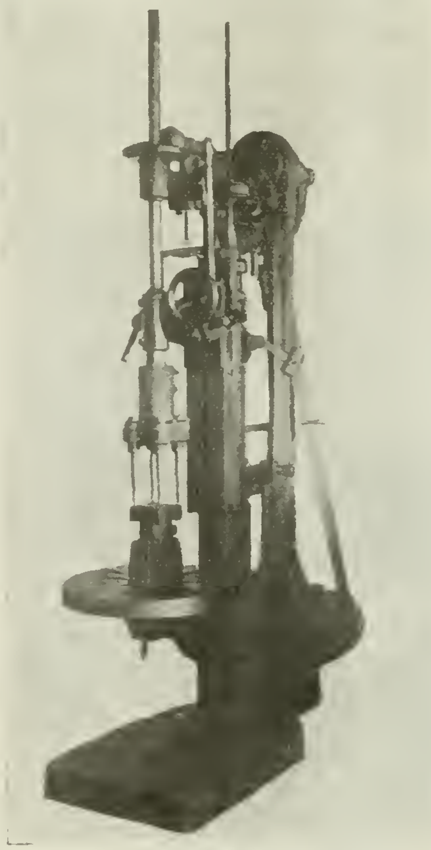

FIG. 1. MULTIPLE DRILL HEADS.

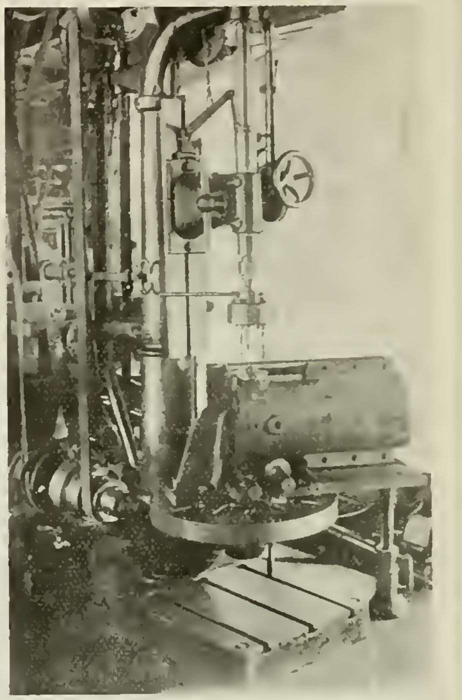

FIG. 2. MULTIPLE DRILL HEADS.

Quite a large number of one and one-half horse power engines were built, these having an air-cooled cylinder, held to the base by four studs of three-eighths inch diameter. The multiple head shown in Fig. 1 was constructed to drill these stud holes, both in cylinder and base. Taper shank drills were used and the spindles extended sufficiently from the body so that the drills could be removed from below. The upper part of the body was split and clamped directly on the sleeve, being prevented from turning by the rack on same. The central driving gear was cut directly on the taper shank and had a bearing in the lower half of the case but none in the upper. In attaching, this central shank was simply pulled out and inserted in the spindle, and the body then slipped over this and clamped in position. The spindles were provided with fiber thrust washers and lock nuts to take the separate drill thrusts, these, of course, being transmitted directly to the sleeve.

The shop in which these heads were made was not fortunate enough to be provided with a milling machine of the modern type nor a dividing head. An old Lincoln type miller was used, and the spindles held in V-blocks while cutting the teeth of the gears. The spindles were left somewhat longer than necessary and a lathe change gear of the requisite number of teeth was attached to this extension which, after the teeth were cut, was removed. A small set screw with lock nut in an angle plate, acted as a dividing head, the tapered point of the screw being run into the teeth of the lathe gear. In order to set the milling cutter to the proper depth, an ordinary one inch outside micrometer was used; with the cutter just touching the blank, a small block was set under the arbor of a height such that the micrometer could just be slipped in under the arbor. The sleeve was then turned down the proper amount and the head lowered until the arbor again touched. This was similar to using an inside micrometer and proved just as satisfactory. By using a little care an excellent job was obtained. The holes in the body were laid by off means of buttons and micrometer so that these could be very acurately bored. No trouble whatever was experienced in assembling, and it is safe to say that a first-class tool room could not have produced a more satisfactory piece of work.

The head just described having proven such a success, that shown in Fig. 2 was next designed. This was for drilling the three holes for the studs holding the make-and-break igniters in the larger cylinders. These holes were properly spaced in relation to the face of the cylinder by the self-centering jig also shown in the photo. This head was provided with a shank to fit a 1¼ inch Magic chuck, and it was thus impossible to attach the body solidly to the sleeve to prevent the rotation of the same. It was desirable to use the slip chuck as these holes were drilled at the same time as the main hole was bored. The rotation of the body was taken care of by the arm seen resting against the column of the drill press. In order to facilitate finishing, the body of the head was made round, and a collar into which this arm was threaded was slipped over the upper part and locked by means of a setscrew. It was thus possible to set the drills in any angular position called for by the jig. The body of the head was, of course, made in two parts and held together by cap screws. The spindles carrying the drills were quite short, extending below only sufficiently to carry the two locknuts and a fiber thrust washer. The combined drill thrusts in this case were thus transmitted directly to the center spindle and this was provided with a large collar and thrust washer resting on the top of the case. The taper shanks of the drills extended up into the upper bearings in which were located the tang slots. It was thus impossible to use a drift for removing the drills and, to perform this operation, a hole was tapped in the upper end of the spindle, into which a set screw could be placed and the drill forced out. This is more clearly shown in Fig. 3.

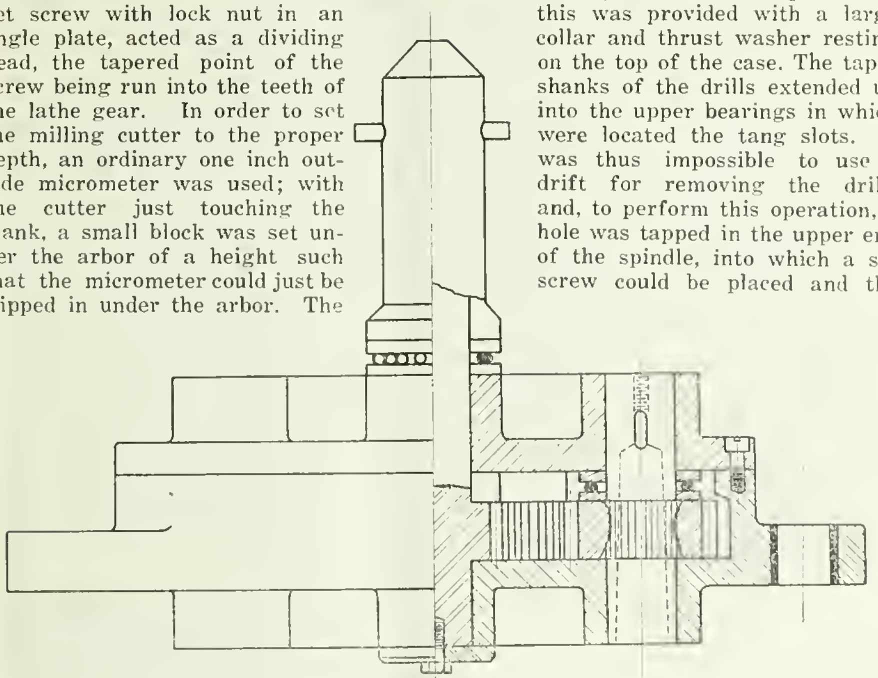

FIG. 3. MULTIPLE DRILL HEADS.

Fig. 3 shows a head which was designed to be used in connection with other tools on a crank case for a multiple-cylinder engine. The crankshaft was provided with three bearings, but the spacing of the stud holes lengthwise of the shaft was different for each bearing, so that it was impossible to drill more than two holes at a time. The head was used in connection with a Wizard chuck and, to prevent rotation of the body, two pins were fastened solidly in the jig plate just outside of the stud holes; these pins extended up into bushings which were carried by projections at each end of the head. By bringing the drill head down over these pins, the drills were accurately located. It was, of course, necessary that the pins be slightly longer than the drills used and, for this reason, the drills were kept as short as possible. A ball thrust bearing was placed over the gear on each spindle and a larger bearing transmitted the combined thrusts to the main spindle. In this case, as in the previous one described, the drills were forced out by means of a screw in the upper end of the spindles.

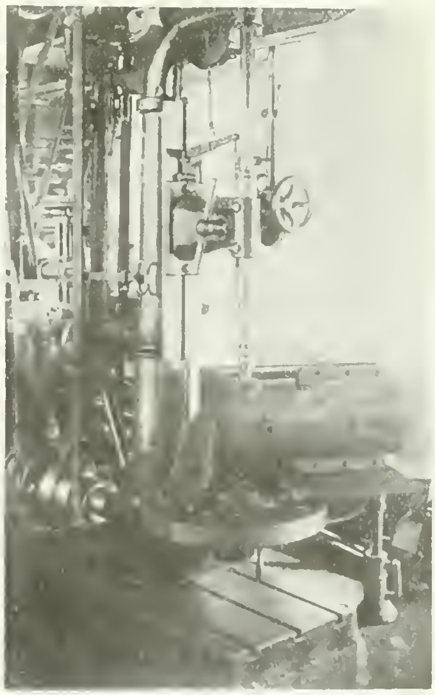
In all the heads described, idler gears were used so that the regular drill spindle could operate in the normal direction. Many times, of course, it is possible to dispense with these idlers but in most cases it is not advisable.

BORING AN IGNITER HOLE

By D. O. Barrett

IN the gasoline engine of which the cylinder shown in the cut was a part, make-and-break ignition was used, the igniter being placed in a bored hole in the side of the cylinder, and extending into the combustion chamber. The hole was of two dimensions, 2⅛ inches in diameter at the inner end and 2⅜ inches at the outer; the shoulder thus formed was finished to a 45 degree bevel, the igniter body having a corresponding shoulder so that a ground seat could be obtained at this point for maintaining the pressure developed in the cylinder. The upper part of the hopper or jacket used on these cylinders was removable, hence this face on the cylinder casting was planed and drilled and tapped so that the casting could readily be held by these holes as the operation of boring the igniter hole was the last to be performed. The work had previously been done on a large wheel lathe by bolting the angle plate shown in the cut to the regular face plate. This plate was about six feet in diameter and the lathe was speeded accordingly, so that one could imagine the length of time necessary to complete the operation. It was also quite a job to centre the cylinder, as this had to be done fairly accurately.

This same angle plate was used on the drill press and supported at the outer end by a jack screw as the excessive overhang would tend to distort the press table. Cap screws were used to hold the cylinder, into the tapped holes previously mentioned. Two roughing bars were provided for the two sizes of



BORING AN IGNITER HOLE.

hole. These were used in the regular Magic chuck, and were further supported by a bushing in the bracket bolted to the drill press table, and which extended into the cylinder the correct distance. Deep chip grooves were milled in the ends of the bars, and leather washers were used to prevent chips getting into the lower bearing. Double ended cutters were used in both instances in order to maintain the size. The smaller cutter was slightly oversize to allow a slight clearance, which was necessary, while the larger was slightly undersize to allow a final finishing cut to be taken by the bar which is shown in position. This final cut was taken by a single-ended tool and was kept quite close to size. The front face of the cutting tool was ground to a 45 degree angle in order to finish the seat in the one operation. The bar above the cutter was threaded and two lock-nuts provided, these acting as a depth gauge. Power feed was used down quite close to depth, with hand feed for the final finish, the stop collars being brought down against the outer face which had previously been planed the correct distance from the center of the cylinder.

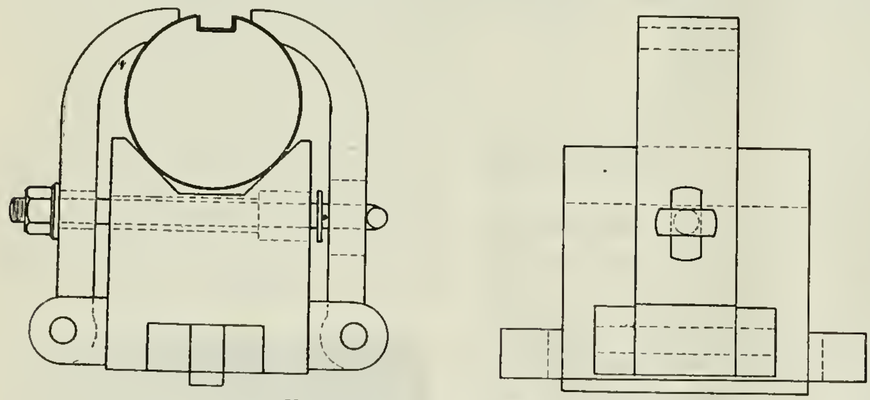
After boring and finishing, three ⅜ inch holes were drilled and tapped in the face for the igniter studs. These holes were drilled, using a multiple spindle drill head which slipped into the Magic chuck and which is described in the Multiple Drill head article also appearing in this issue. This head could be swiveled about the spindle and locked in any position so that it was not necessary that the angle plate be placed in any fixed position in this respect. A self-centering jig was used for locating the holes, and these were also squared up with the turned end of the cylinder as it was necessary that a line through two of the holes be parallel with the center line of the cylinder. This jig was described in our issue of December 17, 1914.

Needless to say, a great saving in both time and patience on the part of the operator was effected, and the resulting job was better and more accurate, as all sizes were obtained without the necessity of calipering or measuring.

V-BLOCK FOR KEYSEATING

By A. S. Loy

HAVING a large number of shafts of a certain size to keyseat, the V-block shown in the accompanying drawing was designed. It was desired that the shafts be clamped directly at the point of cut, if possible, and this was accomplished by means of the two forged clamps which were hinged at the bottom, the hinge-pins running through the two bosses shown. The block itself was held to the milling machine table by a clamping bolt at either end; the tongue for the bolt slot was planed up solid with the block. The two clamps were drawn together by the T-head bolt passing through the block, a slight pressure always being retained against the nut by a spring set into the block and bearing against the washer near the end of spring set into the block and bearing against the washer near the end of the bolt. When it was desired to remove a shaft, the nut was only slightly loosened and the T-head given a quarter turn, when it would pass through the clamp on the one side. This would drop completely down and it was then only necessary to lift the shaft just over the top of the block itself. No clamps were used on the other end of the shaft, this resting in a correspond-



VEE-BLOCK FOR KEYSEATING.

ing V-block with the end against an angle plate to take the thrust of the cut. Due to the fact that the clamps rested on the upper part of the shaft, a large resultant pressure was thus obtained.

SOME C. P. R. FACTS

THE Canadian Pacific Railway has a grand total of 1,500.36 miles of double track, which is greater than that of all the other Canadian railways added together. A statement just issued shows that in Quebec there are 205.11 miles distributed thus: Montreal (Windsor Street) to Smiths Falls yard, 129.20 miles; Montreal West to Brigham Junction, 44.79 miles; Montreal West to Mile End, 7.11 miles; Montreal (Place Viger) to Ste. Therese, 20.11 miles; and Montreal terminals have a mileage of 3.90.

Ontario district has a double tracked mileage of 105.95, made up as follows: Smiths Falls to Glen Tay, 14.84 miles; Agincourt to Leaside, 7.58 miles; Don to Parliament Street, Toronto, 0.78 miles; Toronto to Guelph Junction, 39.10 miles; Toronto (Bathurst Street junction) to Hamilton, 39.10 miles; North Toronto line, 3.93 miles; London terminals, 0.62 miles.

Algoma district possesses a mileage of 180 of double tracks, running between the following points: Romford Junction to Sudbury, 6.80 miles; Azilda to Geneva, 30.20 miles; Roberts to Woman River, 25.90 miles; Nemegos to Esher, 25.50 miles; Healy to Bolkow, 19.10 miles; Depew to King, 27.10 miles; Heron Bay to Peninsula, 8.40 miles; Selim to Pays Plat, 13.70 miles; Cavers to Gurney, 11.00 miles; Fire Hill to Ruby, 4.20 miles; Navilus to Port Arthur, 8.10 miles.

Manitoba district is laid with no less than 643 miles of double tracks. Port Arthur to Winnipeg, 426.30 miles; Winnipeg terminals, 23.20 miles; Winnipeg to Virden, 179.20; Whitewood to Broadview, 14.30 miles.

Saskatchewan district has 210.20 miles of double track, 16 running between Broadview and Grenfell and 194.20 between Indian Head and Swift Current.

Alberta district has 12.20 miles of double track, six running between Swift Current and Java, and there are 6.20 in Calgary terminals.

British Columbia district is equipped with 143.90 miles of double track, distributed thus: Connaught to Glacier, 5.80 miles; Revelstoke to Taft, 24.20 miles; Pritchard to Kamloops, 24.10 miles; Kamloops to Tranquille, 8.70 miles; Ruby Creek to Vancouver, 81.10 miles.

Alternative routes are also in operation between several points, and they are practically equivalent to double tracks. In all there are 489.40 miles of railroad offering alternative routes. Double tracks and alternative routes are parts of the facilities which make the Canadian Pacific the greatest transportation system in the world.

DETINNING APPARATUS

PRIOR to the war, steel scrap in the form of cans, etc., was shipped from England to Germany for removing the tin, solder and zinc. The following apparatus has been recently patented in England to do the work at home. It consists essentially of a slowly rotating inclined cylinder and a stationary hopper with a sleeve encircling the rotating cylinder. The latter has a feed aperture which once in every revolution registers with the aperture on the hopper and allows the cans to be fed into the internal heating chamber. To reduce the friction the latter is mounted upon roller bearings. The heating is effected by gas or oil burners. The heating chamber is surrounded by a firebrick-lined cylinder with outlets for the products of combustion through the short flues at the top. Cans feed into the heating chamber, gravitate slowly through as the chamber rotates, and eventually find their way to the outlet, where they pass down the chute. The temperature is gradually raised along the length of the chamber and is the highest at the outlet end. In the interior of the heated chamber channels are formed for collecting the molten tin and solder.

Worm Gear Design Features and Worm Gear Mounting Detail*

By F. W. Lanchester

Progress that may almost be classed as extraordinary in worm gear design and arrangement is largely due to the research expended and inventive genius displayed by interests responsible for the now front rank prominence of automobile engineering.

IN a paper read before the Institution of Automobile Engineers in 1913, the author dealt with the subject of worm gearing broadly, and more particularly with the Lanchester worm gear, which was the first to be successfully introduced in automobile practice.

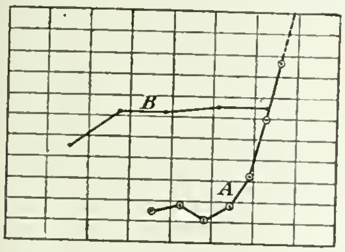


FIG. 1.

It is, perhaps, unnecessary here to recapitulate the distinctive features of worm gear of different types, being enough to say that at the present time there are, broadly speaking, two types of worm gear in competitive employment—the Lanchester gear, which may be spoken of as a variant of the Hindley worm, and the cylindric, parallel, or straight worm such as that marketed by Messrs. David Brown & Sons, Messrs. Wrigley, and others, which may be taken as a development of the ordinary worm gear in common use by engineers for a century or more. Although on the one hand, the Lanchester gear is described as a form of Hindley, and the parallel or cylindric worm as that of ancient practice, such descriptions do not entirely do justice to either the one or the other.

Worm Gear for Power Transmission

Worm gear for power transmission (where mechanical efficiency is the talisman of success) is a comparatively modern development, and the gear used to-day in motor-car transmission and in other cases of power transmission, such as electric lifts, hoists, etc., bear but a very faint resemblance to their fore-runner, which was designed and used for motion transmission alone. Indeed, it is correct to say that, in the more ancient applications of worm gear, a common condition was that the drive should be irreversible; in truth, it was when such drive was wanted, as in a band winch, that the engineer turned his thoughts to the worm wheel as a solution. It is a point of importance that, so long as this irreversibility is a condition, the mechanical efficiency as a power transmitter cannot exceed 50 per cent. We may, therefore, take it that although it may be difficult to draw a hard and fast line between the worm gear of old and the worm gear of to-day, there is, from the practical point of view, as complete a break of continuity as if such a hard and fast line existed.

*From paper read before the Institution of Automobile Engineers, December, 1916.

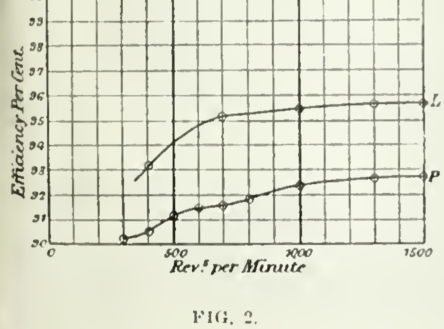

FIG. 2.

Transmission Efficiency

Thus, in the case of motion transmission, it was uncommon for worm gear to have an efficiency higher than 30 per cent. or 40 per cent.; but immediately the problem is changed to that of economic power transmission and the engineer concentrates his attention on the question of mechanical efficiency, a duty as high as 94 per cent. or 95 per cent., or, as shown in the previous paper, even 97 per cent., is to be obtained. In the previous paper the question of efficiency was made the pivot point of the discussion, and the result of the tests made by the staff of the National Physical Laboratory at the Daimler Works were freely used. In the present paper the maker of the gear of parallel type which has been used as a comparison is definitely given; it is the gear of Messrs. David Brown & Sons, obtained direct from one of their customers. It is presumably a fair sample of the gears supplied by that firm. It is of course, more satisfactory to be able to state the maker of the gear which has been subjected to investigation.

The present paper naturally divides itself into two parts—the first part relates to a detailed discussion of the theoretical side of the subject, and may be taken as supplementary to the discussion of the previous paper; the second part relates to a practical examination of the "solid geometry" of worm gear by a new method, and is in fact a detailed comparison of the Hindley and parallel types of worm gear as exemplified in the Lanchester and David Brown respectively. A third section of the paper is devoted to the question of worm gear mounting or housing, a feature in which the practice in respect of the two types does in certain respects present differences.

Part I.

There are a great number of variables—an inconveniently great number of variables—in the design of worm gear upon which its efficiency depends. Without digesting the problem the factors are very numerous; there are thus the diameters of the worm and the wheel and the gear ratio, also the velocity of rotation, and the torque or the horse-power transmitted (either may be specified). Beyond this there is the degree of approximate contact between the pressure surfaces, and there is the question of lubrication. The author's theoretical treatment is based definitely on the fact that the first group of variable factors, namely, the diameters of worm and wheel, the gear ratio, the revolution speed and torque transmitted, can all be represented from the point of view of efficiency in the one quantity, the pitch angle of the tooth and an assumed constant angle or coefficient of friction. For any set of gear between wide limits of load and speed, the angle of friction is in fact almost constant, quite near

FIG. 3a.

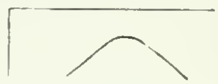

FIG. 3b.

enough so for the purposes of the foundation theory. On this assumption, (i.e., angle of friction = constant), it is then easy to demonstrate that the efficiency will be constant for all variations of torque and speed, also that the efficiency is independent of the diameters of the gears, provided that the pitch angle of the teeth is the same. The approximate truth of this as an experimentally established fact is the justification of the method, and this has been fully established by the National Physical Laboratory tests and report.

Comparative Test Data

In Fig. 1 is reproduced Fig. 42 from the previous paper, in which a comparison is given between one of the tests from the National Physical Laboratory report and one of the so-called tests of a parallel worm cited by Mr. Kerr-Thomas, namely, from a paper by Professor Kennerson. Here, at B, we see the National Physical Laboratory test of a Daimler-Lanchester worm in which from about 27 to 62 h.p. the efficiency does not vary more than one-third of 1 per cent., whereas in the plottings from Professor Kennerson's paper, at A, there is a curve which ranges from 35 to 65 h.p. over a variation of 8 per cent. Now in the results taken with the author's dynamometer, which is certified by the National Physical Laboratory to be true within one-fifth of 1 per cent. (1 in 500), and is probably ordinarily within 1 in 1,000, a considerable range of load was found in every case, over which the efficiency was virtually constant both in the Lanchester and parallel types and similarly the efficiency was also virtually con-

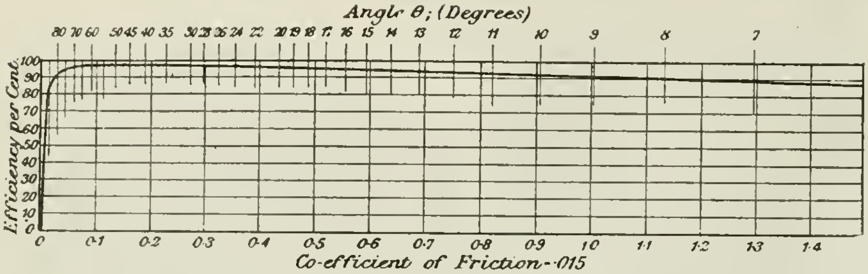

FIG. 4.

stant over a considerable range of speed, though here the variations were, perhaps, somewhat greater. The author showed that there is every reason to suspect the accuracy of Professor Kennerson's results, and at the outset the results of the National Physical Laboratory tests are taken as showing that this approximate constancy of the efficiency over a certain working range for any given set of worm gear is an established fact. The author's own tests (on his dynamometer) of worm gear of the parallel type show clearly the same characteristic feature, namely, the approximate constancy of the efficiency over a considerable range of velocity. Two typical curves are given in Fig. 2.

Falling-off in Efficiency

There are two conditions under which it would appear that the efficiency invariably shows a falling-off: Firstly, when the load per tooth for any given pair of gears exceeds a certain value; the other is when the tooth-rubbing velocity is less than a certain value; also there is, without question, a falling-off in the opposite extremes if a sufficiently great range of speed or load be investigated. Otherwise, the approximate constancy of the angle or coefficient of friction may be taken as established. It is evident that the constant condition corresponds to the minimum value of coefficient, or, conversely, the maximum of efficiency. In the nature of things, where A is a function of B, A is approximately constant in respect of B when A is a maximum and when A is a minimum. This is as commonly expressed on the equation for maximum or minimum value as $dA/dB=0$. Thus there is nothing extraordinary in the fact as stated. Its importance from the point of view of the theory of worm gear efficiency lies in the fact that the maximum is rarely, if ever, found to be a "peak," it is rather a "tableland," of the type shown in Fig. 3a, rather than the type shown in Fig. 3b.

It is a further point of importance in connection with the theory of worm gear that the practical range of usage over which efficiency is important does not carry us into the regions where the higher coefficients are met with. Indeed, it is actually the increase of the coefficient and falling off in the efficiency under excessive load that determines sharply the maximum load limit to which any given pair of gears may be subjected, for a very moderate increase in coefficient above its normal "least value" results in, or is evidence of, the partial breakdown or rupture of the lubrication film and the disintegration of the gear. This is the case, whether it be of the Lanchester or parallel type; in fact, the increase of the coefficient under heavy loading is the first sign of incipient lubrication failure, and so the point of fall in the efficiency curve under heavy loading may be taken as an invariable indication, in the comparison of any two pairs of gear, of their relative higher load limits.

In engineering practice we are accustomed to meet problems in which the coefficient of friction is legitimately treated as constant; in all these problems certain actual variations exist, but the underlying fact is so nearly true that the basic theory is correctly founded on the assumption of a constant coefficient of friction, and such changes as are met with are considered as variations from this constant value rather than in relation to the zero. The tests published in the author's previous paper fully establish the fact that power transmission worm gear comes legitimately into the group of such problems, though it was by no means certain prior to the paper that this was the case. If such results as those of Professor Kennerson were true, we should not be justified in basing any arguments on the constancy of the frictional coefficient, and the foundation of the theory of worm gear efficiency would consequently become far more complex and difficult than is actually the case.

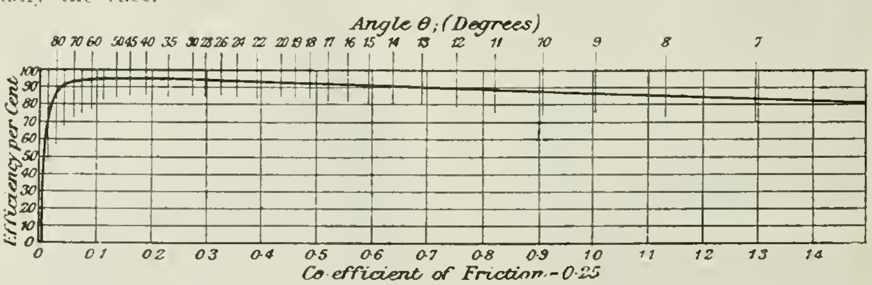

FIG. 5.

So far we have dealt with the group of factors which determine the efficiency as based on the coefficient of friction; in other words, we have confined our attention to the group of variable quantities which suffice to determine the efficiency once the angle of friction is stated, and have seen that these are summed up in the one quantity, the pitch angle. It is clear that the assumption of a constant angle of friction simplifies matters to the utmost possible extent, for in place of the multitude of different variables we have only to consider the pitch angle of the tooth, that is, the angle relatively to the worm axis—all the quantities on which this angle depends are then accounted for. The efficiency is given by the simple graph as in Figs. 4 and 5.

The other half of the problem is to deal with the factors on which the constant or minimum coefficient of friction for any given pair of gears depends, and more broadly the factors on which the extent of the approximately constant range depends, for it is the extent of this range in direction of high loading which determines the maximum output capacity at any given speed of a pair of gears, and so determines their commercial value as an engineering asset.

Commercial Value of High Power Transmission

The commercial value of high power-transmission capacity from an automobile standpoint may be regarded as even greater than from an engineering standpoint, for the importance of weight-saving is paramount. Thus, if two sets of gears, one of 8-in. and another of 10-in. centres, were to possess the same horse-power capacity for a given revolution speed, and even (owing to a difference of design or material) were to cost the same, one might be justified in considering them equally favorably in any ordinary engineering problem, but if the 8-in. centre gears weigh proportionately less than the 10-in. centre set, they will be far more valuable and a more saleable article from the point of view of the automobile constructor and user.

The efficiency curve in any case is of the type represented in Fig. 3a. At very light loads the efficiency may be poor owing to the fact that oil is being churned in the gear and churned in the bearings, since the power so consumed is virtually independent of the load. On the other hand (as already pointed out), the efficiency curve falls at heavy load owing to the thinning and incipient breakdown of the lubricating film.

It has been regarded as open to question to what extent the magnitude of minimum coefficient (maximum efficiency) is controllable; the author has found evidence of considerable variation according to the type of gear and lubricant. If it were not controllable, then the maximum efficiency for every individual pair of gears under the most favorable conditions would depend definitely upon the pitch angle of the tooth, and would be the same whether the gear is of the parallel or Lanchester type.

Tooth Surface and Load

It has also been regarded as an open question whether the breadth of the "tableland," if one may say so of the efficiency curve, can be increased. Thus it might be argued that if, by obtaining better proximate contact (by any means) the breaking-down of the lubrication could be persuaded to take place at a higher tooth load, this same greater proximity of the tooth surfaces may result in a higher viscous churning resistance, and so take off the range of coefficient at one end what it puts on at the other.

Although the author is prepared to take a liberal view and say that these points are open to controversy, opinion, as based on present-day experience, is decidedly that a better type of tooth contact corresponds to an absolute lower minimum coefficient—probably due to a thickening of the oil film over the load-bearing area, and that this does not of necessity add to the churning loss.

The benefit of obtaining high tooth loads by improving the proximate contact of the tooth does not, however, depend intrinsically on an actual increase in the range. Even if what be gained at one end be lost at the other, the result of improving the proximate contact of the teeth (by whatever means accomplished) is to enable a given pair of gears to transmit a higher standard of loading. Conversely, for a given horse-power transmission, a smaller and lighter set of gears may be employed, with (a) a saving of money in material and machining, and (b) a saving of weight in the gears themselves and in the mounting, with a consequent better performance of the car, and, due to the reduction in the unsprung weight, less wear and tear on the tires, etc.

Automobile Application

We, therefore, realize that the essence of power transmission worm gear for automobile purposes is to be sought in achieving the highest tooth load compatible with the maintenance of the oil film and the approximate minimum coefficient of friction; any and every improvement in the area of proximate contact of the tooth surfaces in engagement with one another will be reflected in a bigger output from a given pair of gears and a reduction in the size and weight of gears for a given performance. It is one of the main objects of the present paper to examine the differences and relative merits of the Lanchester and parallel types of worm gear in this respect.

The advantage of reducing the centres and diminishing the size of a pair of gears for any given automobile is not only a matter of weight saving, important though this may be; it is equally a matter of compactness of design. It is and has been one of the difficulties in the application of worm gear to the back axle that if the worm be arranged beneath the wheel the ground clearance is jeopardized, and if it be arranged above the wheel the body clearance has to be cut fine. The result of experience appears to show that for the home market the question of ground clearance is the less important; a full size touring car with 35 in. driving wheels and a worm gear of 6-in. centres can be designed to give an 8-in. clearance in the centre of the rear axle, and this has proved itself ample for use in the British Isles, where consequently the underneath worm is widely used.

Worm Location

It has been reported from Colonial sources that the worm underneath is objectionable as not providing sufficient clearance. The author is doubtful whether this objection is generally valid; the same objection once carried weight in commercial circles with regard to the home market. It sems incredible, with the wheel base now accepted, some 11 or 12 feet or more, that if a clearance of 12 in. is required under the axle, anything less than 18 in. or 20 in. can be sufficient under the body of the car. Apart from the mere question of actual clearance, a contact between the road or chance boulders and the flywheel or base of the engine is liable to prove far more serious than the contact of the comparatively robust housing of the worm gear. However this may be, the objection exists, and has been sufficiently strong to induce many of our constructors when adopting worm gear to place the worm above instead of below.

When the worm is placed above the axle the question of body clearance gives trouble. Now the fashion, at least for the home market, is to keep down the floor level as low as possible—a "pleasure" car with a high floor level and centre of gravity is to-day unsaleable, in the author's opinion rightly so. The result of this is that where cars have the worm placed above the axle it is often found necessary to gouge a piece out of the rear body and fit a casing which protrudes through the rear body floor in order to provide the necessary clearance.

Beyond the above, the cooling of the worm box with the worm on top is inferior to what it is when the worm is placed underneath; the actual importance of this point depends upon the general design of the car. There is thus every inducement, apart from the already important consideration of weight, to endeavor by all possible means to obtain the maximum horse-power or torque transmission capacity from a gear or any given size.

SHAFT TROUBLES

By John Ellethorn.

WHEN ammetic and voltmeter readings are taken on a line shaft and a heavy friction load is shown, it is usually stated by the investigator that the shaft is out of line and not leveled. In a recent test, in a laundry plant, where the friction load registered 45 per cent. of full load, the expert stated that the shaft was out of line. The shaft was re-lined, and bearings repaired, at considerable cost in time and money. New readings were taken, but the friction load had increased to 52 per cent. of full load.

The engineer, who was just an ordinary fairly intelligent sample of the profession, directed the attention of the investigator to the fact that the pull of the countershaft belts was practically all at one side of the line shaft, and that the belts from the countershafts to the machines was perfectly vertical, which meant a very tight belt.

In re-lining the shaft the cross belts, which were very short in some cases, and therefore had a high belt tension, had their tension increased, which would account for the extra seven per cent. All the cross belts were removed from the line shaft and a test showed a friction load of 5 per cent. only, a decrease of 35 per cent. from the first readings.

In many cases when a belt begins to slip, the man in charge will cut out a piece of the belt, thus tightening it up and incidentally increasing the friction and stretching the life out of the belt. The intelligent use of a good belt dressing would often save considerable work and prolong the life of the belt for many months.

Many instruments are made to simplify the re-lining of shafts. Some are ingenious and useless and some are good if used intelligently and under proper conditions. If it is possible to have the power cut off from the shaft for a sufficient time to do the work, nothing can beat the lines, levels, plumb-bob, rule, and "gumption." I have seen men endeavoring to line a shaft while another shaft a few yards away and machines by the dozen were in full swing, causing such a vibration that no matter how tight the line was drawn, it would vibrate, while the "bubble" in the level would proceed to do a "tango" every time it was placed upon a hanger or bearing, and it was impossible to keep the plumb-bob from swinging. The use of one of the patented devices was no better. Therefore, do your line shaft lining when there is a shut down, Sunday, if no other day is available. If you shy at Sunday work, do it at night and sleep during the day. Of course, in some solidly built buildings the vibrations from one shaft to another would be next to nothing, but these later remarks refer to the other kind.

Make sure the fault is rightly located if the friction load is big. See that the hangers are not set too far apart for the diameter of the shaft and the load carried, that the diameter of the shaft is great enough to stand the pull at full load without springing, that the pull on the shaft, at the pulleys, is as close to the hangers as possible, that the pull is not all at one side of the line shaft, that as few belts as possible are vertical, and that the use of a good oil or grease is not forgotten.

MACHINISTS' INSTRUCTION COURSE—XVIII.

By J. Davies.

A VERY useful tool for planer or shaper work is a number of small gauge blocks made to definite sizes. These blocks are used for setting the tool when a piece is to be planed to a number of different sizes. The gauge is placed upon the work and the tool set to just touch it, or to pinch a thin piece of paper placed upon it, as shown in the illustration, Fig. 67. This is a much

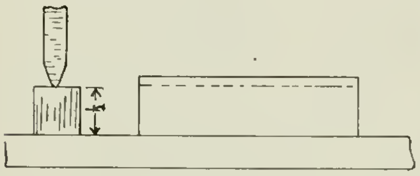

FIG. 67.

quicker and more accurate way than taking a trial cut and then measuring up the work.

Planing to Templet

If a large number of pieces are to be planed all to one size and form, particularly if it is a complicated form, after carefully planing the first piece, it should be bolted to the planer table and used as a gauge for setting the tool for others. If the piece is too large to be conveniently placed on the table behind another piece to be planed, as is the case in planing lathe or planer beds, etc., it would be necessary to make a special tool setting gauge for the job, which would be dependent on whether there was a sufficient number of pieces to be planed to make it worth while. See Fig. 68.

In cutting dove-tails or slots, one of the things to be contended with is the drag of the tool on the return stroke. If the dove-tail or undercut is not too great,

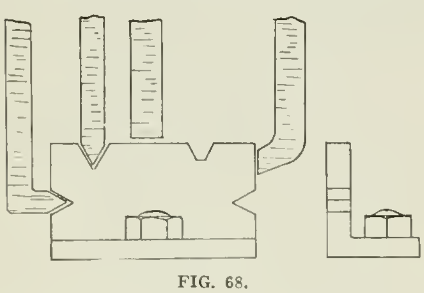

FIG. 68.

by swinging the top of the tool block away from the surface to be planed, the tool will clear itself on the return stroke, as it will lift away from the work, owing to the angle to which the tool block has been set over.

Planing Deep Slots

If cutting a very sharp angle or slot, where there would not be room for the tool to lift away from the work, there are two alternatives, either to lengthen the stroke at each end of the job, so that the tool will run clear through the slot and can be lifted up at the end of the stroke clear of the slot and put down again at the other end, or the tool can be clamped rigidly in its place. In a certain machine shop recently the writer saw the simple device shown at Fig. 69, doing such work, and it seemed to give every satisfaction. A common door hinge was clamped to the back of the tool in such a way that it would bend on the forward stroke, and then, when the tool got past the end of the slot, the hinge would fall down, and on the return stroke it would lift the tool clear of the slot.

Tool holders are commonly used in most planer and shaper work. They are an advantage, not only from the great saving in tool steel, but from the facility with which the small inserted tool can be removed and ground up to shape. One special form of tool holder, peculiar to planers, is for holding three or four inserted roughing tools. These are called gang tools. It has been found that the resistance of a cut varies as the square of the thickness of the chip, and that a rougher feed can be taken if the cut is divided up among three or four tools than would be possible if only one tool was used. Owing to the fact that the cutting edge of planer tools are in advance of the point of support, there is a tendency for the tool to spring into the work, particularly when using a cutting-off or parting tool, as the tool is somewhat slender and springs more readily. This can be largely overcome by using a goose neck tool, bent in such a manner that the cutting edge will come behind the point of support and the pressure of the cut will cause the tool to spring away from the work, rather than into it (see Fig. 70).

Cast iron should be finished with a broad flat tool unless the metal is very hard and causes chattering when the breadth of the tool will have to be somewhat modified. In roughing out cast iron it is sometimes advisable to take a cut with a chisel along the edge, where the tool leaves the work, to prevent it breaking away and leaving ragged edge.

Milling Machine Work

The milling machine is one of the essential machines of the machine shop. It is capable of a greater variety of work than any other machine in the shop. They are built in a great variety of forms for special work, and are given names accordingly, but since the universal miller, with its attachments, can be used for every imaginable kind of a job within the capacity of the machine, that is the one which shall receive principal consideration.

It would be almost impossible to enumerate every operation of which the universal milling machine with its attachments is capable, and it may be that different people would give the same operation different names. Following are a few of the names that are most commonly used in the workshop, also a few of the more general operations.

Plain milling consists in producing a

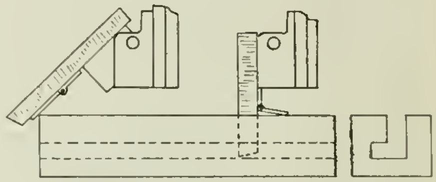

FIG. 69.

flat-finished surface, which can be done in three ways—either by feeding the work to the milling cutter in two horizontal directions—that is, lengthways or crossways, or straight up and down.

Form milling—that is the production of some complicated shape by the use of special formed cutters.

Gear-cutting, drilling, boring, reaming, angular milling, grooving, keyway-cutting, twist drill-making, end mill work, hobbing—that is the making of worm wheels by the use of hobs—slotting or sawing, and many others.

The first consideration in any kind of a milling job is naturally, how is it to be held? It may be secured directly to the table, held in a vise, bolted to an angle plate, held between centres, gripped in a chuck, carried on an arbor, bolted on parallels or V-blocks, or held in some special fixture or jig. However, it is held, it must be held rigid and care must be taken not to spring or distort the

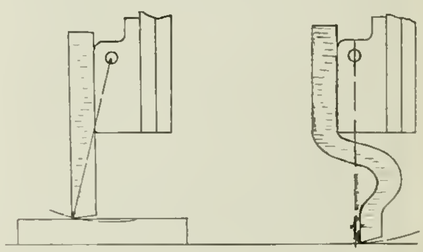

FIG. 70.

work in fastening it down. Generally speaking, the same kind of plates and bolts found around the drill and planer table are used; but greater care should be taken in setting up, as there is more strain on the job during a milling operation than there is in either shaping or planing.

THE MACHINE SHOP OIL CAN

By J. H. R.

THE ordinary oil can with which all machine shop men are more or less familiar, is in itself an apparently insignificant part of plant equipment, but its importance to maximum efficiency is very seldom given serious consideration. Every operator should be provided with his own particular oil can and should make it a point to see that it is not only used, but used in such a way that it assists him in his work and not as a means of creating trouble, preventing the proper working of the machine, as is often the case when care is not given to this serviceable but much abused article. No machine will run for any length of time unless properly lubricated, and by proper lubrication we do not mean an abundance of oil, but the application of the oil in such a manner that the highest factor of efficiency is obtained from its use.

While plenty of oil is one of the essentials of machine operation, it is very important that this oil should be entirely free from any injurious substance; and this latter feature is one of the things that is directly up to the man that uses the oil can. When it is necessary to put oil on any particular part of the machine or into any of the bearings, the first duty of the operator is to see that the oil can is entirely free from dirt or grit that might find its way onto the parts or into the different oil cups or chambers. When an oil can is not in use it should be kept in a place where the flying dust and grit from the various machines cannot get to it, as the very nature of the liquid is an attraction for foreign particles. Keep the exterior as dry and as free from oil as is possible, and never attempt to use the can unless you first, with a rag or piece of waste, remove any trace of grit from the spout. Many men will pick up an oil can and inject a supply of "oil" into a bearing without a thought as to where it has been lying for some time, with the result that considerable dirt may enter the oil cup along with the lubricating fluid. Immediately, results may not prove serious, but the foundation has been laid for the destruction of the bearing, which will eventually take place if this practice is continued.

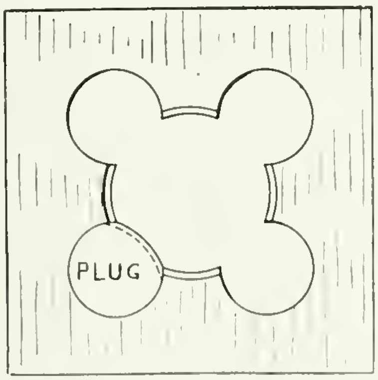
Not so very long ago I noticed a young lad oiling his machine, the oil can he was using being of the kind where it is difficult to say whether the oil comes from the outside or the inside. In the course of his oiling procedure, the can slipped from his hand and fell beneath the machine into a pile of cast iron cuttings; he stoops down, picks up the can, and without wiping off the spout, continues to inject "oil" and other forms of evil, into the remaining oil holes. This is only one of many instances, of a similar nature that has come to my notice.

During the early stages of the shell activity, when unskilled labor was being profusely employed on the various machines, the want of experience in machine shop fundamentals, was one of the features that made it difficult for the different plant executives. In many cases machines would be operated under the most unsatisfactory conditions; partly through a lack of knowledge on the part of the man running the machine, and partly to his anxiety to make as much as he could by simply working his machine and not feeding it. I have seen operators using double the power to move the saddle of a lathe that would have been required if proper lubrication had been used on the ways of the lathe. Spindles and shafts have become seized through the neglect of the operator to provide sufficient oil in the bearings, or by allowing grit to enter the openings when putting in the oil. To overcome this objectionable feature in the operation of machinery under existing conditions, many plants have adopted the method of having a special oiler, whose duty it is to keep the various bearings on the different machines well oiled, and the openings covered from the atmosphere, thus almost eliminating the necessity of extra repairs. However, no matter what system is in vogue, it is highly desirable that greater attention be given to that small but highly essential accessory of the machine shop, the "insignificant oil can."

CUTTING UNDERSIZE THREADS WITH OVERSIZE DIES

By J. E. McCormack

CUTTING either a neat or an undersize thread with an oversize solid die may be accomplished in a simple manner by threading a piece of rod with the die and cutting it off a little longer than the thickness of the die. The piece is then filed or ground to fit snugly into one of the chip recesses in the die, keeping an untouched part of its threaded surface projecting into the work space. This plug should be filed or ground off a little at one end on the threaded face to correspond with the shape of the cut-



CUTTING UNDERSIZE THREADS WITH OVERSIZE DIES.

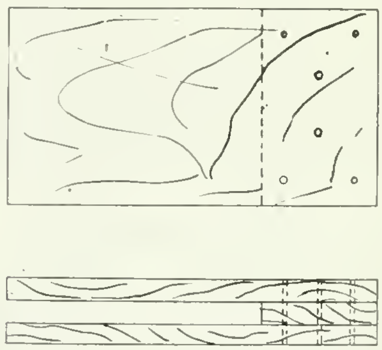
ting faces of the die. The work should first be threaded with the die alone, and then the plug used for obtaining the finished size. Thin strips of metal, cloth or paper may be inserted behind the plug if smaller size is wanted.

The same idea has been successfully applied to taps occasionally by fitting a plug in the groove of exact size taps to make them cut big. It will work if the groove in the tap is sufficiently angular and with most taps it works alright until backing-out from a blind hole, when the piece rocks backward and acts like a ratchet dog. Where through holes are being tapped the piece can be put right down through and the trouble avoided.

PROTECTING BELT LACES FROM VERMIN

By J. E. McCormack

LAST summer the plant where the writer is employed was troubled with vermin which ate the leather lacing out of the rubber belts when machines were occasionally idle for a few days; even belts in regular use would sometimes have their lacing eaten during nights and Sundays. While experimenting



PROTECTING BELT LACES FROM VERMIN.

with various types of metal lacings to find one suitable for use on all of the belts, we protected the remaining leather lacings, when at rest, by placing over them shields made as per sketch, the dimensions varying with the size of the belt. The shields were made of 3 pieces of 1 in. board, nailed together and provided with a hole for a cord which was tied to the guard rail to prevent the shield from being carried to either pulley in case the belt was started up before the shield had been properly removed.

BUSINESS MAGNANIMITY

A CERTAIN big corporation, says the *Wall Street Journal*, was fortunate some years ago in getting a contract for a long period of years for raw material from a smaller corporation. It came to pass that prices of labor advanced sharply, so that the corporation which sold its raw material to its big client was making little or no money on its contract. Then the big corporation said: "you are not making any money out of the goods you sell, whereas we are making more money than we have ever made on our finished products. We'll do the square thing and pay you more than you are legally entitled to." This is the understanding of Wall Street interests. The big corporation referred to in court actions as merciless and contemptible is the United States Steel Corporation. The little brother benefited is the Pittsburgh Coal Company. Such things do not happen every day.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

THE GERMAN 42-CM. HOWITZER

THESE notes are the result of an accidental encounter with one of the 42-cm. howitzer batteries while on a visit of inspection to the 6th German Field Army, on the Arras section of the west front, between October 1 and 8, 1915. The battery was first met on the road at Henin-Lietard near Lens, on October 1, where the officer in charge explained the system of transportation. On October 5 the battery was again inspected by special permission, this time on the road near Pont Maudit, when the loaded wagons were uncovered and a number of the details explained. On October 8 the battery was inspected in a firing position near Estevelles, while bombarding Loos, which had been taken by the British on September 25, during the then recent great offence of the Allies.

Method of Transportation

The battery consists of two pieces. Each piece with its carriage and manœuvring appliances is transported on five steel-framed carriages with built-up riveted steel wheels. Each carriage is of a special design to suit its load. Each wagon is drawn by a motor tractor, to which it is close-coupled by a yoke and coupling pin. The whole battery, therefore, comprises 10 units, each unit being made up of a wagon and motor. In addition, four other ordinary motor trucks of 4 or 5 tons capacity accompany the battery, carrying small parts, supplies, etc. Owing to the size of the units, the battery takes up considerable road space and makes a formidable appearance. When inspected on the road, all wagons were covered with freshly-cut boughs, as a screen against aviators, and care was taken, when halted, to stop under the trees bordering Chaussee. The loaded wagons are normally covered closely with tarpaulins, so that nothing can be seen. The wagons of each piece are numbered and designated as follow:

No. 1 wagon—The appliance wagon, carries the material required in assembling the howitzer and carriage and for dismounting same. The principal item of the load is the four-legged gin and winch, with block and tackle. The legs of the gin are hollow steel spars fitted with couplings. The appliance wagon also carries heavy steel anchor pins, snatch blocks, and certain parts of the carriage, such as elevating and traversing gear, loading cranes, etc.

No. 2 wagon.—The platform wagon, carries a one-pieced steel-frame, U-shaped platform, with two box-girder steel rails for hauling the carriage into place on the platform.

No. 3 wagon.—The cradle and spade platform wagon, carries the howitzer cradle and a huge spade of special construction, to be described later.

No. 4 wagon.—The carriage wagon, is the carriage proper of the piece, the hind wheels of the wagon constituting the carriage wheels as in a field gun, the front wheels of the wagon being used only for road transport and being uncoupled from the trail and replaced by the spade when the piece is mounted for firing.

No. 5 wagon.—The howitzer wagon, carries the piece, which is supported in the grooved side rails of the wagon by projecting ribs on the side of the howitzer.

Motor Wagon

The motor wagons attached to No. 1 are larger and more powerful than the others, having motors of 60 to 80 h.p., and being provided with a steel-cable drum slung under the chassis. This drum is driven by the engine and is used for the purpose of hauling the different wagons on and off the platform. The motor wagons attached to wagons 2, 3, 4, and 5, have engines of 40 to 50 h.p., and are of different systems and manufacture, with the avowed intentions of trying out the different types of motor tractors under service conditions. Among the manufacturers noted are Daimler, Benz, Pedens and Pohl. All motor tractors are essentially of the same type as developed in Germany for agricultural purposes. They all have cleated rear wheels about 8 ft. in diameter, with tyres 12 to 14 in. broad.

In the Pohl system the rear wheels have, in addition to the cleats, a system of steel blades operated by an adjustable eccentric on the axle, and working through slits cut at right angles through the steel rim. By proper adjustment of the eccentric these steel blades can be set to project beyond the surface of the steel rim, and thus afford a better grip on the ground than is possible with the fixed cleats. This arrangement is similar to the feathering arrangement sometimes used on the paddle-wheels of steamers, and is stated to give increased adhesion, particularly on soft ground.

All engines on motor tractors are four-cylinder, water-cooled, with magnetic ignition, of simple but rugged construction. Transmission of power to the rear axle is by chain drive. Steering is effected through the medium of a quadrant and a chain, much the same as is used in heavy road rollers. One make of tractor had but one wheel on the front axle.

Assembling of the Piece and Carriage

For convenience in assembling the piece and carriage in the firing position, the various wagons of the battery are formed in column with the two No. 1 wagons at the head, followed by the two No. 2 wagons, then the two No. 3 wagons, and so on. When traveling on metalled or hard roads, the wagons carrying parts of the carriage and the piece move on their ordinary wheels, which have smooth steel rims about 10 in. wide. When moving over soft ground such as when leaving the road to move into a firing position, caterpillar rims or girders are fastened to the front and rear wheels of the loaded wagons. These rims consist of 12 segments for the hind wheels, which are some 5 ft. 6 in. in diameter, and of eight segments for the front wheels, which are about 3 ft. 6 in. in diameter.

The position of the emplacements having been determined, and the caterpillar rims attached, the column is moved by the head to the designated position. Each No. 1 wagon moving to the emplacement of its piece is followed by the other wagons pertaining to that piece. No. 1 wagons are halted at the emplacements and, after erecting the gins and unloading their loads, are hauled aside. The motor tractors of the No. 1 wagons then take up their position a short distance to the front of the emplacement, from which point they can haul the remaining wagons up on to the platforms by means of the cable drums. If the ground does not admit of a straight-line pull, the tractors are located at any convenient point and the cable led around a snatch block to an anchorage.

No. 2 wagon is then hauled under the gin and the platform lifted clear by the gin, after which the wagon is hauled away and the platform lowered to the ground previously levelled for the purpose. When the ground is firm no other preparations than the levelling are required. When the ground is soft various expedients can be employed, either excavating to a firmer foundation, filling in with broken stone, or laying of a grillage of planks. The steel platform is lowered upon the prepared surface, carefully levelled, and oriented in the general direction of the fire.

No. 3 wagon is then hauled on to the platform, using the steel box-rails for this purpose, and the spade unloaded and temporarily laid on the ground. The cradle is then hoisted clear and the wagon hauled away, leaving the cradle suspended from the gin. No. 4 wagon is then hauled on to the platform, with caterpillar wheels attached, and approximately centred on the platform. The cradle is then lowered into the carriage, the cradle trunnions resting in the trunnion beds. The front wheels of No. 4 wagon are then uncoupled from the wagon and removed.

No. 5 wagon is then hauled up, its side rails being brought into line with grooves on the inside of the cradle, and the howitzer pulled off, the machined ribs on the side of the barrel engaging in grooves in the cradle as they leave the grooved side rails of the wagon. The spade is then hauled into position and coupled to the trail of the carriage, the traversing and loading gears assembled, leaving the piece ready for firing. The battery commander stated that under favorable conditions the battery could be set up for firing in three hours.

The Spade

An interesting feature of the mount is the "sporn," or spade, which serves both to check recoil of the carriage and as a traversing rack for changing direction horizontally. It consists, essentially, of a huge segment of a circle of peculiar radial cross-section, being built up of steel plates and frames, measuring about 11 ft. on the chord. The radial cross-section measures about 5 ft. high and 6 ft. broad over all. The upper surface of the spade is in two levels, on the lower of which rests and slides the carriage-trail. In the vertical surface connecting the two upper levels lies a rack into which a pinion fastened to the trail engages. By operating the hand wheel on the pinion shaft, lateral motion is imported to the trail. To the lower leg of the spade are bolted six blades, each approximately 2 ft. wide, which engage the ground and check the recoil of the carriage. If needed, a trench can be dug for the lower edge of the spade, and the back of the trench filled with broken stone and gravel well tramped into place to secure better resistance.

The Caterpillar Rim

The caterpillar rim consists of a double row of shoes, the outer shoes being about 22 in. wide by 26 in. long, and 2 in. thick, apparently of solid steel. The inner shoes are flanged so as to engage the wheel rim, and are hinged to the outer shoes at their middle. The slack of the girdle is such that at least two of the shoes lie flat on the ground, and but for a small sector of arc three shoes are on the ground. The arrangement therefore insures that the weight of the wheels is always distributed to the ground through at least two outer shoes, resulting in such a distribution of weight as to enable the wagons to be hauled over soft ground. In this connection the battery commander stated that the motor tractors with caterpillar wheels could haul their loads over considerable obstacles, such as deep road ruts, shallow side ditches, low banks, etc.

The Howitzer

A more graceful and well-proportioned piece of ordnance could not well be imagined than the German 42-cm. gun. The bore between the lands measures exactly 42 cm., although the gun does not look so large. The thickness of the metal at the muzzle is surprisingly thin, not over 3½ ins. by estimation. The length of the gun over all is exactly 5 m., determined by measurement. The diameter of the breech is about 4 ft. The fermeture is the well-known Krupp sliding block, and is completely opened or closed by three turns of the operating crank.

Personnel

The personnel of the battery consists of 280 men, commanded by a captain. Of the men, 200 are foot artillerists and the remainder are chauffeurs and mechanicians, most of them from the shops of the several motor truck manufacturers and from the Krupp works. An ordnance expert from the Krupp works was attached to the battery as a Lieutenant of the Reserves. In the actual firing of the battery, 25 artillerists were required at each piece.

Ammunition and Ranges

The shell weighs about 820 kgs., or about 1,800 lbs. It is about 3½ or possibly 4 calibres long, and has the ordinary ogival head. The powder charge is contained in a large brass case about 18 in. high. The most effective range, namely the one giving the maximum accuracy, was stated to be 9,400 m. The maximum range is much greater, but no information would be given on this point. The ammunition is transported in a special motor truck column which was not encountered, and no details as to loads or number of wagons could be obtained.

Firing

On October 8, 1915, this battery was observed while firing on the British position at Loos, for which purpose it had been emplaced in a quarry pit pertaining to a cement mill near Estevelles. The floor of the pit is about 18 ft. below the general surface of the ground, and is entered by a ramp with a slope of about 1 in 8. The howitzers were set up close to the almost perpendicular bank of the pit, about 150 ft. apart. On each side of each piece was a shell and powder store, formed by a slight excavation in the bank and covered by paulins.

In loading, the pieces are brought to a horizontal position. A shell is brought from the shell store on planks laid on the ground and placed under the loading crane, from which is suspended a shell tray. The shell is rolled on the tray and clamped in place, a brass case with powder charge is set on the frame forming part of the tray, and the whole load hoisted by the crane, six men operating the hoisting crank located near the end of the tray, three on each end. The tray is centred in the breech and the shell pushed into the chamber. The rammer staff, which is comparatively short, has knotted ropes fastened to its rear end; these ropes are led forward and, with some dozen men manning the staff, the projectile is rammed into its seat, giving forth the clear metal ring that indicates good centering. While ramming the men stand on the trail of the carriage and on the upper surface of the spade. The brass case containing the powder charge is then lifted from its frame and pushed into the powder chamber, after which the piece is elevated by the elevating crank in the front and traversed by the traversing gear in the trail. Sighting was, of course, indirect, the sighting point being a staff planted in the ground beyond the rear edge of the pit. Firing was by lanyard, the man pulling it sometimes standing on the ground and sometimes remaining astride of one cheek of the carriage and taking a short hold on the lanyard.

The recoil of the gun is about 4 ft., and it moved back and forth easily without jar. Careful observation of the spade failed to disclose any visible motion. As the battery was fired at ranges from 7,600 to 7,800 m. (8,311 to 8,530 yards), the elevation was considerable, apparently about 40 deg. The high elevation, as well as the firm stony ground of the quarry, were both favorable to checking horizontal motion. It should be stated here that the cradle has two recoil cylinders and two return cylinders, one each above and below, and surprisingly small for so powerful piece of ordnance. A slight splinter-proof shield is also attached to the front of the carriage.

Fire control was from captive balloons and possibly also from a land station as it was stated that fire was being observed from three points. After each shot the results were telephoned to each gun, there being a telephone station between the guns. The blast effects were considerable, but not disagreeable to observers standing on the edge of the quarry pit in rear and about 80 ft. from the guns. The roof coverings of the buildings of the cement mill, located about 150 ft. in front, were lifted and dislodged. The battery fired seven shots in 29½ minutes by actual timing, counting from the first shot. There was not a single hitch or delay with either piece, although this was the first time the battery had been fired in the field, it being entirely new and fresh from the Krupp works at Essen.

Weights

The weights of the loaded wagons vary somewhat, but average about 15 tons. The motor tractors also vary, those of wagon No. 1 being the heaviest, and also weighing about 15 tons. On fairly good and level roads the battery travels about 10 km. per hour.—*Journal of the United States Artillery.*

Where His Brother Was.—A poor boy of wretched appearance, and apparently of about ten years of age, was recently brought before a Scotch magistrate charged with causing an obstruction by playing football in the street.

"Can your father not clothe you decently?" asked His Honor, surveying the bundle of rags with a look of profound disgust.

"Ma faither's dead," replied the culprit sobbing bitterly.

"But you have some friends, surely?" persisted the Magistrate.

"I hae a brither."

"Where is he?"

"He's in the University Museum."

"Is he in a situation there?"

"Na, he's in a bottle there," was the unexpected reply. "He was born wi' two heids."

Observations on Safety Valves for Marine Boilers*

By E. F. Maas

The various elements of marine boiler safety valves which have to do with successful operation are considered. Seven typical valves are discussed and illustrated. Many suggestions of practical value for the grinding and repair of safety valves are embodied, these being the result of observations made by the author on valves under working conditions, and on repaired valves in the laboratory. The subject is pertinent to our shipbuilding revival.

THE purpose of this article is not give a complete description of the design and working of all marine safety valves to be found on the market to-day, but to analyze some of the characteristics of the working parts of the more common types, to indicate their advantages and the difficulties experienced with them, and to point out helpful methods in repairing and improving old valves. The paper presents the results of observations made on valves under working conditions and during tests of repaired valves in the mechanical laboratory. In the case of one valve, not yet upon the market, the statements are based upon experience gained from work on other valves, and on a somewhat incomplete report of laboratory tests of this valve. This test was not witnessed by the author. Each of the seven figures gives, not a complete view of a valve, but a partial section only, this section showing such parts as come within the scope of the paper. It is assumed that the working of these safety valves is familiar to every reader, as well as the nomenclature of the valve parts. No general explanation of them, therefore, is given.

Fig. 1 represents a valve of a somewhat obsolete design probably not made by any manufacturer to-day. This type

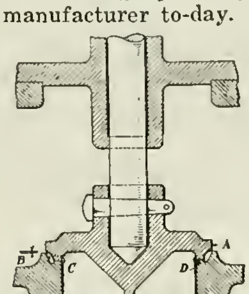


FIG. 1. OLD TYPE OF SAFETY VALVE.

is still to be found, nevertheless, in many of the older ships, and should be considered. Fig. 2 shows a later type of valve having an attachment for adjusting the blow-down, a feature indispensable in a modern marine safety valve. Fig. 3 is practically the same as Fig. 2, the main difference between the two being in the design of the blow-down adjustment. Fig. 4 represents one of the latest and most successful designs on the market at the present time. In Fig. 5 is shown a valve which has not yet fully emerged from the experimental stage, and to the knowledge of the author is not yet offered for sale as a marine safety valve. Figs. 6 and 7 show modifications made to valves of

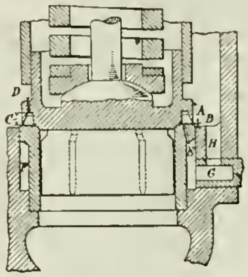

FIG. 2. LATER TYPE OF VALVE WITH ADJUSTABLE BLOW-DOWN.

the type represented by Fig. 3, these modifications having been applied during the repair of these valves in order to fit them for further service, after their original working adjustment had been destroyed through long service or neglect in maintenance. The particular features discussed in the article are:

(a)—Valve seat, flat or beveled, and its tightness.

(b)—Pop of valve, amount of simmering before pop, and height of lift.

(c)—Closure of valve and chattering at closure.

(d)—Blow-down of valve and methods of adjustment.

(e)—Discharge capacity.

(f)—Overhaul and adjustment of old valves and improvements made at slight expense.

Valve Seat

A glance at the figures will disclose two valves with flat seats (Figs. 1 and 5), the other five having beveled seats. While this might indicate that the beveled seat is the more common, the relative advantages of each type are strongly supported by manufacturers of the two types. The experience of the author has been that a flat seat is just as easy to grind-in and make tight as a beveled seat, and that the flat seat is more likely to stay tight. On account of the distortion of the valve seat which will result from a slightly uneven expansion or from spring of the material under high pressure, the tightness of a beveled seat is seriously affected, and the more so the greater the bevel, if by bevel we understand the angle between the valve seat and a plane perpendicular to the center line of the valve.

On the other hand, a flat seat will remain steam-tight even after a considerable distortion has taken place, provided that the valve has been carefully ground to its seat in the first place. It should be borne in mind that the valve and seat are in contact only along a very narrow strip, in the case of either flat or beveled seats. For equal lifts of the valves, a flat seat will give a greater discharge capacity under certain circumstances, as will be discussed later, a fact which will weigh in favor of the flat seat, for some designs, at least. It has been argued that a beveled seat, especially where the bevel is considerable, about 45 deg., will more easily rid itself of particles of scale or other foreign matter between the valve and its seat. In this connection attention should be called to the prevalent custom in marine practice of attempting to tighten the valve on its seat by turning it by means of the valve stem. Such practice usually has an effect directly opposite to that desired. A better way is to lift the valve from its seat by the easing gear and thus blow away the scale or other matter. A steeper bevel than 45 deg. is inadvisable for a steam safety valve, as the tendency for the valve to stick on its seat is too great and may produce disastrous results. It is significant that while only a few years ago most safety-valve specifications

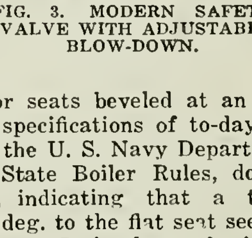

FIG. 3. MODERN SAFETY VALVE WITH ADJUSTABLE BLOW-DOWN.

called for seats beveled at an angle of 45 deg., specifications of to-day, notably those of the U. S. Navy Department and various State Boiler Rules, do not require it, indicating that a transition from 45 deg. to the flat seat seems to be under way. It is the author's opinion that such a change is for the better.

Pop of Valve

By "pop" of a safety valve is meant its instantaneous rise to almost full lift after the first tendency to move from its seat, or what is known as simmering,

*From a paper presented before the American Society of Mechanical Engineers, New York, December, 1916.

has taken place. A clean-cut pop is most vitally necessary in a successful safety valve. Without pop there will be a prolonged simmering of the valve as soon as the pressure has been reached for which the valve has been set, and the unduly prolonged simmering will soon score both valve and seat, particularly if the steam is superheated, thus producing a leaky valve. The pop of the valve in Fig. 1 will be determined by the diameter of the flange A, the amount of the distance B, and, to some extent, by the shape of the surface C. It is assumed, of course, that the valve has been ground to its seat and made tight. To design a valve of this type that will give a satisfactory pop, therefore, requires previous experience regarding the relations of these three variables, otherwise some experimenting must be done. When this valve is refaced and reground, it is also of utmost importance that the original conditions of the working parts be restored. Gauges for the original shape of both valve and seat, and the proper distance between the two, should be furnished the machinist repairing the valve, otherwise a misfit is liable to result and an uneconomical valve produced. A valve of this type requires a very long spring in order to give a satisfactory lift, on account of the small overhang of the flange A over the seating surface of the valve D, which limits the available additional lifting force required after the valve has started from its seat.

In the valve in Fig. 2, the pop will depend on the diameter of the flange A, the amount of the distance B, the depth C of the main pop chamber, and the size and number of the holes D. Of these four items, A and D are determined by the manufacturer of the valve, and, if rightly proportioned in the first place, need never be changed. Items B and C are both variable, however, with the wear and refacing of the valve and seat. In this valve it is desirable to have the lip A wear down in the same proportion as the valve and seat. As this is very seldom the case, however, there arises the necessity for adjusting these features when the valve is overhauled. It should be noted that the depth of the pop chamber does not influence the pop as much as does the distance between the flange lip and the valve bushing. The former need be checked only roughly, while the distance B must be absolutely correct. An approximate value for B is 0.01 in. for the average size of marine safety valve.

The pop in Figs. 3 and 6 is decided by the three items, size of flange A, distance B and depth of pop chamber C. In these respects the valves are similar to the valve of Fig. 2, the remarks about which will apply to Figs. 3 and 6. One difference, and an important one, is that the distance B can be adjusted after the valves are assembled, by means of the blow-down ring D. Thus, it would seem as if the necessity for the very close machining of the lip A in overhauling these valves would not exist. Such is not always the case, however, as the adjustment of the distance B for a satisfactory pop may interfere with the adjustment for the desired blow-down. This will be explained in more detail later.

In the valves of Figs. 4 and 7, the pop is dependent upon the size of the flange A, the distance between flange and

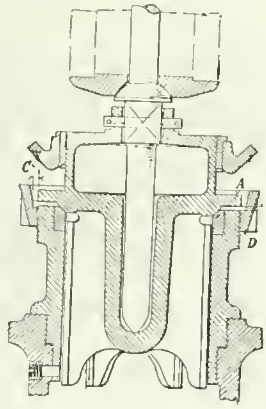

FIG. 4. RECENT TYPE OF MARINE SAFETY VALVE.

valve seat B, and the width of the ring-shaped opening at C. This difference between the two valves prevails, however, that in Fig 4 the main deciding feature is the distance B, by reason of holding the ring area C comparatively large, whereas, in Fig. 7, the pop will be determined mainly by the distance C, which is just large enough to let the valve flange A clear the inside of the adjusting ring D. Therefore, in overhauling the valve of Fig. 4, strict attention must be paid to the distance B in order to bring it back to its original value, by means of a cut from the wider side of flange A in case either the valve or its seat have been refaced, thereby lowering the valve and decreasing the distance B. In the valve of Fig. 7 only a rough check of distance B need be made. A suitable valve for this distance in an average-size valve is 3/16 in. The width of the ring area C has been fixed once in making the valve parts, and need never be changed in overhauling this valve.

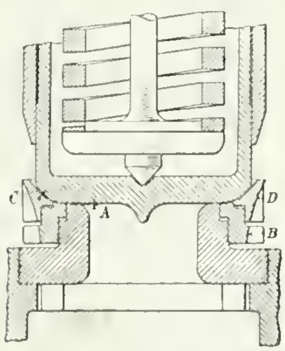

FIG. 5. EXPERIMENTAL VALVE.

In Fig. 5, the pop depends upon the distances A and C, which can be regulated by means of the adjusting rings B and D. The inner ring should be screwed very close to the valve disc, but not touching it. The outer ring furnishes the greater part of the additional lifting force required after the valve has started from its seat.

Simmering

The reduction to a minimum of the period of simmering before lift, which is very essential to the successful working of any safety valve and to the length of its useful life, can easily be accomplished in all the valves of Figs. 3 to 7 if the proper care is exercised. In the valves of Figs. 1 and 2, as previously pointed out, the reduction of the simmering is mainly a question of design and original adjustment, unalterable after the valve has been set up.

Lift

It is known that all safety valves will give their highest lift at popping, the sustained lift being less than this by from 10 to 25 per cent.. The average lift of a 3-in. or 4-in. valve is about 1/8 in. To increase this lift without interfering with the blow-down or resorting to abnormally long springs is a difficult matter. In order to obtain the maximum lift, the valve spring should be made to contain as many turns as possible within the space available for it.

Closure

In order to prolong the life of a safety valve, it is necessary that its closure be accomplished with the minimum amount of shock. When a valve comes down on its seat each time with a heavy blow, both valve and seat will soon be distorted, and the valve will start to leak. For obtaining a large discharge capacity, a high lift is desirable, but this becomes a detriment if the closure is accompanied by shock. In this respect a valve with a beveled seat is generally inferior to the one with a flat seat, as the flat seat affords more of an opportunity for the steam to form a cushion at the moment of closure. Especially is this the case with the valve shown in Fig. 5, there being an excellent steam cushion between the valve disc and the inner ring B for checking the descent of the valve. Another valve which seems to give an easy closure, although having a 45-deg. beveled seat, is the one shown in Fig. 7. It is to be regretted that on neither of these valves are there available data on the length of their useful service without repairs upon which to base a more reliable conclusion regarding this feature of the valve closure. As previously mentioned, both of these are new types of valves and not yet fully tested out in service. The tendency of a valve to chatter at closure is generally caused by too small a blow-down.

Blow-down

For adjusting the blow-down, or difference in steam pressure under the valve at popping and at closure, there are two different systems represented in the valves shown. Before analyzing these two systems, it should be mentioned that in the valve of Fig. 1 there is no adjustment of the blow-down. In this valve, therefore, the amount of blow-down desired will have to be decided on in advance, by previous experience from similar valves, proportioning the valve flange and the spring as well as the shapes of valve and seat so as to give the desired blow-down.

The arrangement in the valve of Fig. 2 for adjusting the blow-down is one probably familiar to most steam engineers. When this valve discharges, part of the steam passes through the holes E drilled in the bushing and into the chamber F, generally termed the secondary pop chamber, but more properly called the blow-down chamber. The only exit from this chamber is through the bushing G and the passage H communicating with the discharge space of the valve casing. By turning the bushing G and locking it in different positions, the size of this exit passage for the steam can be restricted, thereby limiting the amount of steam passing through the holes E, and so regulating the pressure under the valve lip A. Of course, the holes D in the valve flange will have a similar influence on the blow-down. The size and number of these holes are generally proportioned for a minimum blow-down of, say, 4 lbs. A smaller blow-down than this should not be attempted in any safety valve as it only shortens the life of the valve and produces a tendency to chattering, as previously mentioned, with no additional advantages in the working of the valve.

In all of the valves of Figs. 3 to 7, the adjustment of the blow-down is accomplished by means of the adjusting rings D. Screwing these rings up will increase the blow-down and screwing them down decreases it. The shapes of these rings should be noticed. The rings of Figs. 4 and 5 are especially adapted to give a minimum obstruction to the flow of steam and so increase the discharge capacity of the valve, both being excellent shapes. It has been especially claimed for the ring of Fig. 5 that in conjunction with the lower ring B it has the effect of reducing the lifting force at very low lifts and increasing it as the lift increases. This is a most desirable feature in any safety valve.

The ring D of Fig. 7 has been designed and tried out as an improvement on valves of the type shown in Figs. 3 and 6. It has already been pointed out that in these valves the main feature determining the pop is the distance B, also that the position of the ring D will determine the amount of the blow-down. Thus it will be seen that there are two factors to be considered in determining the proper position of these adjusting rings, and that each of these factors may require a different setting of the ring. In such a case it is necessary to take out the valve disc and machine its lip A until the proper distance of this lip over the adjusting ring is obtained, after first determining the position of the adjusting ring for the desired blow-down. This procedure involves tedious trials.

Where gauges for finishing the valve disc and adjusting ring are furnished by the manufacturer of the valve, it is comparatively easy matter to machine these parts when making repairs. When the time comes, however, to overhaul the valve, it is generally found that all gauges are lost or unavailable. In order to eliminate the tedious machine work in overhauling and adjusting valves like those in Figs. 3 and 6, the modifications as shown in Fig. 7 were devised. The lip of the valve disc has

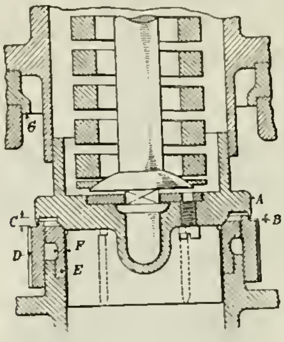

FIG. 6. MODIFIED SAFETY VALVE OF TYPE 3.

been cut away and the diameter of flange slightly reduced. The shape of the blow-down ring has been changed entirely, as shown, and made somewhat similar to the one in Fig. 4. The different action of the two rings D in Figs. 4 and 7 as regards popping has already been explained. The main feature in the ring of Fig. 7 determining the blow-down is the angle E. This angle, 36 deg., 30 min., has been found to give a range of blow-down of from 4 to 9 lbs. The laboratory tests on the popping and blow-down of this improved valve have given very good results.

Discharge Capacity

It is well known that when steam under pressure is allowed to flow through an opening, the maximum discharge will be obtained when the lower pressure is equal to or less than 58 per cent. of the higher pressure. When such conditions obtain, the pressure at the throat section, or most contracted part of the channel through which the steam is flowing, will be 58 per cent. of the higher pressure, regardless of how much the pressure in the discharge chamber will fall below this value. The weight of steam discharged can then be calculated from Napier's formula: Flow in pounds per second = absolute pressure $\times$ area in square inches $\div$ 70. If this is applied to the safety valves shown in Figs. 1 to 7, it will be found that the valves of Figs. 1, 2, 4, 5, and 7 undoubtedly will

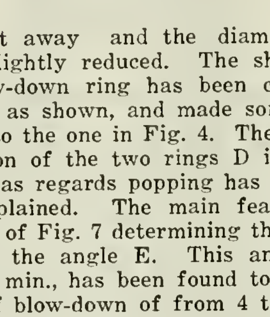

FIG. 7. ANOTHER MODIFIED VALVE OF TYPE 3.

have their throat section at the inner circumference of the valve seat. Therefore, the area of opening at this section will determine the discharge capacity of the valve, provided the resistance to the flow is not made great enough to raise the pressure in the valve casing above 58 per cent. of the pressure under the valve seat. Making allowances for reductions of the free opening over the valve seat caused by guide wings, the following approximate formulæ, as given by some manufacturers, are obtained for calculating the discharge capacity:

$W = 149$ lpd for a flat seat
$W = 105$ lpd. for a 45-deg. seat

where W = discharge in pounds per hour
l = lift of valve in inches
p = absolute pressure under valve, lb. per sq. in.
d = diameter of valve seat in inches.

For equal lifts, then, the flat seat will give a greater discharge than the 45-deg. seat, which is obvious when it is considered how the 45-deg. seat restricts the throat section of the valve as compared to the flat seat. It should be mentioned here that the discharge capacity will be influenced to some extent by the smoothness of the approach to the throat section. On this account, the valve of Fig. 5 should give an exceptionally good discharge capacity, which seems to be borne out by the meagre test figures available. With valves of the shape shown in Figs. 3 and 6, it is frequently found that the actual discharge capacity will fall considerably below that obtained by the above calculations. This, no doubt, can be accounted for by the throttling of the discharge channel under the valve lips, especially at the lower lifts.

Repair and Adjustment

Bearing in mind that a safety valve, to be successful and satisfactory, must not have too delicate an adjustment nor require too frequent overhauling, it seems advisable to alter the valve in Fig. 3 to the type shown in Fig. 7, where repeated attempts at obtaining satisfactory operation of the old type have failed. Such alteration can be accomplished easily and cheaply, as the only new part to be made is the adjusting ring D, and the only part to be machined is the valve disk. The result will be an exceptionally rugged valve having no delicate parts, and one which can be easily overhauled and adjusted without expert assistance.

Grinding

For grinding a valve to its seat the most satisfactory grinding material is powdered glass and machine oil. It is easiest and most expedient to grind a valve cold, and this will in most cases produce entirely satisfactory results. Only where repeated efforts at making a valve tight by these methods have failed, should hot grinding be attempted. The hot grinding is a trying performance to any workman, and will only be an approximation to actual working conditions in any event, as a grinding at the actual temperature under which a safety valve operates is out of the question. Where all other methods have failed to produce a tight valve, the design shown in Fig. 6 will sometimes serve. By inserting the raised seat E and taking care to machine this so that its weakest section F will be between the old valve seat and the new, there is an opportunity for this raised seat to adjust itself to the valve, regardless of what expansions and contractions may be taking place in the metal of the old valve seat. Frequently this will produce a tight valve. The construction shown in Fig. 6 is an improvement on the valve shown in Fig. 3, but the same, or a similar design, can be applied equally well to most other types. In making this alteration to a valve it is necessary to have a new valve seat E and adjusting ring D, and to insert a distance piece G under the valve bonnet in order to raise the bonnet the same amount the valve has been raised from its former seat. The author has seen this method applied frequently and with great success.

Another point, often misunderstood in repairing a safety valve, is the amount of clearance to give to the guide wings under the valve disk in the valve bore. No attempt at a very close fit of these parts should be made, as such would only increase the chances of the valve sticking. A suitable clearance for a 4½-in. valve bore is 1-32 in. on the diameter, or 1-64 in. on each side.

HEATING BY STEAM AT DIFFERENT PRESSURES

RECENTLY in Chicago tests were made to determine the relative cost of heating with steam at atmospheric pressure as against 3 to 5 lb. pressure in modern office-building plants. In an analysis of the problem a heat requirement of 5,000 B.t.u. per hour was taken. On the whole, it appears that there is no appreciable difference in cost in heating at different pressures. There is, however, an advantage in higher pressure from the standpoint of first cost of plant, because as the pressure is greater the plant may be smaller. This factor, however, has a limited value in practice unless excessive pressures are used. As a matter of fact, any plant designed to work at 5 lbs. should have margin enough to work perfectly at atmosphere, and vice versa, so that in the end the cost of heating will be identical in both cases.

ADVANTAGES OF ECONOMIZERS

BOILER plant efficiency can be considerably increased by adding economizers, which are used in most European plants, but find little favor in this country. The objections ordinarily offered are:—Their initial cost; reduction of available draft and, in many plants, necessity of installing mechanical-draft systems; cheap fuel (speaking comparatively); low load factors; complication of the power-plant outlay.

The chief reason that they are not used more generally is that their value is not realized. It is difficult to reason out just what effect load variations have upon an economizer as a heat absorber. If plants were operated continuously for 10 or 12 hours and completely shut down the rest of the time, the saving would be in proportion to the load factor, but where the load remains on, and only varies from overload to underload, the value is difficult to determine. Since however, such plants are ordinarily operated uneconomically at both high and low loads, and since economizers are of greater value the lower the boiler efficiency, they are particularly needed in plants having variable loads, and the saving in fuel, if not more, will be at least proportional to the load factor. Much depends upon properly proportioning the installation, and, therefore, before an economizer is decided upon, a plant must be closely studied and the governing factors, such as flue-gas temperature, feed-water tempperature, weight of air per pound of coal, load factor, character of load, etc., very closely predetermined.

UTILIZING EXHAUST STEAM

THE value of exhaust steam for heating and the consequent saving effected has been demonstrated, and many plants take advantage of it, but the practice should be more general. Even plants operating condensing could bleed the low-pressure receiver of a compound engine or the low-pressure stages of steam turbines and distribute this steam through the buildings. In power plants where economizers are not employed and the temperature of the water is low when fed into the boilers, this partly expanded steam could also be used to advantage in feed-water heaters.

In plants where large quantities of low-pressure steam are required and the pressure cannot be expansively reduced in a cylinder or turbine, a saving still could be made by generating this steam in a boiler under low pressure. It has been experimentally determined that there is about 6 per cent. difference in boiler efficiency between generating steam at near atmospheric pressure and at 350 degs. Fah., because of the increased temperature difference between the furnace gas and the boiler water, greater heat absorption and consequently lower flue-gas temperatures.

REDUCIBLE LOSSES IN POWER PLANTS

THE greatest and most neglected loss in the average boiler plant is from excess air. The magnitude of this loss at different CO_2 percentages is applicable to any fuel, liquid, solid, or gaseous, if its available hydrogen percentage is known. The impression prevails that coal must be burned with about 50 per cent. of excess air. Some authorities claim that going beyond 10 to 12 per cent CO_2 the loss due to incomplete combustion will offset the saving effected by reducing the excess air. This opinion is based upon certain types of installation only, and should not be accepted and disseminated as a general condition. Some few up-to-date plants are averaging 17 per cent. CO_2 with bituminous coal, without serious losses due to incomplete combustion.

One objection to high CO_2 is the extremely high furnace temperature and consequent rapid depreciation of furnace linings. For this reason many maintain 10 per cent. CO_2 as the maximum. With low percentages of excess air, proper design of combustion space becomes much more important to prevent incomplete combustion and too high furnace temperatures. Exceedingly high furnace temperatures have no real advantage and several disadvantages, therefore heating surface exposed directly to the fuel bed to reduce the furnace temperature will not only cause a decrease of the slagging effect upon the firebrick, and thus increase the CO_2 possible to maintain, but will also increase the efficiency of the boiler due to the heat radiated directly to it, and will increase the boiler capacity without increasing the flue-gas temperature. With a proper furnace volume, smoke will not form if provisions for gas mixing are maintained and the temperature does not drop off too low or the boiler is not forced too much. Velocity of gas, time of contact, and hydraulic mean depth are important and deserve thorough study under all conditions of installation. Not much is being done in this direction and quite large boiler builders ignore the matter altogether.

Boilers can be operated at two times their rating, and more, but not economically unless designed for it; with the rates of heat absorption obtained at present in most installations, if operated at very high ratings the loss will be too great, unless the temperature of the escaping gases be reduced in economizers. The increase of velocity will cause draft loss, but this is not so serious, for the necessity of installing mechanical draft brings other advantages. With high ratings and high velocities the power required to produce the draft becomes of interest. Fear that so much of the steam generated will be required to produce the draft that the advantages obtained will be offset is unfounded, if the blower is designed for efficient work and driven by an efficient engine or motor.

It is a bad practice to fasten zinc-iron sheets together with iron or steel rivets. These soon rust if not painted, and the rust penetrates through the edges of the iron encircling the rivets, and thus proves disastrous. Only zinc, or zinc-covered rivets, should be so used.

Zinc is ductile between 212 degs. Fah. and 302 degs. Fah., and can then be shaped as required; but when either above or below these limits it becomes brittle and unpliant, and, therefore, not adapted for treatment. It melts at about 786 degs. Fah., if volatilization is guarded against.

PROGRESS IN NEW EQUIPMENT

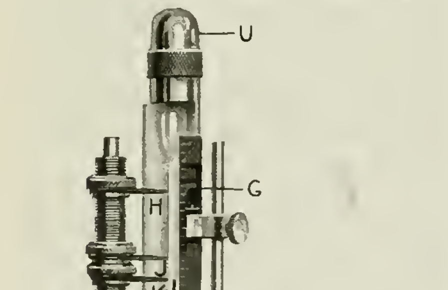
A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

FLUID GAUGE FOR MEASURING WORK

MODERN requirements regarding the quick and accurate gauging or measuring of articles in course of manufacture have created a demand for a measuring device of an entirely different nature from micrometers and gauges. Despite the accuracy by gauges and micrometers, their liability to wear prevents them from remaining accurate for any great length of time under continuous use, in addition to which are errors due to the touch of the operator and degree of skill required.

The Prestwich Fluid Gauge has been developed as the result of long experience of these troubles, and by it articles can be very accurately and quickly gauged without skill or sense of touch on the part of the operator. It is not subject to wear, and with ordinary care will remain accurate indefinitely.

The instrument consists of a fluid-con-



FLUID GAUGE FOR MEASURING WORK.

taining chamber "A," having a flexible diaphragm "B," a glass tube "C" of fine bore, which is connected with the chamber "A," means for indicating the dimensions of the piece, and means for correcting for variations of temperature. The diaphragm "B" is provided with a hardened steel anvil "D." The article to be measured or gauged is passed between this anvil "D" and fixed anvil "E." Any pressure on the anvil "D" causes the fluid to rise in the glass tube "C." The chamber "A" is provided with a thread and micrometer index and pointer on the upper surface to indicate thousandths of an inch (or one-hundredths of a millimetre).

The carrier "F" is provided with a scale "G" and three adjustable pointers "H," "J," "K," the scale being divided to indicate ten-thousandths of an inch (or one-thousandths of a millemetre). The two top pointers "H," "J" indicate the tolerance limits it is desired to work to. The bottom pointer "K" is set to the normal level of the fluid in the glass tube "C." The carrier "F" is adjusted by the thumb nut "S" to keep the bottom pointer "K" level with the normal level of the fluid, and thus compensates for variations of temperature.

The instrument is roughly set by rack "M" and pinion "N" on the pillar "O" to suit the article, the clamping screw "P" then tightened up and the final adjustment made by the micrometer adjustment to a standard gauge or piece of known dimensions. A displacement of the diaphragm "B" causes a displacement of the level of the fluid in the tube "C" relative to their respective areas. Any variation in the size of pieces passed under the gauge is indicated by the difference in the height the level rises in the glass tube.

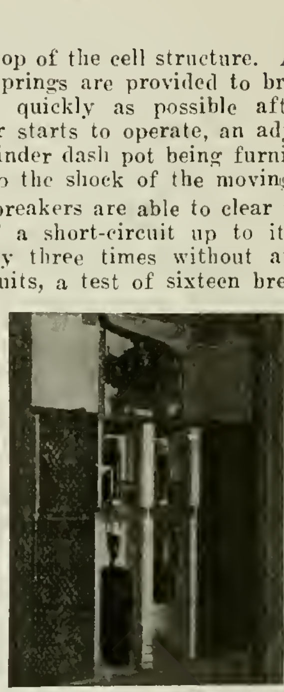
This apparatus is placed on the market by the Coats Machine Tool Co., New York.

CELL MOUNTING OIL CIRCUIT BREAKER

A COMPLETE line of oil circuit breakers has been recently developed by the Westinghouse Electric & Mfg. Co., East Pittsburgh, two of which, types E6 and E7, range in capacities from 300 to 1,200 amps. at 23,000 volts, and from 1,600 to 2,000 amps. at 16,500 volts. The former is for cell mounting, as illustrated in the accompanying engraving, while the latter is for wall or pipe mounting. All steel construction is used, thus providing apparatus which is exceptionally compact for its rupturing capacity, which ranges from 35,000 to 40,000 kva. at maximum rated voltage, with proportionately higher capacities for lower voltages.

For cell mounting, a novel feature is the holding of the steel base of each pole unit in channel irons built into the cell walls, whereby the units are easily slid in and out; the single pole solenoid complete with its mechanism, is mounted on top of the cell structure. Accelerating springs are provided to break the arc as quickly as possible after the breaker starts to operate, an adjustable air cylinder dash pot being furnished to take up the shock of the moving parts.

All breakers are able to clear the system of a short-circuit up to its rated capacity three times without attention to circuits, a test of sixteen breaks be-



ing made on a 25,000 kva., 23,000 volt turbo-generator circuit, without the breaker being opened for change of arcs.

SHIP BAND SAW

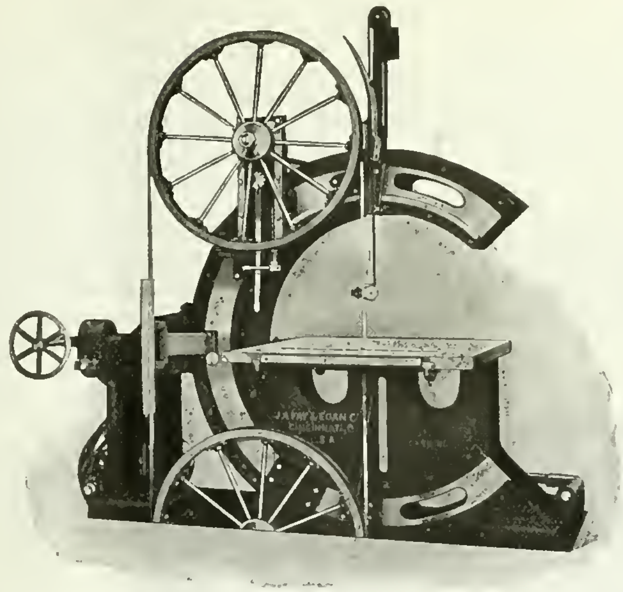
THE revival of wooden shipbuilding has created a demand for numerous items of equipment possessing more or less novel features of construction, and the machine shown in the engraving herewith has been designed and built by J. A. Fay & Egan Co., Cincinnati, O., for the purpose of working the extra large timbers required in the construction of ocean going vessels.

This machine is designed for extra heavy band sawing, both straight and curved, and while particularly applicable to shipwork can also be used to advantage in railroad and bridge shops, heavy vehicle work, and lumber mills. It saws to any angle in a full semi-circle, the wheels being carried on a housing mounted on roller bearings and angling 45 deg. to right or left by power, with handwheel adjustment for extremely fine setting.

Column is a single casting of ample weight with broad floor bases which enable it to carry the wheels at any angle without vibration. An auxiliary column at the rear carries the angling mechanism, and the face of the main column is planed and fitted with roller bearings to carry saw carriages, guides, etc. The table measures 48 in. x 48 in. and is all iron, and mounted perfectly rigid on main column and always level.

The wheels are 48 in. dia. x 3 in. face, and carry blades up to 3½ in. wide. They are steel spoked with laminated wood rims, faced with rubber, and are mounted in self-aligning ball bearings. Both wheels are mounted on a heavy circular carriage, gibbed to the main frame and traveling on self-lubricating roller bearings mounted in main column, making angling adjustment quick, easy and extremely close. The wheels move simultaneously, and are so located in relation to the carriage that the blade angles from the point where it passes through the table.

Driving gear is provided with automatic take-up to maintain proper tension on belt at any angle. A 15 horse-power motor at 1,500 to 1,800 rev. per min. can be belted to main driving pulley, or if at 350 rev. per min. can be direct coupled to drive shaft.

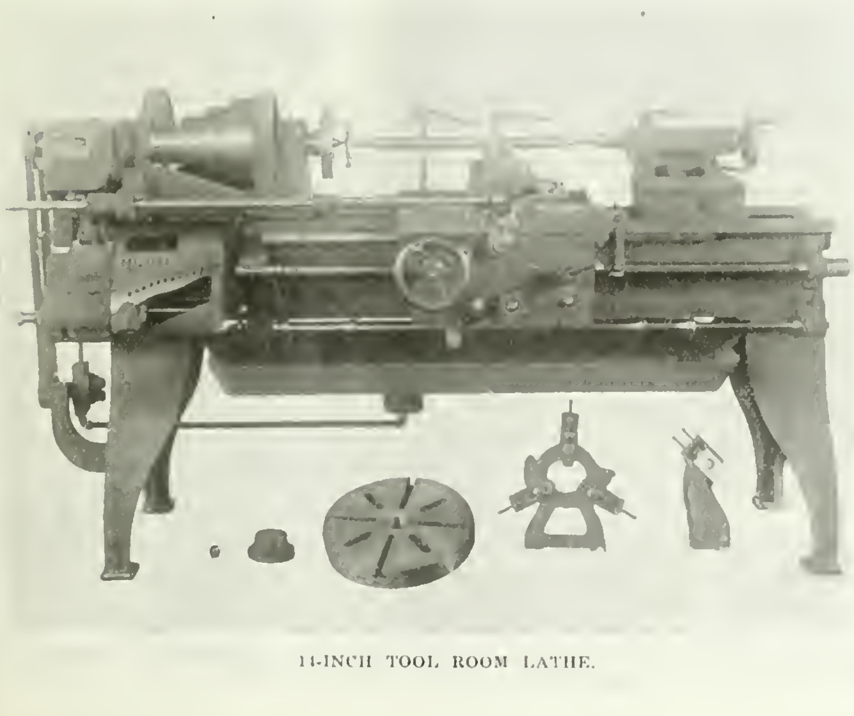


BAND SAW WITH ANGULAR ADJUSTMENT FOR CUTTING SHIPS TIMBER.

14 IN. TOOL ROOM LATHE

THE machine shown in the accompanying engraving is the most recent design of tool room lathe placed on the market by the Cincinnati Iron & Steel Co., Cincinnati. These lathes which bear the trade name of Cisco are of 14 in. capacity and of the four-step cone pulley type with back gearing. The machine as illustrated is equipped with lubricating pump, pan, taper attachment, and relieving attachment in addition to regular equipment. The pump is mounted on a bracket fastened to the cross web of leg casting under headstock, and is driven by belt from a pulley on the tail end of the lathe spindle. The relieving attachment is gear driven from the spindle, with sliding drive shaft placed along the front of headstock. A bracket on the side of carriage supports the end of the shaft so that the jointed section next to the compound rest may function properly, one of the universal joints being of the telescopic type so that angular adjustment of the compound rest may be made at any time.

Automatic stop, thread stop and tool tray are regularly fitted to these lathes, the stops being operated by stop lock at bottom of apron. A quick change feed box is incorporated in the design. Draw-in collet chuck is supplied when specified, while face-plate steady rest, back rest and necessary change gears are supplied as illustrated.



14-INCH TOOL ROOM LATHE.

COMBUSTION IN HAND-FIRED FURNACES

THE fuel in most types of furnaces acts primarily as a gas producer. With a 6-inch fuel bed the oxygen in the air rising through the grate is all used up in combustion in the first 4 inches from the grate. At a distance of 4 inches from the grate the carbon dioxide content of the gases has reached or passed a maximum of 10 to 16 per cent. and begins to drop. At the surface of the fuel bed the gases contain no oxygen, only 6 to 8 per cent. of carbon dioxide and 20 to 32 per cent. of combustible gases. The composition of the gases is practically independent of the rate of air supply. The larger the quantity of air forced through the fuel bed, the faster the fuel burns or gasifies, but the ratio between weight of air supplied and weight of fuel burned remains constant at about 7 to 1. In general the temperature in the fuel bed is the highest at 3 to 5 inches from the grate, which is also the point of maximum carbon dioxide content.

Fuel Bed Thickness

As most of the oxygen is consumed in the first 4 inches of the fuel bed, it is not necessary with the ordinary rates of combustion to run a fuel bed thicker than 4 to 6 inches in order to obtain a high carbon dioxide and a low oxygen content in the flue gases. The rate of combustion or gasification of coal depends on the amount of air that can be passed through the fuel bed. The thicker the fuel bed the higher is its resistance to flow of air through it and the less air can be passed through with a given chimney draft. A thick fuel bed, therefore, reduces the rate of combustion and thus reduces the capacity of the boiler.

A thick fuel bed is further undesirable because it increases the tendency of the coal to form troublesome clinker. Perhaps the only apparently defendable excuse for carrying a thick fuel bed is the fact that the chances of burning holes in the fuel bed are reduced. A skillful fireman avoids holes in the fuel bed by firing frequently and placing coal on the thin spots. A claim that fuel beds can not be kept in good condition if carried thin is a confession of neglect and lack of skill. A fuel bed is understood to be only the layer of incandescent and freshly fired fuel and does not include the layer of dead ashes and clinker on the grate. The ash fuses in the upper layers of the fuel bed, and as it sinks it solidifies 2 to 4 inches from the grate.

As at the surface of the fuel bed the gases contain 20 to 32 per cent. combustile gas and practically no free oxygen, to obtain complete combustion additional air must be introduced over the fuel bed. This statement is true of all the fuels, including coke, tested by the Bureau of Mines, Washington, D.C. As a general statement, about one-half of the 15 pounds of air used to burn 1 pound of coal in a boiler furnace is supplied through the fuel bed; the other half must be supplied over the fuel bed.

OUR SHELL INDUSTRY EBBING

NOTWITHSTANDING the fact that the munitions industry in Canada has long ago outstripped in scope and proportions the most substantial of those to which we pinned our faith in pre-war days, it has never been believed but that a modicum — if even that much, of the activity now in progress would retain a permanent value. The various plants created by our own and the Imperial Governments will doubtless be permanently preserved on a production footing, the extent of which will be largely governed by the status of the peace arrangements, the definiteness of the security against an early or late future repetition of this three-year tragedy, and the decision to maintain, or otherwise, the condition of preparedness now so well and fully established.

Although, generally speaking, the end of Canada's munition industry is by no means in sight, evidences are not wanting that some considerable curtailment of shell-making activities may be said to be at least imminent if not already operative. Attention has been drawn in these columns on several occasions during the past year or more to the extraordinary degree of development output being procured from Britain's specially created and equipped National shell factories, as also to the possibilities that, in spite of the necessary prodigal expenditure of shell in bending "Hindy's" line at least back to the Rhine before the snow flies in the coming winter, the bulk of the Allied requirements would be met within the Motherland borders. Such a consummation has, we believe, now been achieved, and, as a consequence, further or repeat orders for 8 in. and 9.2 in. high explosive shell are likely to be restricted in both number and quantity. We understand that the 60-pdr. projectile, a small number of which, comparatively speaking, have been produced here, is also likely to be eliminated.

It must be admitted, however, notwithstanding our awakeness to the fact of shell making being a transient and temporary industry, that even the beginnings of parting with it as above indicated may for the time being disturb the even tenor of our metal-working plants routine here and there. On the other hand we have much cause for thankful appreciation of the progress being made by our men in the field, besides having the consciousness that they are equipped and to spare, and that maintenance in both respects is assured right close to their spheres of action.

Another phase of the situation, and by no means an unimportant one, is that of the relief for the carrying of food supplies, of ships, otherwise engaged in transporting big shells across the Atlantic with its swarming dangers from enemy submarines and mines. It should be a source of much satisfaction to us, rather than otherwise, bearing in mind our gigantic vessel losses, and the acuteness of the food situation in the Motherland arising therefrom, that the efforts of her munitions-making army, the larger proportion of which is female-constituted, have, to even the extent indicated, relieved a growing menace to our Empire health and war activities. We in Canada have not as yet felt the pinch of lack of food, although in other respects we have profited as well as lost along with the people of Britain, and, in the apparently gradual ebbing away now of orders for the bigger shells, we may possibly still have an advantage in the readjustment following the Peace Declaration. No let-up is in sight so far as we can gather, with respect to continued activity in the other sizes and type of shell, to the generous output of which the great bulk of our metal-working plants are still contributing, and of whose individual features it is unnecessary to make a detailed reference here.

THE SHIPBUILDING SITUATION

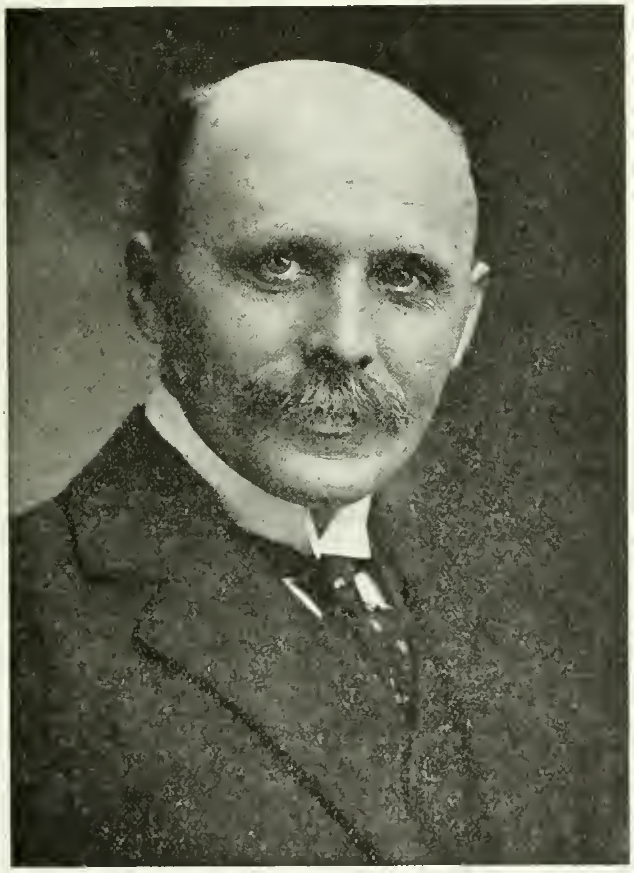
A GOOD deal of enthusiasm has been aroused not only among interests closely related to the twin crafts of shipbuilding and marine engineering, but among those more or less indirectly concerned, because of the fact that in both these spheres of industrial endeavor, our plant capacities are more or less taxed with orders—in a word, there is quite a little boom on. The foregoing is true of both wood and steel construction, although the latter easily predominates. Some misconception is, however, abroad as to the direction of effort and scope of the meantime activity. Aside from a little vessel construction to the order of private individuals or shipping corporations, both the British and Canadian Governments through their accredited representatives—the Imperial Munitions Board on the one hand and J. W. Norcross, vice-president and managing director of the Canada Steamship Lines, on the other—have placed various contracts, the former for ocean-going freighters and the latter for a type of craft whose service will be more or less confined to ocean coastal waters.

As regards the coasting vessels, quite a fleet has been ordered, and in view of the circumstance that completion and delivery of all are required within some six months' time, it may perhaps be unnecessary to state that hulls and machinery are well advanced in construction in not a few instances. Delivery on the ocean-going freighters, orders for which have for the most part already been placed, is called for by mid-Autumn, 1918.

We had hoped that some definite action towards the production of ship and boiler plate would have been taken by one or other of our large steel interests ere this, but notwithstanding rumors to that effect, no move has been made in the direction indicated; as a matter of fact we are apparently further away than ever from being in a position to meet, at least, our own needs in ship and boiler plate, and that in normal circumstances. Shipbuilding within our borders to be robust must, of course, be subsidized in some form or other, and until some steps are taken to so encourage it, the plate mill essential is likely to remain a dream.

INDUSTRIAL NOTABILITIES

COLONEL DAVID CARNEGIE, member Imperial Munitions Board and ordnance advisor, Ottawa, Canada; consulting technical ordance advisor to Department of Militia and Defence, Canada, was born at Aberdeen, Scotland, 1868, son of David and Margaret Carnegie, of Aberdeen, and received his education at Gordon's College, Aberdeen, and Royal College of Science and Royal School of Mines, London, England. On the completion of his apprenticeship to mechanical engineering at Aberdeen, 1887, he engaged in the manufacture of torpedoes, Royal Arsenal, Woolwich, 1887-89, and was science master, evening classes, Science and Art Department, London, 1889-91. From 1890-1902 Colonel Carnegie was in charge of projectile manufacture at Woolwich Arsenal, following which he was work's manager, Hadfield's Steel Foundry Co., Sheffield, 1902-6; consulting engineer and general manager, Samuel Osborn & Co., Sheffield, 1906-10; entered private practice as consulting engineer, London, 1911; director, Electric Steel & Metals Co., Welland, Ont., 1913, resigned, 1914.



COLONEL DAVID CARNEGIE.

During 1915, Colonel Carnegie was a member of Commission of Armaments Manufacture in Canada; and was also chairman of Commission on Copper and Zinc. He became a member of Institute Mechanical Engineers, 1893; Iron & Steel Institute, 1903; student, Institute Civil Engineers, 1890, associate member 1893, member, 1906; fellow, Royal Society, Edinburgh, 1910.

Published works include, "Liquid Steel, its Cost and Manufacture," Longman's Co., 1913; "Manufacture of Forged Steel Projectiles," 1891; "Manufacture and Efficiency of Armour Plate," 1892; "Manufacture and Efficiency of Armour Piercing Projectiles," 1903; "Results of Investigation on Manufacture of Steel in Belgium," 1910; "Report of Commission on Copper and Zinc, Canada," 1916. Colonel Carnegie has also secured several patents for manufacturing processes and designs which are now in use in different parts of the world.

In February, 1915, he was gazetted Hon. Lieut.-Colonel, Militia, Canada, being gazetted Hon .Colonel, May, 1916.

Colonel Carnegie married Frances Ellen Lloyd, daughter of Thomas Howard Lloyd, and has three sons. His club is the Rideau (Ottawa); his religion, Presbyterian; and his residences are London, Eng., and Chateau Laurier, Ottawa, Canada.

The General Market Condition and Tendency

THE upward movement in prices of steel continues in the United States in spite of the low figures fixed on the requirements of the American Government. This situation is reflected in Canada and prices of domestic steel products are advancing as well as on imported materials. The congested condition at the mills and increased demand is largely responsible for the prevailing tight situation in the steel market. The more important advances to be noted this week include plates, wrought pipe, black and galvanized sheets. Prices of pig-iron continue very firm and quotations on domestic iron are now approximately $47. This figure is entirely nominal owing to the uncertain conditions in the market. The demand for pig-iron is heavy, but the furnaces are sold up for several months and stocks are low. The coal situation is somewhat easier, although higher prices are expected. The coke market is strong and prices continue high. Prices of scrap metals are unchanged and the market dull in regard to copper and brass. The demand for steel scrap, however, is active, and higher prices are likely. Non-ferrous metals are dull, the only change to be noted is in spelter, which has declined. Copper is showing a weaker tendency and lower prices appear probable in the near future. Decline in prices of high-speed twist drills has been announced, but wood screws and rubber belting have advanced. The machine tool market is quiet and situation generally unchanged.

Montreal, Que., April 16, 1917.—The industrial situation is slowly adjusting itself to the changed conditions arising out of the recent American developments, but no material effect has yet become evident as to the direct bearing such a move will have on the trade relations of this country. With the complete adoption of definite plans, however, it is generally expected that some changes will naturally follow, although it is yet early to decide just what form these changes will take. The combined efforts of the United States Government and the Allied countries cannot have other than a beneficial effect upon general conditions, although in the abstract these conditions may appear to conflict with domestic progress. Shell activity continues at a satisfactory rate and the shipbuilding industry is also active, although somewhat handicapped by the lack of construction facilities and the pronounced scarcity of suitable ship plates. Manufacturers here are experiencing considerable difficulty in obtaining sufficient raw materials to operate at capacity, owing to the congested condition of the producing mills and the inability to secure reliable delivery.

Pig Iron.

The sensational rise in pig iron is undoubtedly the feature of the market for the week, if the continual advance can be considered as a feature. The demand for all grades of pig apparently has no end, and the excessively high prices have had no evident effect in restricting the call from consumers. The outstanding advance of the week has been that on Bessemer and forge, each being subjected to an advance of $5 per ton. The former is now quoted at $45.95 and the latter $41.95 per ton, Pittsburgh. The rise in other grades has been quite general, the composite price of pig iron being $39.56, this being $2.10 higher than last week. Conditions locally are unchanged, with Canadian quotations on the nominal basis of $46.50 per ton.

Steel.

Developments have not yet reached the stage where general conditions have been affected by the entrance of the United States into the war, and the market is consequently in a more or less unsettled condition. It is anticipated that supplies for the American government will be rushed out by several of the large mills, and will not seriously affect the delivery of material that has been on order for previous customers, although some little delay may be necessary in the shipment of the same. So far the Canadian situation has not been affected by the changed situation on the other side and dealers here do not expect that conditions will be varied to any great extent by recent or coming developments. With improved transportation facilities, the interest of the consumer has again reverted to the problem of the mills and their inability to supply the full requirements of the trade. The sold-up condition of most of the steel mills and the non-cancellation feature of contracts, makes the future of the steel industry one of extreme firmness; the activity of the shipbuilding trade throughout both Canada and the United States also adds to the present and future strength of the market. The problem of marine tonnage is becoming one of paramount importance and plate mills are experiencing the most active period in their history. Bessemer products have already shown a similar advance to that of the raw material, namely, $5 per ton; the current quotation on billets and sheet bars being $80 per ton, Pittsburgh. Wire rods on a similar advance, are now bringing $90 per ton. The Pittsburgh quotation of forging billets has for the first time attained the phenomenal figure of $100 per ton, the most recent advance being $10 per ton. These abnormal advances are the direct cause of the demands of the U.S. Government and the congested condition of the mills, but fortunately the greater number of consumers are covered by contract and recent advances will have little effect upon their current or future business. The coke situation has improved but recent developments have placed producers in a waiting position, as they will probably have to adjust their future schedule to conform with the policy of the government. Spot furnace has regained some of its lost strength, the week's advance of 50 cents bringing the current quotation back to $8.50 per ton. Owing to an apparent scarcity of prompt ferromanganese, the price has advanced to $400 per ton, this being $75 higher than a week ago. The programme of the American government in connection with shipbuilding will likely necessitate the increased output of plates for this purpose and may in consequence, temporarily effect the delivery to their consumers, so that the early prices of this commodity may be subjected to a still further advance. It is practically impossible to place orders for ship plates or tank plates and receive assurance of delivery earlier than the middle of 1918. The demand on the lighter sheets has been increased owing to probable early activity in connection with war supplies. Tin plate mills likewise are anticipating greater activity in view of the possible needs for army and other purposes. While wire products have retained a very firm and steady position for some time, early future conditions may be reflected in the fact that some of the American producers have all but withdrawn from the market, only quoting on specific inquiry from regular customers. This feature of the wire situation may be the preliminary to another advance on these products, and the week's advance on wire rods will also affect the early future of wire quotations. The sold up condition of the tube mills makes the market one where premiums can be readily secured by those mills that are able to guarantee reasonably prompt delivery. The exceedingly heavy demand for these products has placed the mills in a very strong position and orders are being placed for second quarter 1918 delivery. Producers of bolts and nuts anticipate an early readjustment of price quotations in an upward direction. The pressure on the wrought iron pipe mills is fast becoming like that of the plate mills, many of them having future orders, which run well into 1918. Dealers here report general conditions unchanged, but very firm and would not be surprised to see higher prices in various lines of steel. Supplies are now very low, and it is difficult to get material forwarded from the mills.

Metals.

Nothing has transpired to feature the metal situation and the general market conditions are unchanged; but prices, with the exception of lead, have developed a weaker tendency. Efforts on the part of the consumers to dispose of surplus metal have resulted in a weaker market. Tin is unsettled but fairly firm, but with an easier undertone. Spelter is becoming weaker on a dull market. Lead is steady and stronger locally. Antimony is quiet but firm.

> **CANADIAN GOVERNMENT PURCHASING COMMISSION**
>
> **The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.**

Copper.—Market conditions are apparently being reflected in the fact that sellers at present are more in the limelight than buyers. The situation is one where the consumers of copper are taking a marked interest in the trend of affairs, not that any definite knowledge of future conditions is the basis of their action, but more in view of these possibilities that might arise out of the recent attitude of producers, in supplying metal to the government at greatly reduced prices. This feature of an abnormal situation has created a certain degree of anxiety among those users of copper that are well supplied with metal for future use, and many of these are offering quantities of their surplus stock for sale, hoping to realize at current high prices before a possible decline takes place. Both producers and consumers appear to be playing a waiting game, the former expecting that the requirements of the trade will start a buying movement, while, on the other hand, consumers are expecting further declines on copper quotations. The present tendency is to lower levels. London reports a continued firmness, while New York is easier on an unsettled market; lake having fallen off one cent, and electro and castings 1¼c. per pound, the current quotations being 33½c, 33c, and 30c per lb. respectively. On a quiet market dealers here have declined their quotations 1½c. per lb., the prices asked being 38c. for lake and electro, and 37c. for castings.

Tin.—Despite the fact that no marked activity has taken place during the week, tin continues to maintain a very steady position, and quotations are a little stronger. It was expected that certain concessions might be made regarding the shipment of metal and the freer granting of permits to American ports, but so far nothing has been done in this connection to relieve the situation on this side of the water. Hopes are entertained, however, that some early arrangements will be made by which the available supply will be more in keeping with the requirements of the trade. A factor that has become more pronounced since the entrance of the United States into the war, is the increasing need to secure tin for canning purposes; for this, and other reasons, American consumers are anxious that better facilities be provided for the greater supply of metal that will be required for early future requirements. Higher prices feature both the London and New York markets; the latter having advanced ¼c. during the week, the nominal quotation being 55c. per lb. On a fairly active market tin has declined locally to 55c., this being ½c. lower than last week.

Spelter.—The dull period in the spelter market, followed by the recent activity on the part of producers, in seeking orders for second quarter business, has had the effect of developing a weak situation and lower prices are resulting. The demand for prompt metal is very light and not much resale spelter is available, but the movement of producers in seeking buyers has emphasized the dullness. London remains firm but New York reports a decline of ⅝c. for the week, the price now quoted being 10c. per lb. The local market is dull and weaker, having declined 1c. on the week, the current quotation being 14c. per lb.

Lead.—The market is quiet and comparatively dull, but the sold-up condition of the producers is the chief factor in maintaining this metal in its present strong position. Rumor is current that negotiations are proceeding whereby the U.S. government will be supplied by American producers at a figure greatly below that prevailing on the open market. No verification of this is at present available, but report has it that the price paid will be below 5 cents. Until the attitude of the producers is known it is very unlikely that the market will see little change from existing conditions. London and New York are both very firm, the prices quoted on the New York market being 9c. by the leading interests and 9½c. by independents. Lead is stronger here on a ¼c. advance, the price asked being 12½c. per lb.

Antimony.—This metal is quiet and prices are developing a weaker tendency. Spot metal is still scarce, but the supply is showing improvement. A decline of ½c. is noted on the New York market, the present price being 35½c. per lb. Dealers here report a quiet situation with quotations steady.

Machine Tools and Supplies.

No important developments have taken place in machine tool circles, and conditions are generally unchanged. The demand for shell-making equipment is gradually falling off, although a fair business is still carried on in filling orders for single machines of both special and standard design. To offset this situation, however, increased demand for machines for domestic purposes is an encouraging feature, and while the volume at present is not great, the outlook is encouraging. Shipbuilding prospects are developing, but no abnormal requirements have yet been called for by the machine tool builders. Dealers here are being advised daily of advances on all classes of machine equipment, and these conditions are expected to continue while the upward movement in raw materials dominates the market.

Scrap.

Owing to the uncertainty that seems to dominate the entire industrial situation the market in old materials is very unsettled, although prices are generally in a steady condition. Business is fairly brisk in all lines. New York prices on steel scraps are well maintained but quotations on old metals show a weaker tendency. Copper and brass scraps have declined locally while iron and steel has shown a slight advance; light copper is lower by 2c., being quoted at 22c.; crucible, heavy and wire, have declined 1½c., the prices quoted being 28c. per lb.; brass clippings on a decline of 1c. are quoted at 18c.; machine compositions are similarly affected, the price being 22½c.; heavy melting steel and old rails are bringing 19c., this being 2c. higher than last week; boiler plates are bringing 18c., an advance on the week of 3c. per lb. Machine cast iron, at 21c., is 1c. higher than last week.

Toronto, Ont., April 17.—The industrial situation continues favorable, although the continued increase in prices of raw materials and in some cases shortage of supplies is handicapping manufacturers. The possibility of higher prices on coal is also an important factor in the situation. The opening of navigation on the lakes will help to relieve the situation, but conditions at the mines are not any too favorable.

Steel

Developments in the steel market in the United States are being followed closely by Canadian interests, as the trend of events there will be reflected in this country. The fixing of prices between the steel makers and the American Government has not as yet affected the steel market at all, probably because of the comparatively small tonnage at present involved. There is still some possibility of the Allied Governments sharing in the U. S. Government's arrangements, in which event the aspect of the situation would be changed. Furthermore, the requirements of the American Government may ultimately develop into considerable tonnage, a contingency which would likely have an important effect on the situation. In the meantime prices are steadily advancing. A halt in the upward movement seems unlikely, as the mills are sold to capacity for several months ahead, and the demand for steel is on the increase. Owing to developments in the States, private consumers in Canada importing steel material may suffer from a further delay in deliveries and higher prices. For instance, prices of plates and black sheets have again advanced. Plates are now quoted at $7.50, and heads at $7.60 per 100 lbs. The demand for plates continues very heavy and some mills, it is reported, are refusing tonnage, being unable to accept any more business owing to the difficulty of making deliveries. Makers of cut nails have raised their prices to $5 per keg base. Wrought pipe has made another advance, the fourth in a very short period.

Prices of black sheets have advanced approximately 50c, No. 28 gauge being now quoted at $7.35, and No. 10 at $7 per 100 lbs. Premier 10¾ oz. are higher at $8.50, and No. 28 U. S. are $8.20 per 100 lbs. The demand for black sheets is heavy and the market very firm.

Prices of steel products in the United States continue to advance in spite of the recent fixing of prices to the Government. The agreed prices are $2.90 for plates and $2.50 for structural shapes and steel bars. Operating schedules have been arranged to give the Government material precedence over all other business. Although these figures represent a substantial concession, current prices have not been as yet affected; in fact, indications point to higher prices on steel rather than a revision to lower levels, as predicted in some quarters. Bessemer and open-hearth billets are now $75, forging billets $100, and open-hearth sheet bars $77.50, all f.o.b. Pittsburgh. The expectation of heavy Government requirements and congested condition at the mills on both Bessemer and open-hearth steel is largely responsible for the heavy advance in prices. Chicago warehouse prices of plates have advanced to 6c.

Pig Iron

The pig iron market continues strong, but it is difficult to name a firm price, as the situation is so uncertain. While $47 might be quoted on domestic foundry iron, this price is entirely nominal, and is liable to advance any day. The tight situation is largely due to the heavy demand for pig iron and sold-up condition of the furnaces, while stocks are also very low. Although $45 is being quoted at Buffalo for fairly good delivery, there is very little iron available, a situation which is reflected over here. The current prices on a few American pig irons are higher than last week, and are as follows:—Basic Valley furnace, $38; Bessemer, Pittsburgh, $42.95; Grey Forge, Pittsburgh, $37.95; No. 1 foundry, Buffalo, $45.

Scrap

Prices of copper and brass scrap are easier, although they are unchanged; in the meantime a decline appears to be probable. The weakness is due to the changed outlook for copper rather than to any material falling-off in demand. Prices of all steel scraps are firm, with a higher tendency. There is a good demand for steel scrap, and also for low phosphorus pig iron. The demand for steel borings and turnings is not heavy, as consumers seem to be well supplied.

Machine Tools

There is practically no change in the situation in the machine tool market. The demand for tools for munition plants is light, a few single tools representing the general run of business. There has been some inquiry for shipyard machinery during the week, and a few orders have been placed with local dealers. More business in this class of equipment is expected.

Supplies

There are indications of declining prices on high-speed steel. A new discount of list plus 90 per cent. has been made on high-speed drills up to ½ in., and double list plus 10 per cent. on high-speed drills up to 1½ in. Files have advanced, the new discount being 55 per cent. Prices of rubber belting are up; standard is now 40 per cent., and best grades 20 per cent. off list. An advance has been made in wood screws, the new discount on flat head bright being 72½ per cent., as against 75 per cent. formerly. Turpentine has advanced 2c to 75c per Imperial gallon.

Metals

There have been no important developments in the markets during the week, all metals are dull, due largely to the uncertain situation. This condition appears likely to continue until something more definite is known in regard to the requirements of the American Government. Copper is affected to a greater extent perhaps than other metals owing to the low price recently fixed on U. S. Government purchases.

Copper.—Little interest is being displayed in the copper market, and prices continue nominal and unchanged. There is, however, an easier undertone to the market, and there is a possibility of lower prices as a result of the recent sale to the U. S. Government at a considerably reduced figure. Local prices are unchanged in the meantime, lake and electrolytic being quoted at 40c and castings at 39c per pound.

Tin.—The market is firm and prices continue entirely nominal. The trade in the States is disturbed on account of the uncertainty caused by the restrictions placed upon shipments of tin from London and the East by the British Government, and the fear that limitations may be increased still further. Local quotations are firm and unchanged at 56c per pound.

Spelter.—Prices have declined locally in sympathy with an easier situation in the States. There appears to be some price shading by producers owing to falling off in demand and continued large production. Prices have declined 1c locally, and spelter is now quoted at 13c per pound.

Lead.—The sold-up condition of producers is holding the lead market firm, although business is not particularly active. Local price, 12¼c per pound.

Antimony.—The scarcity of spot metal continues, and prices are still nominal. Quotations firm and unchanged at 36c per pound.

Aluminum.—The market is quiet but firm, and quotations are unchanged at 68c per pound.

THE PASSING OF JIM BRADY

James Buchanan Brady, wealthy steel car manufacturer, well known to Broadway, New York City, and the business interests of the United States generally, died in the Hotel Shelburne, Atlantic City, N.Y., on April 13. Although his decease was anticipated, being at longest a matter of a few months, its immediate suddenness was wholly unexpected. In view of the varied nature of his career and his somewhat unique personality, our readers will doubtless find the following biographical sketch from the New York *Sun* of more than passing human interest.

Man of Business and Pleasure.

One book would be all about the James Buchanan Brady, of the daylight hours, voluntarily the hardest worked man in his offices at 170 Broadway, acknowledged "the best salesman in the country," a capitalist who at a pen stroke, had he cared to do it, could come close to shutting up an entire city of 25,000 souls in western Pennsylvania, inasmuch as almost the entire town is employed by his Standard Steel Car Company, and the company practically owns the town.

The biographer's other book would be even more spectacular, and it wouldn't have a line in it about James Buchanan Brady at all. Instead, it would have to do altogether with the Diamond Jim Brady who nightly came into being in the theatrical and restaurant region of Longacre Square when dusk fell—the Diamond Jim ablaze with the thousands upon thousands of dollars worth of jewels which gave him the sobriquet by which Broadway knew him; seated in restaurants before quantities of food so appalling that nearby diners, fascinated, let their own meals grow cold as they watched him demolish the dozens of raw clams or oysters and the piles of bread and catsup which he consumed while waiting for the soup and the birds or the double steaks and vegetables that always followed. He would finish a pound box of candy in five minutes.

A Great Patron of the Theatre

And much would have to be written about the Diamond Jim seated, now ablaze with still another set of jewels in an aisle chair in the front row on theatrical opening nights, while prima donnas or show girls nodded to him from the stage or, as sometimes happened, a privileged comedian on a first night boldly said, "Hello, Jim," over the footlights. And more than a chapter could be given to the monumental midnight supper after the performance, Diamond Jim, surrounded by troops of the loveliest ladies of the stage and, finally, one-stepping in a Broadway trottery until the roosters began to crow—easily the most popular man at the party.

So, from dusk until almost dawn, the Diamond Jim Brady would play with as much genuine relaxation as the James Buchanan Brady would labor with intensity in the financial district during daylight hours. And after a few, a very few hours of rest in his home at 7 West Eighty-sixth street, where his household consisted chiefly of Yamas, who was his faithful Japanese valet and guardian of the jewels, and his dog and the little cat he had picked up on the street in Baltimore and had made a pet of, Diamond Jim would become James Buchanan Brady again.

He never took an alcoholic drink in his life, never used tobacco in any form and he drank no tea or coffee. His constitution had a great deal of his own steel car construction in it, wherefore, despite the wracking nature of both his work and his play, he lived intensely night and day for many years before the final smash came.

He Had 200 Suits of Clothes.

Younger men who had tried the all-night parties of Broadway every night came and went, mostly went, the youngsters lasting only months or even weeks during the uninterrupted years that Diamond Jim was steadily adding glitter and picturesqueness to Broadway night life because of his 200 suits of clothes and his thirty sets of jewelry, each set consisting of fifteen pieces and five of the sets valued at $100,000 each.

The younger men who were mowed down quickly could recuperate somewhat, too, by sleeping all day, whereas Diamond Jim arose early and—now a quick thinking, soft spoken, alert James Buchanan Brady—was among the first on the job down town. But the youngsters who cracked under the strain usually dropped into bed drugged with alcohol and nicotine; Diamond Jim's excesses consisted solely of overdoses of the most excellent foods obtainable.

In the Brady biography there would have to be chapters in the Diamond Jim book also about his racing days, when he owned the crack $30,000 Oiseau and Gold Heels and other thoroughbreds. Back in those glad days his massive figure would wedge itself into the betting ring, sheaves of yellowbacks between his bejewelled fingers, and the bets he placed were of a size that made the bookies think hard.

Yells at Joy of Winning.

Once a Brady picking began to nose out of the ruck and light out for the finish with nothing in front of it but daylight even a blind man would know what was happening. For Diamond Jim, jumping to his feet in the grand stand, his heavily jowled face aglow with the ecstasy of the moment, would let loose bellowing yells of sheer joy that arose above the roars of the crowd and the blare of the band and the thunder of swift hoofs pounding past through the sunlit dust clouds. There are fans who believe that the echoes of those Brady yells still are haunting the deserted weed grown tracks.

When the Governor of the State brought an end to the Percy-Gray law and racing was ended, no darky stable boy or glum little jockey grieved more than Diamond Jim.

"Listen," he said solemnly to his office force in a little speech he made to his employees on the eve of a subsequent election day which was to decide whether or not the same Governor was to be returned to office. "I don't like to butt in on the politics of any man working here and I wouldn't discharge anybody for voting wrong to-morrow. But But!—if any one here casts a vote for this John J. Jungleface for Governor to-morrow and I find it out, then that member of this staff is going to lose my liking for him, that's all."

Gets New $250,000 Stomach.

So great was the publicity which attended Mr. Brady's so-called "new $250,000 stomach" in the summer of 1912—meaning thereby a recovery from kidney and stomach lesions following surgical and medical treatment at Johns Hopkins Hospital which enabled him to return to Broadway and momentous meals again after months of forced abstemiousness—the reading public, fed chiefly with happy yarns about the "new Brady stomach," almost lost sight of the scientific importance of his very fine gift to the Baltimore institution.

Upon his departure from Johns Hopkins, comparatively a well man again, Mr. Brady promptly handed over a sum in the neighborhood of a quarter of a million dollars to Johns Hopkins as an initial contribution for the building and maintenance of the James Buchanan Brady Urological Institute. Furthermore, he guaranteed at the same time an annuity of $15,000 to go toward the upkeep of the institute, and in a letter to Dr. Hugh H. Young, professor of urological surgery at Johns Hopkins, he said when forwarding his cash gift that he had just added a clause to his will providing for "a substantial sum" to be devoted to the future needs of the institute.

Pitied Other "Poor Devils."

Journalistic wags, who for years had been having much good natured fun at Mr. Brady's (rather at Diamond Jim Brady's) expense, may have written chiefly about the new "$250,000 stomach," but the medical and surgical world in general, and Baltimore in particular, appreciated the splendid gift at its real value. Here was a new unit in a great medical institution where not only "other poor devils can be made well again," as Mr. Brady put it, but which enabled Dr. Young and his assistants to do surgical and pathological research in urology upon a scale and with a scientific equipment which previously had been impossible.

There was a "Brady day" of civic importance in Baltimore when the institute was dedicated on May 4, 1915. Hand clapping finally was lost in cheers that day as the donor, blushing like a particularly adipose schoolboy, was thrust into the limelight to make a speech to the assembled civic dignitaries.

The Brady speech took up only a paragraph in the newspapers the next morning. At the end of the speech Mr. Brady would have become Diamond Jim again and hurried right back to his beloved Broadway had not Baltimore insisted upon a public reception, during which he was again forced into the spotlight.

He Gave Freely to the Poor.

Then there was a banquet in his honor in the evening, and when the coffee had been served some of the foremost men in public life in Maryland and great scientists and others of the mighty arose and told Mr. Brady that he was a big-hearted and altogether remarkable man—facts which wealthy associates and his proteges among the poor here had known for many years.

The aid he gave to the poor that came to him (and Diamond Jim's charities that became known were many), doubtless was given all the more heartily because for a long time he also had been very poor. He was born of Irish parents in Cedar street, on August 12, 1856. In the New York public schools he got the elements of learning, but he had to give up his books when a little chap and begin to earn his own living, first as an office boy with a downtown law firm. He was a messenger for a while also, and, in his youth, a baggageman at the old Grand Central station.

Then he got a job with the firm of Manning, Maxwell & Moore, machinery manufacturers, and early showed signs

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Goderich, Ont.—The Goderich Dry Dock & Shipbuilding Co. propose building a ship-repairing plant here.

Ottawa, Ont.—T. Lawson & Sons Machine shop on Wellington Street, was destroyed by fire recently. The damage is estimated at $8,000.

Vancouver, B.C. — The School Board contemplate making additions and improvements to the heating and ventilating plants in a number of schools here.

Vancouver, B.C.—The Great Northern and Northern Pacific Railways who are constructing a new union terminal here, will build machine shops, boiler house and water tanks in connection with the scheme.

Collingwood, Ont.—William Kennedy &Sons have applied for an additional 1,000 h.p. from the Hydro Commission for use with the electrical furnaces, which they are about to instal at their steel plant here.

Guelph, Ont.—The International Malleable Iron Co. are installing a new 20-ton milling furnace and three annealing ovens in the 216 ft. extension which they are building to their foundry. A new warehouse and shipping room will also be built.

London, Ont.—Plans have been prepared for the new foundry which Beatty Bros., of Fergus, propose building here.

Lethbridge, Alta.—Good progress is being made with the development of a coal mine at Taber. A four-mile spur is being constructed to the mine from the C. P. R.

Port Arthur, Ont.—The Ontario Hydro-Electric Commission will not proceed with the development of the Nipigon water power, as such a scheme is considered to be detrimental to the interests of the city.

Toronto, Ont.—Shipments of ore and concentrates from the property of the Kenyon Copper Mines, near Massey Station, have been resumed after several weeks spent in overhauling and enlarging the concentrating mill and flotation system. The stated capacity of the mill is now about 200 tons per day. The steam plant which has also been enlarged, is now about 300 horse-power capacity.

Hamilton, Ont.—The National Abrasive Co. of Boston and Amesbury, Mass., manufacturers of carbolon an abrasive material for grinding and polishing purposes, have decided to locate in Hamilton and have bought an acre and a half of land on Biggar ave. near Lottridge street. They will start erecting a factory immediately and expect to start operations in 90 days. The equipment and material is being ordered through the Ritchey Supply Co. of Toronto, who are the selling agents for this concern in Canada. Nathan C. Harrison is persident of the National Abrasive Co. and he has connected with him, J. T. Johnston, who is looking after the erecting and equipping of the Hamilton factory.

GENERAL

Montreal, Que.—The Montreal Box Board Co. will build an addition to its factory, to cost $20,000.

Belleville, Ont.—R. J. Graham's evaporating plant was destroyed by fire on April 11. The tin shop, cold storage building and the chemical warehouse on Front Street were also burned. The total

---

of salesmanship ability that amounted almost to genius. He saved his money, and after he had been with the firm a few years he put up his savings to back a metal cutting saw and thus got his first real start toward riches. Then he became identified with the Fox Pressed Steel Company, subsequently the Pressed Steel Car Company, and finally with the Standard Steel Car Company, of which he was vice-president from the time it was organized until his death.

Started on "Beef and Beans."

"I began to eat away down town, where corned beef and beans cost a dime a plate," he told the New York Society of Restaurateurs when called upon for a speech at the restaurant men's annual dinner in 1916. "Then I got swell enough to go to my old friends, Smith & McNeill, where I could get one of the best meals of the day for 25 cents. And by degrees I edged my way up town until I was eating table d'hote dinners for 30 and even 40 cents. Finally I arrived right among you gentlemen. Since then I've eaten everything in sight except the tablecloths."

The one-time baggage smasher at the Grand Central Station was host at a dinner here which he gave at the end of the summer of 1912 to celebrate his recovery at Johns Hopkins. One of his guests was, at the time of the dinner, of some importance around that same Grand Central Station, the guest in question being Charles S. Mallen, president of the New York, New Haven and Hartford. Some time later, while testimony was being given before the Interstate Commerce Commission, it was learned that one of Mr. Brady's companies had sold the New Haven road—even the New Haven — more than $8,000,000 worth of steel cars. One might reason from this that there was more careful thought and deliberation in selecting the guests at a James Buchanan Brady dinner than at the happy-go-lucky dinner and supper parties given by Diamond Jim Brady.

Wonderful in Salesmanship.

His faculty for salesmanship was uncanny. Largely he got results because he was so close a student of detail as well as of men. He knew railroading well and he knew all about steel cars. If he thought a road needed something in his line he would take a trip over that line and soak in its needs by means of remarkable observation. Then he would call to see the president of that road and tell him that the line needed cars. If the official wouldn't agree with him out would come the Brady statistics and other data—exact figures to prove that the rolling stock was below standard. Usually he got the order.

Upon his death last week estimates were made of his fortune that ranged all the way from $5,000,000 to $10,000,000. His jewels, which he began to collect about twenty-five years ago, have been valued at $1,200,000, most of which it was reported, will go to the Metropolitan Museum of Art. He had one diamond said to be worth $50,000; sets of pearl, ruby, diamond, cat's eye and emerald, each valued at $100,000; great shirt studs and rings crusted with perfect gems and literally as large in circumference as a fifty-cent piece—some even larger; rings, the jewels of which arose almost an inch above his knuckles in pyramids of glitter, the gold or platinum mountings that held the gleaming pyramid covering not only the finger upon which the ring was worn, but more than half of each of the fingers immediately adjoining as well; diamonds and rubies and pearls hidden beneath his clothing in the form of ornaments for suspender or garter buckles; a set of waistcoat buttons alone which more than represented the interest on $1,000,000 at 4 per cent. —that was the way Diamond Jim Brady went in for jewelry.

Loved Gems as Works of Art.

And, oddly enough, he didn't wear his enormous jewels to impress others. Gems were a passion with him. He loved to wear them, to handle them and look at them even in the privacy of his own home—just as another type of man would find his greatest joy alone among his Corots, his Millets or his latest Velasquez. But the intellectually imaginative charm of a silvery Corot had no part in Diamond Jim's joys. His pleasures were sensuous and of the earth earthly—resplendent jewels, the loveliest among Broadway's stage beauties, who surrounded his restaurant tables in bevies; the richest of foods and the gayest of musical comedies.

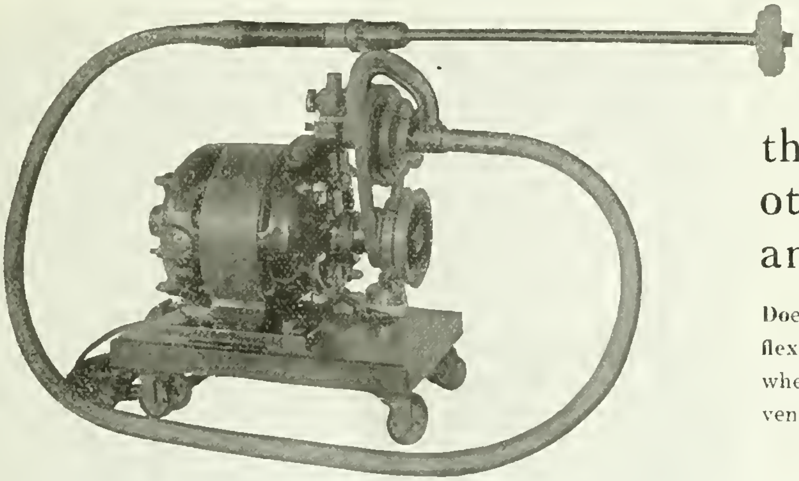
If his voice was loudest at the racetrack when his horse was winning in the old days, he was the quietest at his parties. In the popular mind Diamond Jim Brady suggested bluster and noise and brag. Really he was quiet, almost solemn, in movement and speech. There was in fact a certain gentleness in the way he addressed one which those who talked with him found very winning and not at all what one would expect from a man of his massive form and heavy features.

Besides his vice-presidency of the Standard Steel Car Company he was a director of the Standard, president and director of the Independent Pneumatic Tool Company, vice-president and director of Manning, Maxwell & Moore, Inc.; president and director of the Thermoton Company, director of the United Injector Company, vice-president of the Keith Car and Manufacturing Company and of the Osgood Bradley Car Company, director of the Consolidated Safety Valve Company, and he was interested in several other enterprises connected with railroad products.

Aikenhead's M-6 Shell Machine

for cleaning out insides of 4.5 inch Howitzer and 6-inch shells and for retouching rough spots

This machine has been used with immediate success in a number of large shell factories in Canada. A 14½" special spindle is supplied for 4.5 shell work and a 20" spindle is used on 6" shell work. Specially adapted for cleaning the base of shells *inside*.



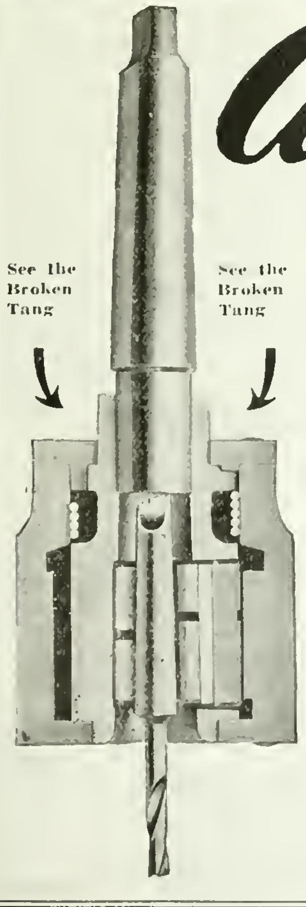
The Strand flexible shaft has a *metal casing* that will outwear any other now on the market and adds life to the shaft.

Does away with the trouble common to other flexible shafts. Freely flexible to a certain radius, where it automatically forms a stop, thus preventing accidental short bends.

For full particulars write.

Aikenhead Hardware Limited

17, 19, 21 TEMPERANCE STREET, TORONTO



Aikenhead's New Chuck

Don't Throw Away Broken Tang Drills

Perhaps you are about to discard some taper shank drills because the tangs are broken off—DON'T DO IT—they are worth their weight in gold. You can use them just as they are with a

Wahlstrom Automatic Chuck

One chuck holds drills from 1/16" to 1¼"

and you won't have to take time from your production to repair them.

Tool changes are made in two seconds—just grasp the shell of the chuck with one hand and put in or remove the tool with the other—no collets—no lost time, for the spindle never stops. The jaws grip NOT BY THE TANG, BUT ON THE SIDE OF THE TAPER—there's no chance for slippage—a Wahlstrom won't even mar the shanks.

Aikenhead Hardware Limited

17, 19, 21 Temperance Street - Toronto, Canada

loss, including building, plant and vegetables, is estimated at $300,000. The buildings burned were insured for $18,500, the machinery for $89,500, and there was $100,000 insurance on a large quantity of canned goods.

ELECTRICAL

Hamilton, Ont.—The Wentworth County Council will secure an estimate from the City Council on the cost of lighting several country roads for a distance of half a mile from the city.

Hamilton, Ont.—The Hydro Department will be asked for estimates for lighting for the various highway approaches to the city for a distance of half a mile from the limits.

Yarmouth, Ont.—A resolution has been passed authorizing the Hydro-Electric Commission to prepare an estimate of the cost of installing an electric service in the Township of Yarmouth, between the City of St. Thomas and the Village of Belmont.

Toronto, Ont.—The Hydro-Electric Commission contemplate a further development of 1,500 h.p. at Eugenia Falls and 2,000 h.p. at Big Chute. The proposed expenditure for Eugenia Falls extension is placed at $217,897, and that for the Severn River extension $121,238.

MUNICIPAL

St. Mary's, Ont.—The Town Council contemplate an expenditure of $6,000 on improvements to the civic power plant.

Listowel, Ont.—The by-law was carried to grant a loan of $15,000 to assist the Perfect Knit Mills, Ltd., to erect a spinning mill.

Saanich, B.C.—The City Council are considering the question of purchasing a motor chemical engine for the fire department.

Amherstburg, Ont.—The Town Council has accepted an offer from the Brunner-Mond Co. of Canada to build for Amherstburg a new waterworks plant.

Tillsonburg, Ont.—Two more industrial propositions have been presented to the Town Council, and both favorably received. A resolution was passed by the businessmen present recommending the council to give them favorable consideration.

Sudbury, Ont.—A by-law will be submitted to the ratepayers on April 30 to authorize an expenditure of $46,000 for a stand pipe and auxiliary main, and $2,500 for alterations to lake sewer pumping station. W. J. Ross, town clerk.

Montreal, Que.—Only six tenders were received by the Board of Control for the supply of street cleaning equipment. The firms who submitted bids are the Comet Motor Co., A. Jennings & Co., Peerless Motor Sales, General Supply Co., of Canada, Victor Levesque, and the Tiffen Truck Co.

Smiths Fall, Ont.—G. A. Burgess, of Carlton Place, Ont., has submitted a proposition to the Town Council to supply cheap power, providing he is given permission to erect transmission lines in the town. Mr. Burgess estimates that he has for sale over 4,000 h.p., at present undeveloped at Rose Bank and High Falls.

TENDERS

Yorkton, Sask.—Tenders will be received until April 30 for one 350-400 b.h.p., combined Diesel electric unit. Specifications may be obtained from F. J. Pilkington, town clerk.

Adamsville, Que.—Tenders will be received up to May 1 for construction of a steel bridge, one span 125 feet, and abutments for same. Plans and specifications can be obtained from O. Landry, Sec.-Treasurer, Adamsville.

Montreal South, Que.—Tenders will be called some time in April for a 30-h.p. motor-driven turbine pump and a 150-h.p. gasoline engine-driven turbine pump for fire purposes, etc. E. Drinkwater, St. Lambert, Que., is the engineer.

Edmonton, Alta.—Tenders will be received up to May 1 for the supply of automobile markers for the Province of Alberta, during the year 1918. Specifications may be obtained on application to the Deputy Provincial Secretary, Edmonton, Alta.

Sherbrooke, Que.—Tenders are being called for 30 miles of copper wire, six transformers and other material for a transmission line to Two Mills Falls power plant. Full information may be obtained from J. R. McGregor, electrical superintendent, Sherbrooke.

Hamilton, Ont.—Tenders will be received up to Wednesday, April 18, for supplying the City Corporation with 400 feet of ¾-inch chemical fire engine hose and with 1,000 feet of 2½-inch cotton rubber-lined fire engine hose, according to specifications prepared by the Chief of the Fire Department, copies of which may be had on application at his office.

Winnipeg, Man.—Tenders addressed to the Commissioners of the Greater Winnipeg Water District will be received up to April 16, for the supply of miscellaneous bronze castings, brass piping, etc., which enter into the construction of a Venturi meter. Specifications and form of tender may be obtained at the offices of the district, 501 Tribune Building, Winnipeg.

Winnipeg, Man.—Tenders addressed to R .D. Waugh, chairman of the Commissioners, Greater Winnipeg Water District, up to April 16, for the supply of approximately 12,000 feet of 48-inch and 1,300 feet of 60-inch cast iron pipes, together with numerous specials and gate valves. Specifications may be obtained upon application to the offices of the District, 501 Tribune Bldg., Winnipeg.

Winnipeg, Man.—Tenders, addressed to the chairman, Greater Winnipeg Water District Commission, at 501 Tribune Building, Winnipeg, will be received up to April 16, for the supply of one second-hand passenger coach, also one second-hand caboose, both standard gauge. Tenderers to supply own speci-

Kindly mention this paper when writing the advertiser.

fications. Further particular on application to undersigned, R. D. Waugh, chairman of Commissioners.

Drummondville, Que.—Tenders will be received until April 20 for drilling wells and supplying pumping equipment.

Winnipeg, Man.—Tenders, addressed to the Chairman, Board of Control, will be received up to April 16, for the supply of labor and materials required in the erection of a 150-foot brick or concrete chimney for the Elmwood Incinerator. Plans, specification and form of tender may be obtained at the office of the City Engineer, 223 James Avenue.

Ottawa, Ont.—Tenders will be received until April 21 for steam boilers and stokers required for the Central Heating Plant for the Parliament Buildings. All tenders to be based on the supplying and erecting of three water tube boilers, each having a rated capacity of 500 horse-power, together with fittings and soot blowers. Each tender shall give separate quotations for supplying and erecting, in connection with boilers, three automatic stokers. One boiler and stoker shall be erected complete within five months after date of awarding contract and the other two shall be erected before January 1st, 1918. Plans, specifications and any other information required can be obtained at the office of the general contractor, P. Lyall & Sons Construction Co., Ltd., Ottawa.

PERSONAL

Lieut.-Col. Wood Leonard, D.S.O., of London, Ont., was killed in action recently in France, while in command of the 3rd Artillery Brigade. Col. Leonard was a son of Frank E. Leonard, and was associated with his father and brothers in the firm of Leonard & Sons, the well known engineers of London, Ont. He was a graduate of the Royal Military College, Kingston, Ont., and went overseas in 1914 in command of the 6th Field Battery. Col. Leonard was 34 years of age.

Prof. John C. McLennan has been appointed to the British Board of Inventions and Research, under the chairmanship of Sir John Fisher. Prof. McLennan is head of the Department of Physics of the University of Toronto, having been connected with the institution since 1892. He will probably occupy the post for the summer, and will leave shortly.

Henry A. Everett, at one time a prominent street railway magnate of Cleveland, O., died at Pasadena, Cal., on April 11, aged 60. He was formerly president of the Cleveland Railway Co., the Toledo Railways and Light Co., and London Street Railway Co., London, Ont., electrical engineer of the Montreal Street Railway, and was financially interested in many electric traction companies in Canada and United States.

Sir Lyman Melvin Jones, president of the Massey-Harris Co., died in Toronto last Monday after an illness of two months' duration. The late Sir Lyman was a native of York County, and was born in 1843. His first real employment was as a young man with the firm of A. Harris, Son & Co., Brantford, Ont., and while still in his twenties was admitted as a partner. In 1879 he was sent to Winnipeg as Western manager, and later was made general manager. The formation of the Massey-Harris Co. in 1891 brought him to Toronto as general manager of the consolidation. He became president as well in 1902, and held that post until his death. He was also president of the Bain Wagon Co., Woodstock, Ont., and the Johnston Harvester Co., Batavia, N.Y. The deceased was called to the Senate in 1901, and ten years later knighted by King George.

TRADE GOSSIP

The Coleman Fare Box Co. has removed its plant from Tottenham, Ont., where the business was founded, to 1191 Bathurst Street, Toronto.

Will Develop Peat Lands.—The Prince Edward Island Provincial Legislature has under consideration a bill to develop plant lands. Tests will be made to determine its suitability for fuel.

The Phoenix Bridge & Iron Works, Montreal, have been awarded the contract for the steel bridge across St. Francis River for the municipalities of East Angus and Westbury, Que. Contract price $45,000.

Galt, Ont.—The Canadian Brass Mfg. Co., has acquired the B.O.T. Mfg. Co. of Toronto, established in 1910. The head office will be at Galt and the Toronto office becomes a branch. G. A. Dobbie, of Galt, is president.

The Multisize Rotary Press Co., 19 Charlotte Street, Toronto, A. C. Ransom, president, are installing a machine shop at the above address to take care of machine work in connection with printing presses which they are now building.

Railway Board Suspends Tariff.—The Dominion Railway Commisssion has suspended the operation of the new lake and rail tariff of the railways between points East and West. There have been many protests against the increase of the rates as "unjustifiable," and because of the lack of notice; and the case will be argued on the merits, the old rates applying meanwhile. The companies have based their claims largely on the scarcity of tonnage, due to the transfer of lake boats to ocean services.

Welland Industries Grow.—The annual report of L. B. Duff, Industrial Commissioner of Welland, Ont., for 1916, shows an industrial growth in Welland of almost incredible proportions. The value of manufactured products was $19,375,115, an increase of more than six millions over 1915, and thirteen millions over 1912. The advance is not confined to munitions, the value of munitions output not exceeding five and a half millions of the total. The pay roll totalled $3,610,336. The increase in the rate of pay is shown by the fact that the number of industrial workers was 4,890, as compared with 3,000 in 1912. A million and a half was spent on enlargement of plants.

Equipment, Methods and Devices for Producing 9.2 in. Shell

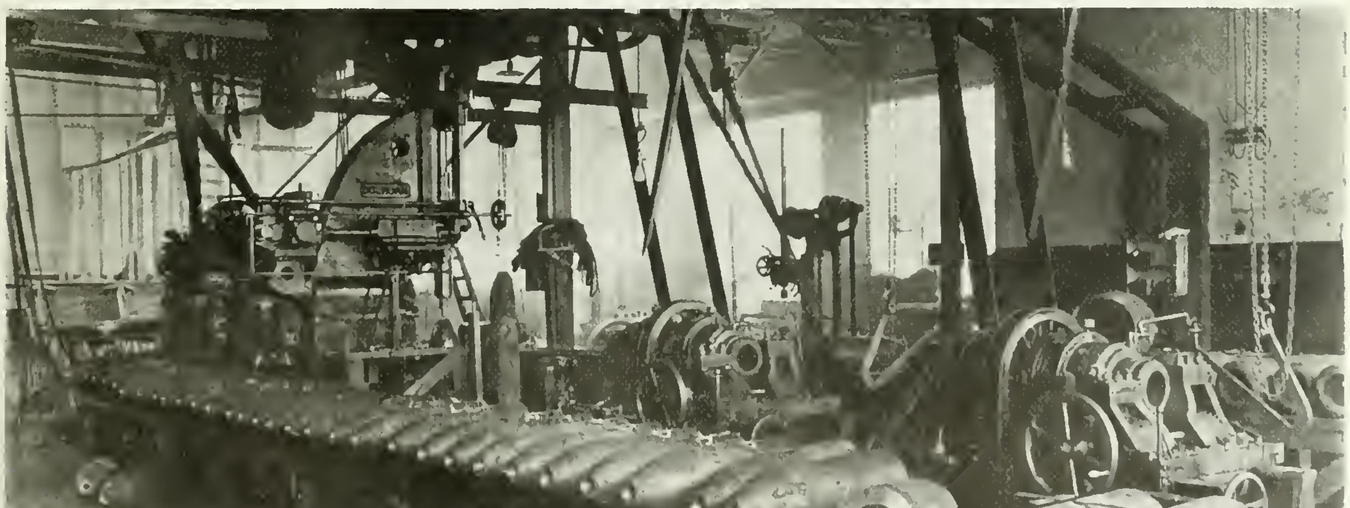
Staff Article

The plant here featured was organized solely for the purpose of machining 9.2 in. high explosive shell, and from a study of the nature and layout of the machine tool and other equipment as described and illustrated, it will become evident that production achievement was not only possible but certain of realization. As in numerous other instances, however, the personal element has contributed very materially to the degree of success attained.

THE manufacture of 9.2-in. high explosive howitzer shells is of special interest, in that it is the largest calibre shell being made in Canada, and also by reason of the heavy equipment required for its production. Another feature common as well to 8-in. shell, but not necessary for 4.5 in. or smaller shell is the system of hoists and runways required to facilitate handling. The forging for a 9.2 in. shell weighs approximately 387 pounds, and thus special provision has to be made for moving it from one operation to another. The illustrations accompanying this article show this feature in its various aspects. At this plant the floor of approximately 40,000 sq. ft. was of sufficient size to permit of all the machinery, with the exception of that in the tool room, being placed in one shop, the equipment being installed so that the shells move forward all the time, for the most part on benches or runways, thus accelerating production and reducing handling to a minimum.

General Layout of Plant

The general layout of the plant may be described as follows:—The forgings are brought in on a spur from a steam railway and deposited in piles outside the main shop and under cover. When required they are picked up by a chain hoist and brought into the main shop for the first operation, that of marking and centering the nose. Another hoist carries the forgings to a battery of drills to have the hole in the nose drilled and the nose faced up. They are then rolled along a bench to the cutting-off machines. After the open base end has been cut to an approximate length, the forgings are carried by means of a hoist to a runway extending practically three-quarters the length of the shop, and

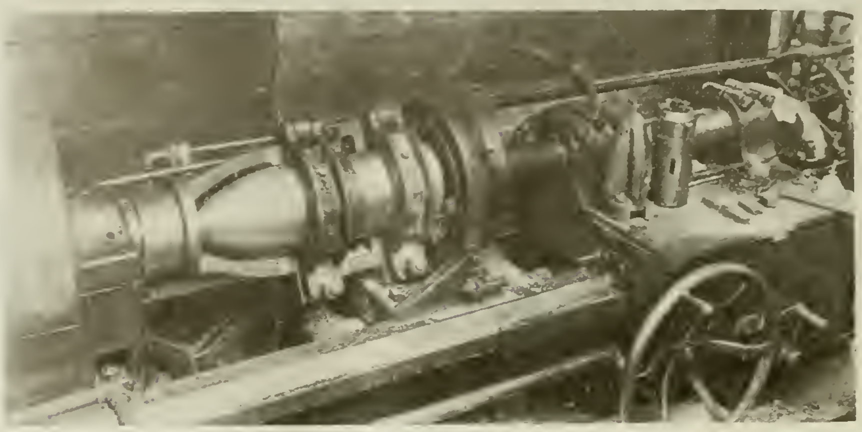


INITIAL OPERATIONS OF DRILLING AND FACING NOSE AND CUTTING-OFF OPEN BASE END. FORGINGS ON RUNWAY IN FOREGROUND ARE READY FOR ROUGH TURNING serving half its width. Two long runways built up with cast iron legs and 6-in. I-beams, serve four rows of lathes, two on either side, with a "Wright" hand-operated chain block or hoist to each machine for lifting the shell from the runway to lathe and vice versa. On the completion of each operation the shell is rolled forward on the runway to the next lathe and so on. The operations performed in this section are in the following sequence, and take in all four rows of lathes:—Rough turning outside; boring inside; boring nose for thread; finish turning outside; counterboring and recessing base; wave and undercut band recess; milling thread in base end; milling thread in nose end. An interesting feature in this section of the plant is the installation of 33 "Bridgeford" lathes, including twelve for rough turning, fifteen for boring, and six axle lathes for finish turning operations.

After the preliminary inspection at the end of the shop, the shells are washed to remove the grease and then rolled along a bench to have the adapters fitted. For the subsequent operations the shells move forward along the other side of the shop, being rolled along benches from one stage to another, until they arrive at the end from which they started, ready for boxing. The section of plant devoted to the manufacture of the adapters is at the farthest end from the starting point and adjoins the department where the adapters are screwed into the base. Incidentally it might be stated that the adapter is a solid steel forging which is screwed into the base of the shell. The shell has to be left open at the base to allow for machining inside. The adapter also serves another purpose of ensuring that the base is free from flaws or "pipes," thus preventing a premature explosion when the shell is being fired from the gun. A similar precaution is taken in all high explosive shells. For all machining operations in this section of and also throughout the plant "Wright" hoists are used for handling the shells any time they have to be lifted to or from the benches. The illustrations show the system employed in handling the shells.

Principal Features of 9.2-in. Shell

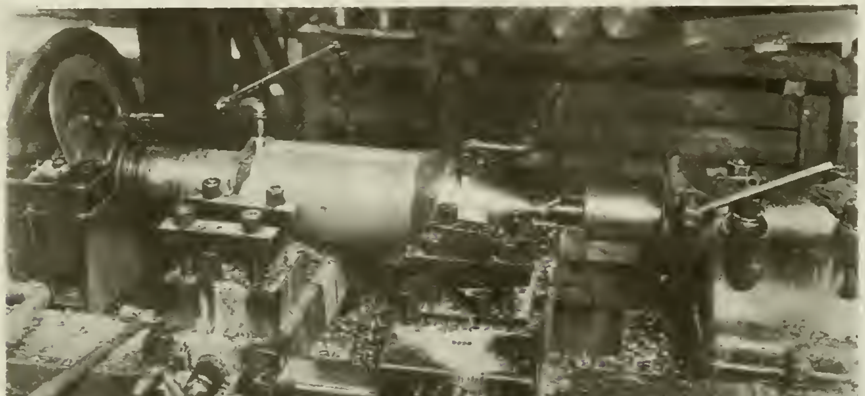
Before proceeding with a description of the manufacture of 9.2-in. shell a few particulars regarding the size and weight may be of interest. The forging has an open base end and a conical nose, and, as already stated, weighs approximately 387 pounds. It has to be not less than 28⅜ in. long over all, and is 10 in. outside diameter. The billet from which the forging is made weighs approximately 389 lbs., and is about 17¾ in. long by 9 15/16 in. in diameter. The finished shell weighs 252 lbs. 11 oz. empty, and 290 lbs. filled; the charge of explosive, T.N.T., weighing 34 lbs. The overall length without fuse is 26.83 in., the outside diameter is 9.155 in., and inside diameter 6.50 in. The adapter forging weighs about 47 lbs. All machining operations have to be very accurate, as the difference between high and low limits is very fine. In the weight of the shell plus or minus 3 lbs., 12 oz toleration is allowed.



BORING ON "BRIDGEFORD" LATHE WITH "DAVIS" CUTTER HEADS ON BORING BAR.

Centering Nose

The first thing to be done before machining operations on the shell can be attempted is to centre the nose. The forging is first of all placed on an inclined post, the nose chalked, and four marks made with a scribing block. A small hole is punched between the markings, and the forging is then taken over on a hand truck to a vertical "Barnes" drill, where the nose is drilled and countersunk. For this operation the forging is slipped over a post pivoted at the bottom. When the forging is on the post it is swung over into vertical position for centering.



ROUGH TURNING OPERATION ON "BRIDGEFORD" LATHE.

Drilling and Facing Nose.

One "Colburn" and three "Baker" drills are installed for drilling and facing the nose. The fixture for holding the forging consists of a vertical post, with a conical head, under which is a spring. The post rests on a sliding base, which is pulled away from the drilling machine for the forging to be placed over it. The forging is lifted on to the post by a chain hoist and is then placed in position for machining. The hole is drilled first; then the drill is replaced by an end mill, which faces up the nose.

Cutting Off Base End

The forgings are removed from the drills, placed on a bench or runway, and rolled along towards the cutting-off machines for the base end to be cut off. The forging is first marked for cutting off, the distance being gauged from the face of nose. The jig used for marking off has a small punch attached to the end near the base. The operator punches a number of small holes to mark the position for cutting off. There are three cutting-off machines, supplied by the Williams Tool Co., Erie, Pa., a hoist for each being provided for lifting the shells to and from the runway. The cutting-off machines are all the same type, and are arranged in a row parallel to the runway. Each machine has two tool posts, front and back, the cutting-off tools working simultaneously.

Rough Turning Outside Body

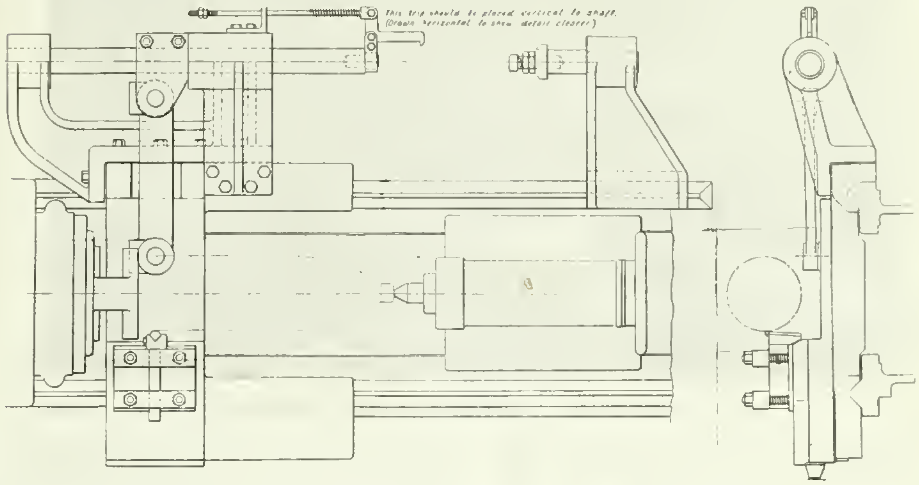
The next operation consists of rough turning the outside of body and profile on a battery of twelve heavy duty "Bridgeford" lathes. These latter are 27 in. by 12 ft. machines, and have variable speeds and feeds. Each lathe is driven by a Positive Clutch & Pulley Co. friction clutch. They have a double carriage with independent control. Each lathe is equipped with a special roller chuck for holding the open base end.

There are three rollers in the chuck which automatically expand inside the shell base and hold it firm. For holding the nose end, a split expanding-bushing is used, into which is driven the centre. There are two tool posts—one tool forming the profile and the other roughing the body.

The profiling attachment consists of a slotted bar carried on brackets at the back of the lathe. Fastened in the slot is a pivot, which is connected to the cross slide by means of a radius bar. As the carriage moves forward, this bar regulates the travel of the cross slide, and also, of course, the tool post which is mounted on the cross slide. The other tool begins cutting at the shoulder of shell and travels in the same direction towards the headstock, only parallel to the shell. One roughing cut only for each tool is necessary at this operation. Production at this operation has been as high as 38 shells in ten hours. There are four rows of lathes for this operation, and "Wright" hoists are used for handling the shells.

Inside Boring

After being rough turned the shells are rolled along the runway to the next set of lathes for the inside boring operation. Fifteen "Bridgeford" boring lathes take care of this, and are installed in four rows alongside the runways with hoists for handling the shells. The lathes are of same size and general design as those already mentioned, but are equipped with a boring bar taking "Davis" boring heads. A special cradle chuck is used for holding the shell, the latter being dropped into the chuck and secured with two clamps. One end of chuck is carried on the lathe spindle, and the base end revolves in a steady run. The "Davis" boringheads are interchangeable with male taper on the boring bar.



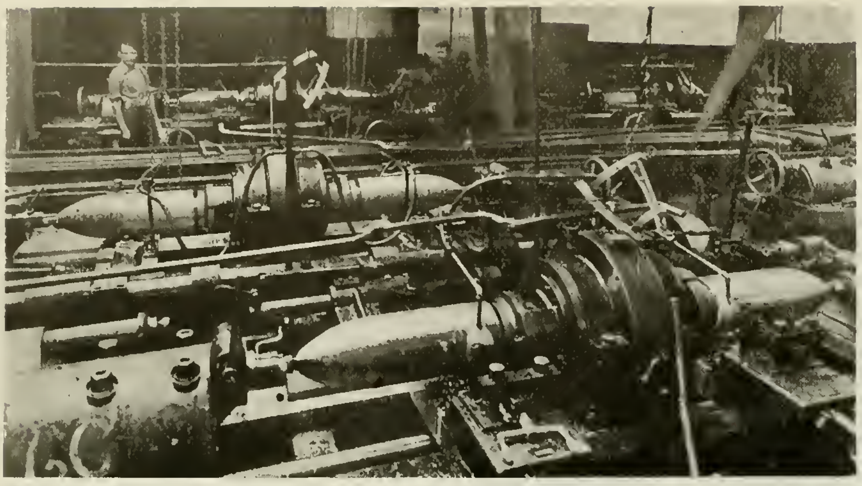
PROFILING ATTACHMENT AS FITTED TO "BRIDGEFORD" AXLE LATHES FOR FINISH TURNING OPERATION

Three boring tools are used. The first is a four-point body roughing tool, the second a four-point profile roughing tool, while the third finishes the body and profile. The lubricant enters the shell through the spindle to wash the chips out. On this operation 43 shells have been bored out in ten hours.

Boring Nose for Thread

Next in line are three Davenport 24 in. x 10 ft. engine lathes for machining the nose preparatory to threading. The nose is not threaded at this operation, being done later on a thread miller. An expanding arbor is used for holding the shell, as the nose must be in line with the bore. The arbor is secured to the lathe spindle, and is also supported at its base by a steady rest. At the front end of the arbor are three projections or studs which centre the shell and, at the same time, expand inside it, holding the shell firm. The base of shell rests on a taper bearing at the base of arbor, which also aids in keeping the shell concentric. The lathes are equipped with a "Phoenix" turret attachment, having four tools. The first is a "Davis" boring tool with two cutters which bore out the hole in nose right through. The second tool bores the hole for the threads as far as the retainer seat, while in the third turret face is a bar with a recessing tool. This tool forms the recess for the threads to finish in. and is 1.2 inches from the nose. The fourth tool is a

GENERAL VIEW OF "BRIDGEFORD" LATHES ON ROUGH TURNING AND BORING OPERATIONS, ALSO ARRANGEMENT OF RUNWAYS AND WRIGHT HOISTS FOR EACH LATHE



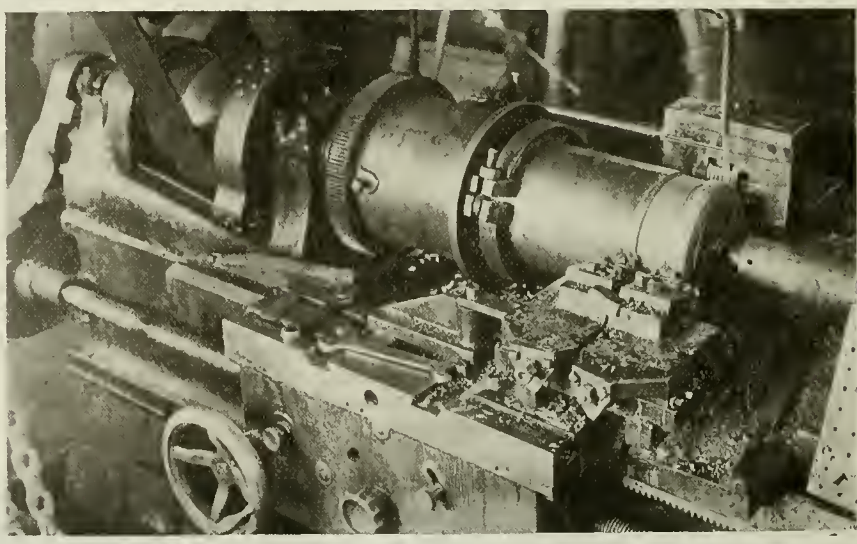
FINISH TURNING OUTSIDE BODY AND PROFILE ON "BRIDGEFORD" AXLE LATHE.

nose reamer which chamfers the nose and forms a bevel for fuse seat. The nose is now ready for threading.

Outside Finish Turning

At this operation the shell body is finish turned outside, including the profile. "Bridgeford" axle lathes are used for the work, there being altogether six of them installed on either side of the runways and in line with the lathes referred to in the preceding operations. They have a centre drive with a chuck on either side of the drive head, the expanding roller chucks being of same type as were used for rough turning. Two shells can thus be turned on one lathe. When chucking the shell for this operation, a fixture is used to ensure the profile being true. In the early days it was found that if the base of shell came up against the chuck face it had a tendency, in some cases, to throw the profile out, as the base at this stage of manufacture is not always square with the side. To obviate any trouble in this regard, a length gauge is put inside the shell right up to the nose, the other end of gauge resting on the chuck face when the shell is being turned. The face of shell base is thus free. A split bushing and centre is driven in the nose as is done at the rough turning operation. There is only one tool post on each side of lathe, a specially designed profiling attachment enables one tool to turn both the profile and the parallel part of shell. The turning tool has a semi-circular cutting edge which has been found to be the most suitable shape for profiling.

The profiling attachment is carried in brackets at the rear of the lathe, each side having a separate profiler. The brackets carry a 2 15/16 in. shaft with a clamp attached acting as a pivot for the radius bar which connects with the cross slide carrying the tool post. The tool starts cutting at the base end of shell and travels forward parallel to the shell up to the shoulder. During this time the carriage and profile attachment travel along together until the bar at the back comes up to a stop. When this bar hits the stop, profiling begins. The clamp being fixed to the bar remains stationary against the stop and therefore draws the tool post by means of the radius bar, thus forming the profile. This profiling attachment was designed at the plant and is shown in the line drawing. It is a comparatively simple device, but it has proved very satisfactory. Before the shell is removed from the lathe, the carriage is moved back to the base end, and that part of the shell body behind where the copper band will be, is finish turned to a shade smaller diameter than the rest of the body. The corner at base is also turned off, forming a bevel. The shell is then lifted out of the lathe by a chain hoist and rolled along the runway for the next operation.



WAVING AND UNDERCUTTING—GRAY MFG. & MACHINE CO. ATTACHMENT.

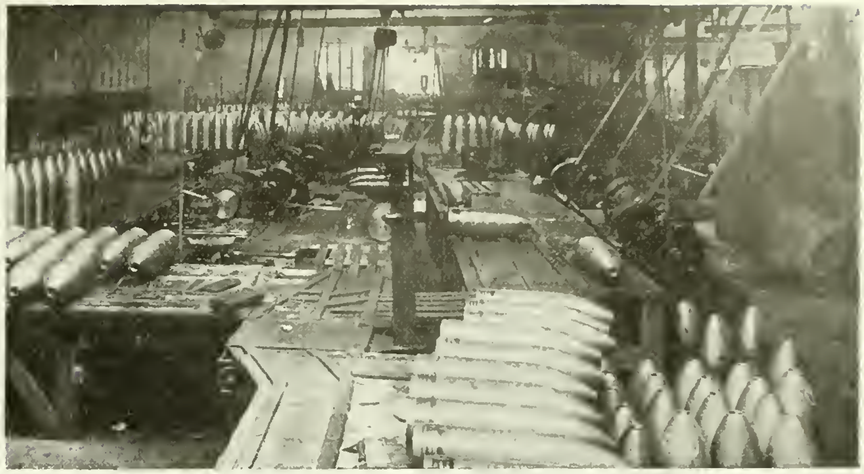
Counter Boring and Recessing Base, Rough Turning Copper Band Groove

This series of operations follows, the first of them being done in "Le Blond" lathes equipped with a turret attachment. The shell is held in a box chuck, while a steady rest supports the base end. The first tool in the turret faces up the base end; then follows the second tool which rough counterbores inside the base, while the third tool finishes the counter bore. The fourth forms the bevel on base on the outside edge. There are two diameters in the counter bore. the first, nearest the outside, is .62 ins. deep and 7 ins. in diameter, and takes

SCREWING ADAPTER IN SHELL BASE, SHOWING ALSO, IN FOREGROUND, FINISHED ADAPTER AND OPEN END OF SHELL READY TO RECEIVE IT.

the flange of the adapter. The second, for the threads, is 2.3 ins. deep and 6.49 ins. in diameter before threading. The finished length for facing up the base end is corrected by a bar gauge.

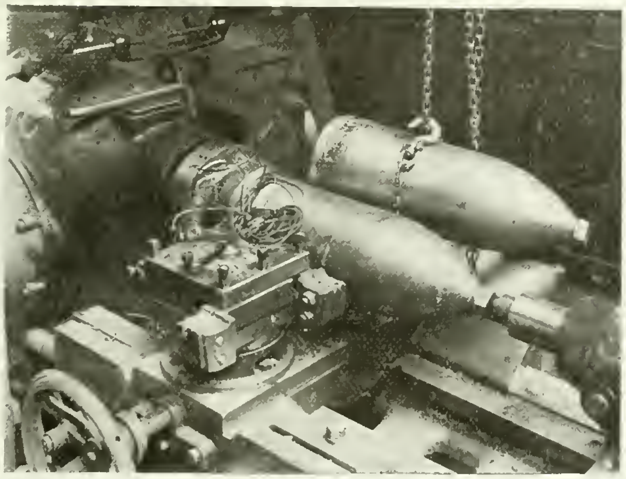
Rough turning or hogging the copper band groove is really a minor operation and is done to relieve the tools when waving and undercutting. Three "Le Blond" engine lathes are used with an ordinary side tool post. The shell is held in the lathe by a split bushing centre at the nose end while a circular centre plate is driven into the base end. A roughing cut is taken to remove superfluous metal before waving.



RECTIFYING DEPARTMENT, SHOWING ARRANGEMENT OF BENCHES, LOCATION OF SCALES, BASE FACING LATHES, ETC.

Waving and Undercutting

In the 9.2 ins. shell there are 7 waved ribs, and the groove is approximately 2.7 ins. wide. Three engine lathes are employed all equipped with a waving attachment made by the Gray Mfg. & Machine Co., Toronto. The nose of the shell is held in a pot chuck with a driving clamp, while a circular plate centre is fitted in the base end. It will be noticed from the illustration that the undercutting tools are at the front and the waving fixture is at the back. The waving motion is obtained by means of a cam inside the fixture, driven by compounded gears from the large gear on the main spindle. The feeding is done by a bar cam in the fixture. The diagonal feed for the undercutting tools is obtained by using a cam bar, the end of which will be seen outside the fixture, to the left. The waving and undercutting is done simultaneously.



TURNING COPPER BANDS ON CONRADSON LATHE.

Milling Thread in Base and Nose

The threads in both the base and nose are milled. The machines used for both operations are "Holden-Morgan" thread millers. There are five of these machines installed for milling the base threads and two for nose threads. The machines for both operations are essentially the same, and are standard for this class of work. The shell is held in the driving head and makes one revolution while the cutting hob which has an independent drive mills the complete threads. The hob for milling the nose threads is of course smaller, otherwise the method of operation is the same. The shells are handled with chain hoists as in the other operations. In the base there are 8 threads to the inch, left hand, and in the nose 14 threads to the inch, right hand.

ELECTRIC BAND HEATERS AND COPPER BAND PRESS.

Preliminary Inspection

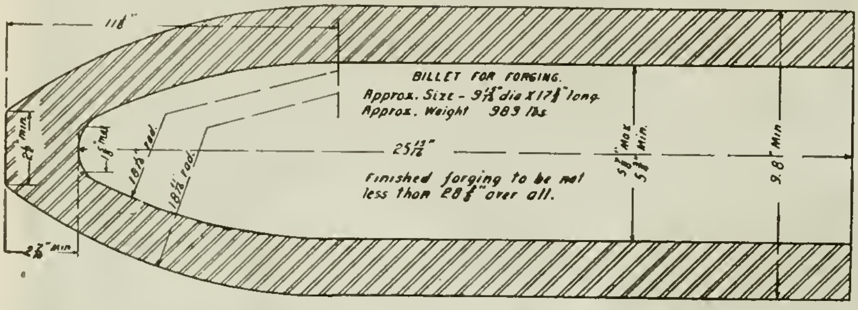
What might be called the first series of operations have now been completed, and the shells undergo a preliminary shop inspection, which is followed by a series of more or less minor operations. The shells while laid on a bench have compressed air blown in to remove chips, and any shell found at the inspection to be rough in the bore is carried over to the buffing machine to be rectified. These buffing machines are of simple design and consist of a wooden stand carrying a cradle on wheels supporting the shell, and also the buffing attachment. The buffer consists of a round bar having two short arms each holding at the end a piece of old emery wheel. The bar is placed inside the shell and the machine started. The centrifugal action of the revolving bar throws the arms out against the inside of the shell and grinds away the rough spots. Any shells rough on the outside are filed smooth while revolving on a fixture with rollers at the side of the bench.

The shells are washed in tanks containing hot liquid to remove the grease and then wiped dry; being afterwards lifted to a bench and rolled along to the adapter fitting department. The section of the plant where the adapters are made adjoins the fitting department, and a description covering their manufacture will be found near the end of this article.

Fitting and Screwing in Adapter

The shells on arriving at this department are first of all weighed. Any shell that shows a little too heavy or light, as the case may be, is corrected by putting in a heavy or light adapter. The latter are fitted into the base as they must be a good fit at the shoulder. The two drive holes in the adapter are then drilled out to ¾ in. for the wrench used for screwing it into the base. The adapter is screwed into the base and then withdrawn to see if it has seated.

Previous to being screwed finally into the shell, putty is applied to the pilot or clearance of adapter and the threads are covered with Pettman's cement. As will be observed in the illustration, the shell is held securely in a vise on the floor, while a gang of men with a long wrench screw the adapter home. The base is then examined by a Government inspector and the shell is taken over to the air hammer to have the joint closed up. A circular plate having a number of holes is laid on top of base of shell, which is held in a vise nose down. The holes in the plate guide the hammer and keep it on the line all round while riveting.



APPROXIMATE FORGING SIZES OF 9.2 INCH HOWITZER SHELL.

Copper Band Operations

The shell is now ready for the copper band which is secured in place by means of a press supplied by the West Tire Setter Co., Rochester, N.Y. The press has twelve cylinders with plungers operating in a horizontal direction, converging towards the centre and distributing the pressure uniformly. The plungers are operated by oil pumped from a vertical belt driven plunger pump. The operating pressure is 2,500 lbs. per sq. inch. One of the illustrations shows the band press and hoist for handling the shells. It also shows the electric band heaters on the right hand. An essential feature of this operation is that the band shall completely fill the groove and undercuts. To ensure this it is necessary to heat the band to make it more ductile. There are three Ferranti electric heaters installed, designed specially for this particular class of work. The heater consists of a transformer core and primary winding, the shell band forming during the time of heating the secondary of the transformer. The yoke of the transformer is made so that it swings out of position on an arm, thus allowing the band to be placed around the primary winding. The primary winding is protected from the heat of the band by a cylinder of refractory material on a shelf projecting from which the band rests. When the heater is switched into circuit a current of 45 amperes at 550 volt. is induced in the shell band. The time necessary to bring the band to a bright, cherry red heat about 1,500 degs. Fah., is approximately 4 minutes. The copper band weighs 13 lbs. 12 ozs. The inside diameter is 9.085 inches, outside diameter 10.275 inches, and width 2.525 inches.

The copper bands are machined in three "Conradson" 28-in. x 10 ft. engine lathes equipped with a "Phoenix" turret tool post. There are four tools in the tool post. The first roughs the band, the second is a rough forming tool, the third is the finishing tool, while the fourth tool cleans up the outside edges of band. The forming tools are of steel of special design to conform to the shape of the copper band. The base of shell is held in a special chuck, and a centre is screwed into the nose end. The shells are lifted to the lathe from the runway by a chain hoist and, when the operation is completed, are swung over to the bench behind the operator.

EMPLOYEES' SPECIAL TRAIN, MORNING AND EVENING, TO AND FROM THE PLANT.

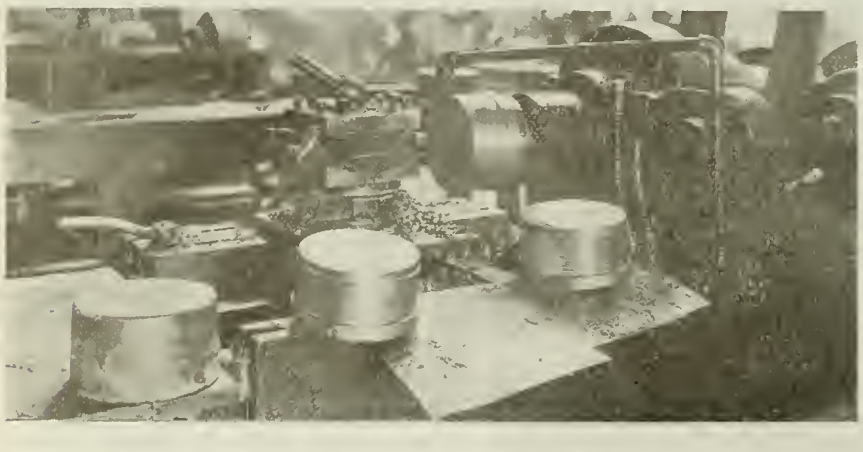
Facing Base and Adjusting Weight

The shells are rolled along the bench from the band turning lathes to the next set of machines for the base to be faced up. On the way they are weighed and the platform of the scales being flush with the bench no lifting is necessary. The weight of shell at this stage can be adjusted to bring it within the prescribed limits. The base is rough, caused by the peining or riveting after the adapter was screwed in. The facing operation, therefore, cleans it up and reduces the weight of the shell as necessary. The amount of metal removed varies, but it is usually only a light cut. The machines used for the facing operation are "Davenport" lathes, of which there are three, each having a "Phoenix" tool post. The tool post carries two tools, one for facing up the base and the other for rounding the corner of shell. For this operation the shell is held in a specially designed pot chuck, the base end being carried in a steady rest. The view of the rectifying department shows the layout of benches, scales and facing lathes beyond.

Rectifying and Finishing Department

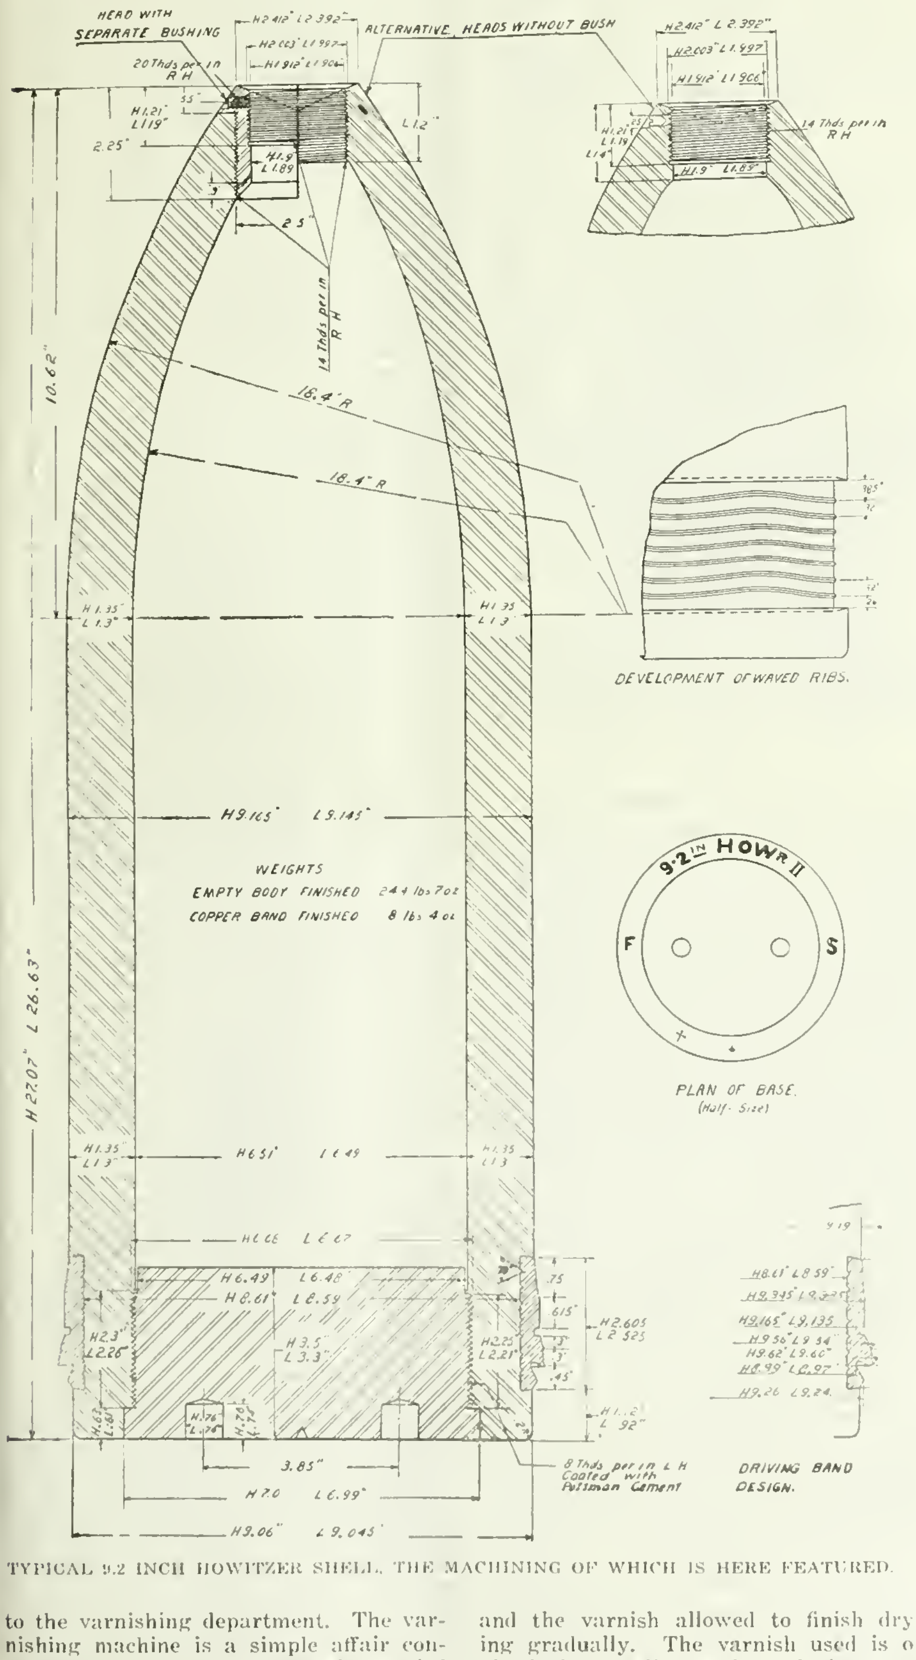
After the base has been faced up, the shells are again weighed and, if correct, are taken along to have the recess in nose finished in a lathe. The shells are next moved along to a bench where the inside is cleaned up. An examination is made for flaws, and cement or any other material that might have been retained inside the shell is removed. The base is then stamped with the various markings, including size of shell, mark IX., initials of firm, date of manufacture, and heat number of adapter forging. The heat number of shell forging is stamped on the nose profile after the finish turning operation being transferred from the base.

The next thing to be done is to hand tap the nose threads and clean up the nose bevel or fuse seat. The shells at this stage have compressed air blown in



FINISH TURNING ADAPTERS, AND SHOWING THE LATTER IN VARIOUS STAGES OF MANUFACTURE FROM FORGING TO FINISHED PIECE.

to remove chips, etc. They are afterwards rolled along the bench down the shop to be inspected by Government officials who carefully gauge, weigh and examine each shell. After being inspected, the shells are moved along the bench to the varnishing department. The varnishing machine is a simple affair consisting of four wooden wheels carried on a frame on top of the bench and driven by a belt. While the shell is resting horizontally on the rollers, it is rotating, the varnish being applied with a brush. The varnish is partially dried with compressed air, the shells being afterwards placed on the bench, nose up, and the varnish allowed to finish drying gradually. The varnish used is of air drying quality, and no drying oven is, therefore, necessary. The shells are again inspected, a plug is screwed in the nose and the outside greased. They are then boxed ready for shipping.



TYPICAL 9.2 INCH HOWITZER SHELL, THE MACHINING OF WHICH IS HERE FEATURED.

Machining Adapters

The section of plant where the adapters are machined adjoins the adapter fitting department. The adapter is a solid steel forging having the following finished dimensions: Diameter over pilot, 6.48 ins.; over threads, 6.67 ins.; and flange, 7 ins. It is 3.4 ins. thick, the flange being .62 ins., the threads 2.23 ins., with the pilot making up the remainder of the thickness. The first operation done on the adapter is roughing the face and body as far as the shoulder. Four "Davenport" lathes are installed for this work, each being equipped with a special fixture holding two tools. The fixture is in the form of a right angle having a tool at the end of each leg. One tool faces the end while the other tool rough turns the body. The chuck used for this work is much like a universal chuck rebuilt. It has a steel ring around the outside diameter of chuck with set screws for holding the work.

The next operation is rough turning the flange and base. This work is also done on four "Davenport" lathes with a tool post holding one tool. The chuck is similar to the one referred to above, only deeper. The two drive holes are drilled in the base on a "Barnes" drill. For drilling, a jig is placed over the base of adapter to get the holes in the right position. The holes are drilled for a ⅝ in. tap, and one is used for holding the adapter in the lathe at the finish turning and thread milling operations, the holes are tapped on a drilling machine equipped with a reversible tap in which the depth of feed is regulated by a safety appliance.

For the finish turning operation, four 22 in. x 10 ft. "Davenport" lathes are installed, each having a "Phoenix" turret tool post. The adapter is held to the face or drive plate by two set screws which are tightened up behind the drive plate. There are three tools in the tool post. The first finishes the face of the adapter, the second finishes the body, while the third forms the recess under the flange.

There remains only the threads to be milled on the adapter body. The machine used is in many respects like a "Holden-Morgan" plug miller, and was "adapted" by that concern for this particular work. The adapter is held in the machine by two long bolts carried through the drive head and screwed into the drive holes in the base of adapter. The adapter base is tightened up against the drive head of the machine. As in the case of other thread millers, the work makes one revolution while the hob is cutting the threads. The milling hob has, of course, an independent drive. The threads on the adapter are 8 to the inch, left hand. This operation finishes the adapter with the exception of the drive holes which are later drilled out to ¾ in. The adapters when finished are carried over to a bench in the fitting department to be screwed into the shell base.

Tool Room

Adjoining the main shop is a well equipped tool room for making and repairing tools, cutters, boring heads, etc., and also for shop repairs. The high cost and one-time scarcity of high speed tool steel, prompted the company to economize in the use of this material. The problem was solved by welding small flat pieces of tool steel to a mild steel shank. This is done in the blacksmith shop near to the tool room.

An important feature, particularly for a munitions plant, is the fire protection system. At various points throughout the plant are glass break boxes, connected to an indicator in the boiler room which shows the location of the alarm. Standpipes with fire hose outfits are located at various points, and a volunteer brigade from both day and night shifts has been formed to meet any emergency. The compressed air installed in the plant is supplied from a steam driven compressor in the boiler room. The line shafts are motor driven, the machinery being arranged in groups.

The location of the plant is such that unusual methods had to be resorted to in order to obtain employees. As there are no houses in the vicinity and only a few within a reasonable distance of the plant, accommodation had to be provided on the job, so to speak. An upper floor of one of the buildings was fitted up as a bunk room, mess room, and kitchen. In the bunk room there is sleeping accommodation for over 150 men. In addition to this, a train chartered by the firm takes employees from a distance back and forward, making two round trips per day, for the day and night shifts.

WORKMEN'S COMPENSATION BOARD REPORT

THE report for 1916 of the Ontario Workmen's Compensation Board, issued recently by Hon. I. B. Lucas, Attorney-General, shows that the compensation for the year, including estimates for continuing disabilities and outstanding accidents, amounts in Schedule 1 industries to $1,971,675.63, and in Schedule 2 to $451,709.93, making a total of $2,423,385.93, or an average of $7,800 for each working day of the year.

This is a heavy increase over 1915. The compensation in Schedule 1 for 1915 was $1,091,020.43, as against $1,971,675.63 for 1916.

Up to December 31 last, 16,192 accidents happening during 1916 had been compensated, 256 being fatal cases, 1,418 permanent disability cases, and 12,896 involving only temporary disability. The corresponding figures for 1915 were 9,289, comprising 251 fatal, 1,034 permanent disability, and 8,544 temporary disability cases.

The total assessments in Schedule 1 for 1916, including estimated adjustments, amount to $1,948,040.85.

These are contributed by 15,200 employers upon pay rolls aggregating approximately $183,000,000, representing the wages of about 240,000 full-year workers.

IMPERIAL MUNITIONS BOARD ORDERS

THE total value of orders received by the Imperial Munitions Board in Canada is $850,000,000, according to a statement furnished the Minister of Finance by J. W. Flavelle, head of the Commission.

The value of munitions shipped to March 30, was $470,000,000, while the total disbursements to March 30, were $543,000,000. The number of employees is divided as follows: Headquarters staff 800; inspection, 4,000; workers, direct and indirect, 250,000 to 300,000. Six hundred and thirty factories, chemical and loading plants are in operation in carrying out the orders of the Board. The products covered by these orders include shells and their component parts. which represent an immense tonnage of steel, brass, copper, lead, etc. They include propellants and fuses, also ships, locomotives and cars. An idea of the financial magnitude of the business is obtained from the fact that the cash disbursements for March were $41,000,000, and will be for April $43,000,000.

Towards the financing of the business the Dominion has contributed $200,000,000 as a loan to the Imperial Treasury, and arranged with the Canadian banks for advances aggregating $100,000,000.

LOAN TO ASSIST SHIPBUILDING

THE Imperial Munitions Board has accepted the offer of Sir Thomas White to make a special loan of ten million dollars to assist in the development of wooden ship building in Canada. Orders have now been placed for steel ships in Canada up to full limit of the steel plants available during the next fifteen months. In view of this, and the need for constructing every possible ship, the question of developing wooden ship building has been under investigation during the last month, and it has been represented to the Imperial Government that a substantial tonnage of suitable vessels could be obtained.

Specifications and designs of the type of wooden vessels required have been under discussion between the Imperial Munitions Board, the representative of the British Minister of Shipping and the various shipbuilding firms. These are now almost complete and will be avail-as a standard pattern of design. It is hoped to begin work on vessels of this type soon, and the building of a considerable number will be arranged for in Canada, probably for the most part on the Pacific coast, where suitable lumber is available, in abundance.

Priming is the carrying of water from the boiler, in the form of spray, with the steam into the main steam pipes. It is caused by restricted steam space, poor circulation and the forcing of the boiler beyond its normal capacity.

GRINDING OF TAPERS.

By J. Spence.

A TAPER, either internal or external, is a most difficult thing to measure with a micrometer. In ordinary shop practice, master gauges are used that have been carefully machined to the correct taper, and either chalk, Prussian blue or red lead is ligthly rubbed on the gauge, if it be a plug gauge, or on the work if it be a sleeve gauge, and the correctness of the bearing judged by the evenness in which the material is rubbed from the gauge, or work. If a sleeve gauge is used on the work, and a slight turning motion be given the piece, and the material is rubbed from the work the whole length of the taper, then we are sure we have obtained the proper setting of the machine. If the marks indicate a heavy bearing on one end only, and none on the other, then we know that our taper is wrong and proceed to correct it from the given clue. Chalk is seldom used to ascertain the truth of a taper in present grinding practice. It is still used, however, to some extent, in lathe work.

The Norton Grinding Co. use red lead entirely throughout their plant in fitting tapers to a gauge, whether the gauge be a plug gauge, as used for internal grinding, or as a female gauge as used in cylindrical grinding. A great number of factories throughout the country use Prussian blue altogether. The advocates of Prussian blue are just as positive of the merits of the blue as we are of the lead. To any one brought up to the use of red lead, the change over to the use of the blue is rather embarrassing for a time. The writer has used both to a considerable extent and is strongly in favor of the use of red lead. It hardly seems possible that any one who has properly applied correctly prepared red lead a single time would go back to any other medium in the fitting of tapers.

To a quantity of dry red lead, just enough oil should be added to make the particles of lead adhere together when firmly pressed. It is a mistake to put in more oil than just enough to dampen the lead. The oil should not be visible, and when mixed properly the lead should have the consistency of partly dry putty. An excess of oil, even to a slight degree, may give a deceptive bearing. The container should be covered when not in use to keep out all particles of dust and grit. The red lead should be spread upon the work in cylindrical grinding, or upon the plug gauge in internal grinding, very lightly so as to show nothing but a very thin film, or bloom. In this way only can a delicate bearing be obtained.

Prussian blue has a tendency to smear. It is difficult to spread the film evenly and quickly without showing an unevenness in film covering. It is this uncertainty in thickness of film that makes it objectionable to one accustomed to red lead. It is sticky and adheres to the surface so firmly that it is somewhat difficult to wipe off quickly before attempting another trial bearing. In the grinding of a long, small diameter-tapered hole this is intensely apparent to the grinding machine operator if he attempts to wipe out the hole before taking a second verifying gauge-reading.—*Grits and Grinds.*

PRODUCTION METHODS AND DEVICES

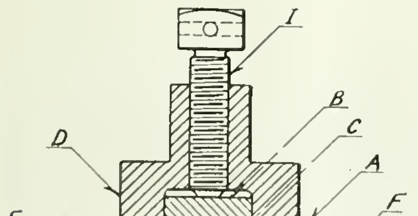
HAND-SIZING COUNTERBORE FOR 8-INCH ADAPTERS

By R. Hamilton.

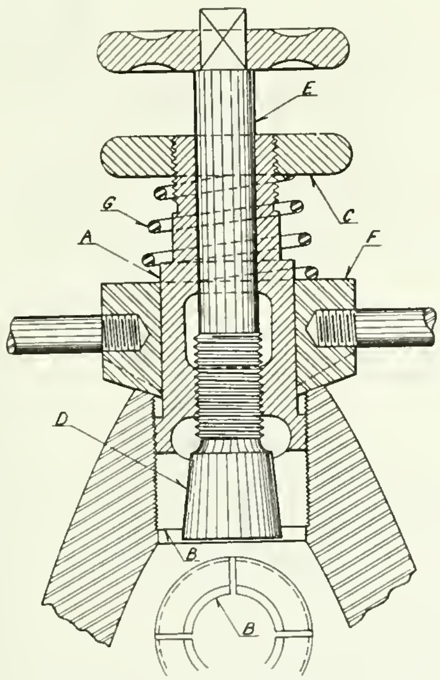
FITTING adapters in the various types and sizes of shell is a very important detail in the manufacture of munitions. It is highly essential that this portion of the assembled shell should be made to fit as accurately as possible in order to prevent the passage of gas, from the propelling charge to the charge in the shell, at the time the projectile is discharged from the gun. While the necessity for careful fitting is obvious in all cases, it is more pronounced in the larger sizes, where the various diameters of the adapter and shell bore increase the tendency to develop defects in the machining that may subsequently interfere with the assembling operation. Many methods have been adopted to eliminate the eccentricity of the several diameters, but complete success has not yet been established. Where the base operations on the shell or adapter are accomplished at one setting, the variation in alignment becomes less pronounced, but when the counterbore and recess and the cutting of the threads are performed at two separate settings, the danger of eccentricity is greatly increased. Where, in addition to this, the turning of the adapter and the threading of the same are similarly accomplished, it is practically impossible to obtain a clean fitting adapter.

The tool here illustrated was designed to assist in the assembling of the 8-inch shells, where it was found that the



HAND-SIZING COUNTERBORE FOR 8-INCH ADAPTERS.

thread portion and the counterbore were not concentric with each other. The cutter A, which is six inches across the cutting face, is secured in the piece B by means of the grub screw C. This piece B is four inches long, providing ample length for stability. It is a free sliding fit in the tool steel spindle D; this



RESEATING REAMER FOR FUSE SEATS.

spindle in turn revolves in the brass bush E fitted to the bore of the large cast iron bush F. The entire device is secured as a unit by the flanged collar G secured to the lower end of the spindle. To operate, the bush is screwed into the base of the shell so that the upper surface comes just below the bottom of the counterbore. Two styles of bushes were found necessary, as shown by the sketch. When firmly in position, the spindle is revolved by means of a double-end wrench placed on the square at the top. The slot in the spindle allows the cutting tool to be moved downwards by operation of the feed screw I. After the cut has been completed, the tool is returned to its initial position by the backing of the feed screw, the reaction of the spring H forcing the tool block upwards.

RE-SEATING REAMER FOR FUSE SEATS

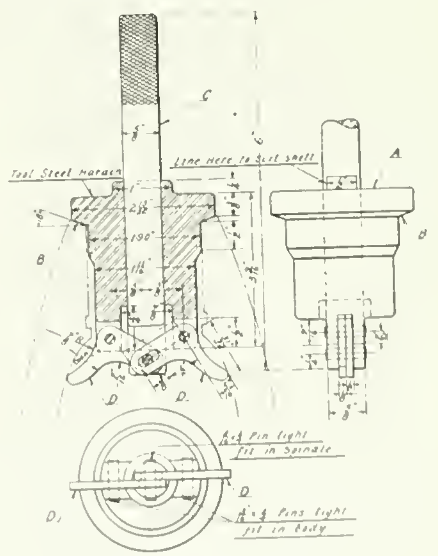
By J. H.

AN important essential in connection with the finishing operations on all sizes of shell is that of re-facing the nose to insure a perfect fit between the fuse and its seat. Owing to the possibility of this portion being subjected to damage during its transit from one place to another, either from carelessness or otherwise, it is deemed necessary to give it a final facing previous to its being crated for shipping. This may be done at any time after the last machining operation, but it is better accomplished just previous to being packed. The sketch shows a device developed by the Imperial Munitions Board for performing this operation. The housing or outer spindle A is threaded on the lower end to fit the fuse thread in the nose of the shell, and is afterwards split, as shown at B. When screwed to position, which is accomplished by means of the handle C, the split portion of the outer spindle is expanded by the action of the cone D on the lower end of the central spindle E; the operating threads being left-hand. The face milling cutter F, operated by the handles shown, is fed by the light spiral spring G, this spring being of the spiral type to permit of raising the cutter to inspect the condition of the face.

AN INTERESTING SHELL GAUGE

By M. O.

DIFFICULTY is often experienced in determining whether the inside profile is of the required dimensions and in the proper position relative to the other portions of the shell. Owing to its location, accurate gauging of the inside contour is a factor generally solved by the shape and adjustment of the cutting tools, so that suitable stops will determine the machining of this section of the shell. To assist, however, in attaining more uniform results in connection with this operation, the Jenckes Machine Co., Sherbrooke, Que., designed the gauge shown in the accompanying sketch; simplicity and efficiency being two of its principal features. The body A is made



AN INTERESTING SHELL GAUGE.

to fit the finished nose of the shell, the sizing diameter being a free fit for the threaded portion and the bevel part B turned to an angle of 18 degrees, to fit the fuse seat. The spindle C is a sliding fit in the piece A, and is slotted at the lower end to receive the operating end of the two bell cranks D, which in turn are fulcrumed in a slot cut in the end of the piece A. The device is shown in gauging position, graduations being placed on the spindle above the piece A, to indicate same. By lifting the spindle C, the two bell cranks are swung inwards, this being permitted by the location of the slots in the operating end: the gauging points will then clear the thread diameter and the device is easily taken out. This gauge can be used while the shell is still held in the chuck.

WHY A PATTERN IS DIVIDED

By D. A. Hampson.

IT is very hard to get designers and patternmakers to divide their patterns, probably because few of them take the trouble to obtain the moulders' viewpoint. A mould is made in a box called a "flask," that is split horizontally, and in which the pattern has been placed ond the sand packed around it. Now note, to get that pattern out, the halves of the mould have to be lifted off the pattern, or the pattern has to be lifted out of the mould; there is a vast difference,

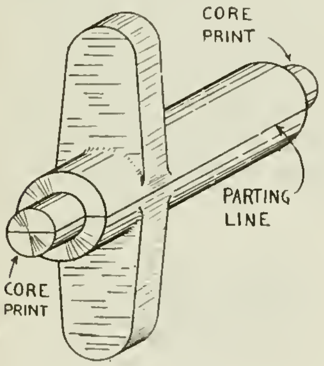


FIG. 1

and on this difference hinges the reason for divided patterns.

As an example, consider the pattern in Fig. 1, which has a deep lug extending on opposite sides of the hub, and core prints at the ends. Assuming that this pattern were made solid, and that we could look into the mould before the pattern was "drawn" (out), we would see something like Fig. 2. The parting line is marked; it is the line between the upper and lower halves of the mould, known respectively as the "cope" and the "drag." In order to get the pattern out of the mould, the cope has to be lifted off the pattern, the latter remaining in the drag if the moulder has good luck. The pattern has in all six vertical faces, and the trick is to lift the cope off so that none of them knock off any sand—a practical impossibility. The rounded hubs and the tapering sides of the lug draw without any trouble, but the vertical faces, even though made with the usual "draft," are sure to catch portions of sand and spoil the mould so that patching up is required. When it is considered that this cope may be a box 18 or 20 inches square, and 8 or 10 inches deep, and weighing up to a hundred pounds, the proposition of a man lifting it 5 or 6 inches in a perfectly straight line, never raising one corner

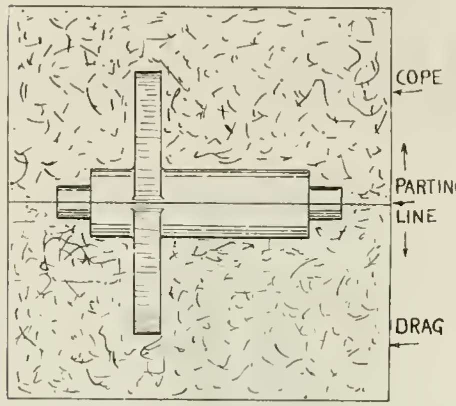

FIG. 2.

ahead of another, is a formidable one. And while he is doing this, he cannot possibly see underneath to gain an idea as to "how she is coming."

Advantage of Splitting

If the pattern be made divided, the patternmaker predetermines the parting line of the mould when he splits his pattern. The pattern in Fig. 1 is split along the horizontal centre line, as noted. To keep the halves in relation, two dowels are put in, one flat face, and enter holes in the other. To facilitate the moulder's work the dowels are made with a good deal of taper, and only fit the holes exactly when the two halves are in actual contact.

Now the divided pattern is put in the flask and has the sand packed around it, just as does the solid pattern shown in Fig. 2, but here the similarity ends, for to get the pattern out of the sand the cope is lifted off and carries with it one-half of the pattern, as shown by Fig. 3. The dowels offer no resistance, and there is no sand to disturb. Then this part of

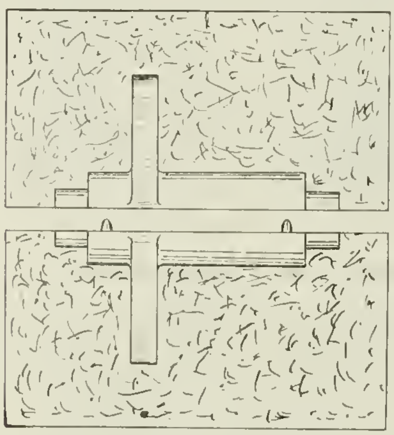

FIG. 3.

the mould is inverted and becomes for the time being just as the other half. It is a comparatively simple matter to draw the pattern out of the sand when only the pattern has to be lifted; it of itself is light, and the whole operation can be seen. Hence, easier work and quicker, and no patching up to be done. The half pattern can be jarred in the sand ("rapped" it is called), making the space in the sand the least bit larger than itself and removal is a simple operation. In Fig. 4 the half pattern is partly withdrawn.

If the work is rightly planned, divided patterns are as quickly made as solid ones. Because the work is arranged so he can see it, the moulder needs less draft than with solid patterns, and this is a point appreciated by the men in the machine shop who have to work up the castings. When there is a doubt as to where or how to divide a pattern, the moulder should be consulted.

COATINGS FOR WOOD PATTERNS

By D. A. Hampson.

SOME plants have specified colors for different parts of their patterns. The ground work is natural wood finish, core prints are black, and surfaces that are to be machined are red. While this is only a typical color scheme, it serves for an example, and the moulder knows at a glance just what the casting will be and how it will be worked up in the shop.

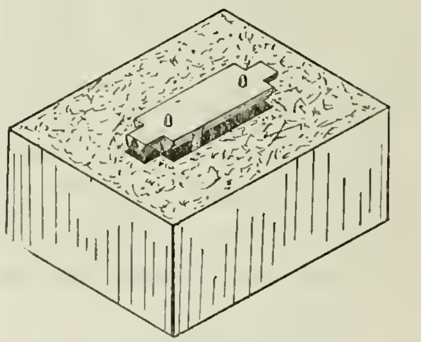

FIG. 4.

But whatever the color scheme, shellac is the basis of the coating, and the various colors are obtained by mixing powders in the clear shellac. Many plants paint their patterns black, and to get that, mix lampblack in the shellac and thin with denatured alcohol.

The present high cost of shellac has brought into prominence one or two very good shellac substitutes, which fill the purpose well, but take a longer time to harden than shellac. It should be borne in mind that the purpose of the coating is primarily to protect the wood from the destructive effects of the damp moulding sand. Holes and imperfections in the wood surface are commonly filled with beeswax; small fillets and corners are formed from it. Paraffine wax is much cheaper and just as good, but patternmakers have trouble in making it stick to the wood. If the pattern is given one coating of shellac first and then the paraffine applied hot, it will stick as well as beeswax.

ADAPTING GASOLINE ENGINES TO BURN KEROSENE

By H. P. Hoag

AS THE price of gasoline advances the interest in the cheaper fuels for the gas engine increases and some experiences the writer had in adapting a line of standard gasoline engines to burn kerosene and naptha may be timely. The experiments covered a period of nearly two years before the following points were finally settled on. 1st: It was found that heating the air entering the carburetor reduced the power of the engine to a very marked degree. 2nd: To give best results, kerosene and naptha should be heated nearly to the evaporating point before passing the spray nozzle. 3rd: Water must be admitted into the carburetor with the fuel to retard the burning and give smooth running.

Heating the air was advocated by a number of writers but it was found after trying out many hot air devices, some home made and others from abroad, that in every case the power of the engine dropped, in some instances to but 70 per cent. that of gasoline, so that the hot air idea had to be abandoned altogether, as the manufacturer could not send engines out that would not develop their rated power no matter how well the oil was burned.

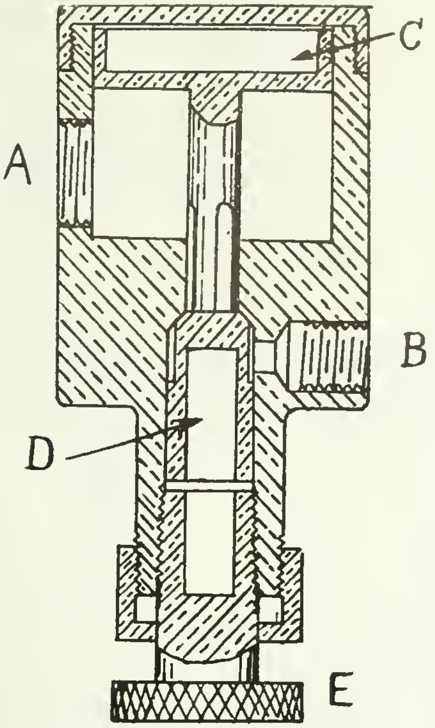
Fuel Heated

Heating the oil was accomplished by providing a separate chamber around the outside of the fuel reservoir in the carburetor through which water is circulated, this water being taken from the hottest part of the cylinder jacket. By this means the fuel is kept at the proper temperature and is warm enough by the time the engine is ready to turn on the kerosene; gasoline is used to start with.

Spraying water into the mixture gave a good deal of trouble, that is to get the proper amount for each charge, because when using a throttle governor it became evident that a fixed amount of water for each charge was not the thing, but that the quantity of water should vary according to the load or the amount of fuel taken in. Some means to automatically prevent water running into the cylinder when the engine was shut down was also required, as the operator could not be depended on to turn water off each time.

Use of Automatic Valve

To embody the above requirement the automatic water valve shown herewith was designed, the construction being as follows. In the upper chamber of the valve body there is an air piston C which extends down onto the small inverted valve D. The valve being held up to place by a light spring (not shown) placed inside the valve and the hollow adjusting screw. The opening A is piped into the carburetor between the spray nozzle and the throttle valve. Opening B is piped to a convenient place in the water jacket with a stop cock in the line for shutting off the water when using gasoline. The action is as follows, (the upper chamber being in communication with the carburetor): when suction takes place the piston C is drawn down against valve D, forcing it away from



AUTOMATIC WATER VALVE.

its seat by a varying amount according to the load on the engine, when the necessary amount of water flows past the valve D then the pipe from A into the carburetor entering the cylinder with the fuel. It will be noticed there is a fine threaded adjusting screw provided at the bottom to set the stroke of valve D to suit the size of the engine. It is obvious that with this device the quantity of water is varied according to the load also that no water can get past valve D into the cylinder when the engine is not running. With this arrangement it was found not only did kerosene burn(in the ordinary gas engine) as well as gasoline but usually eight per cent. more power was developed with the cheaper fuel.

SAVING TIME ON SCREW MACHINE WORK

By D. A. Hampson.

IN the manufacture of small arms, great quantities of screw machine parts are turned out automatically. One piece to be considered is shown at Fig. 1. It is of 3-16 in. mild steel, and has a ⅛ in. hole drilled clear through it, and, while still in the automatic screw machine, the slotting attachment put the 1-32 in. cut through one end. This latter was very hard on cutters, the walls being so thin that the teeth of the cutters were broken in a very short time. The cutters had the standard shape of tooth, as in Fig. 2, and, though regular screw slotting cutters were tried, they fared no better.

Production on the automatics was reduced 5 per cent. by the delay in changing cutters, and the latter had to be bought by the hundred. In trying to better the output, this operation was taken off the screw machine and put on a milling machine, and while it speeded up the work of the former to the right point, the slotting job was as expensive as before, even though the feed of the milling was made specially low in an attempt to prevent "raking" out the teeth.

The whole trouble was solved, as shown in Fig. 2, right-hand side, by grinding the teeth almost entirely away. There is then very little space to catch on the narrow work edge, and the teeth are so stubby that they cannot be broken. One such cutter was usually good for 11,000 pieces before sharpening.

Another mild steel piece made on the automatic is the cap, Fig. 3, with a small, deep, blind hole tapped in it. The production was 1,600 per day untapped, or 900 tapped, the difference being the time spent in renewing broken taps and in running the tap and backing it out, which, of course, was done at a reduced speed. So the tapping was taken off the automatics and put on a $16 bench drill provided with an Errington tapper. A laborer was here able to tap as fast as the automatic turned the caps out. Moreover, the breakage of taps was not more than one-twentieth of what it was in the more expensive machine, and this latter was kept running at high speed, with no slow down for each piece.

SAVING TIME ON SCREW MACHINE WORK.

RE-TAPPING SHRAPNEL SHELL SOCKETS

By J. H. R.

TO eliminate the possibility of an undersized thread, due to the continual wear on the machine taps, all threads are generally hand-tapped after the shells are assembled and the sockets screwed to a permanent position. As the

RETAPPING SHRAPNEL SHELL SOCKETS. G.T.R. SHOPS. MONTREAL.

actual operation of tapping the hole takes but a small percentage of the total time occupied for each shell operated on, it is an important factor of production to provide means that will reduce the handling of tools to the lowest possible medium. While on a recent visit to a shell plant, the writer noticed the simple device here illustrated, and which has assisted somewhat in the solution of the unproductive factor. Fitted to the stand that supports the shell chuck is a plate that extends up and above the floor stand. Midway up this plate is secured a bracket A, through which the rod B passes freely. The axis of this rod is in line with the centre of the shell, thus aiding in entering the tap into the thread. To the upper end of the rod the chain C is secured, which in turn passes over an overhead pulley and connects with the balance weight D. The device is shown in the operating position, and when not in use is suspended at a short distance above the shell, the tap always remaining in the dumb-bell wrench E.

WOMEN AND MUNITIONS

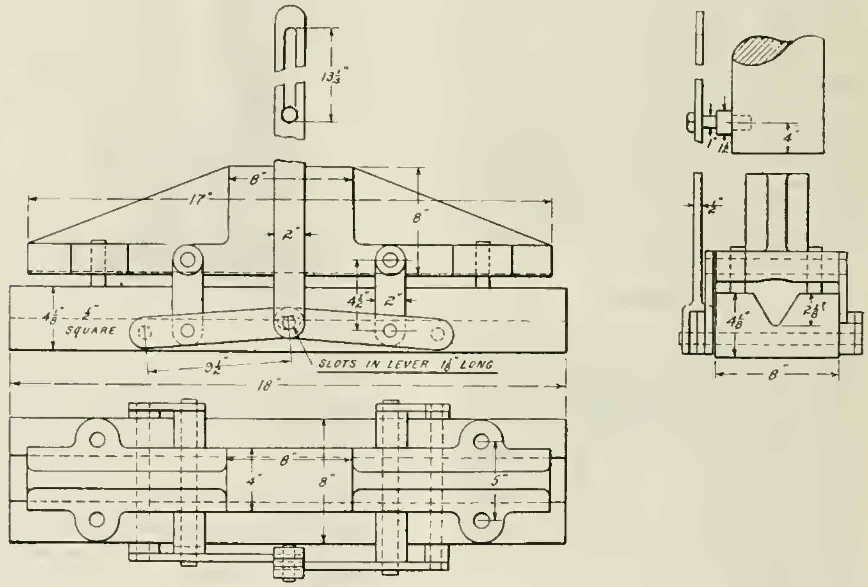
By B. S.

THE introduction of women into the sphere of munitions work has necessitated the adoption of certain methods that would eliminate much of the labor contingent to the production of the various types of shell. In many respects the weaker sex (physically) have quickly adapted themselves to the changed environment, and are rapidly becoming an asset to the shell-making industry. Much credit is due to those women who have recognized the needs of an unprecedented situation and adjusted themselves to an occupation that in normal times might be considered beneath their dignity. The illustration herewith shows a Montreal girl at work in one of the munition plants operating a vertical milling machine facing the base of shrapnel shell. A multiple jig holding six shells is secured to the table of the machine, the cutter working continuously upon the upper surface. The operator is seen securing the clamp upon two shells just placed in the jig. As the shells are light, a small hand clamp is provided for removing the greasy shells from the fixture. The production from this machine is approximately 30 shells in 10 hours.

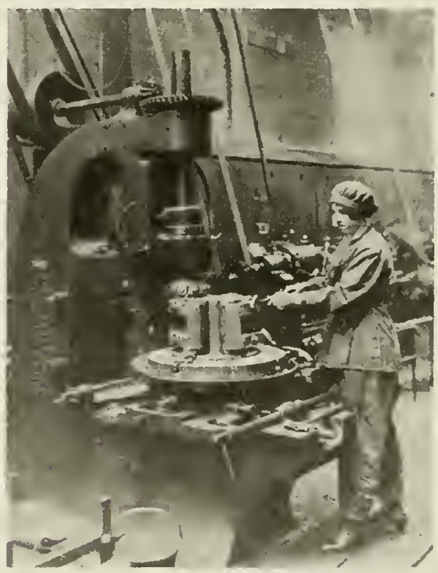
DIES FOR STEEL PILOT FENDER RAILS

By S. P. Y.

IN the manufacture of steel pilots, old boiler tubes are used for the rails, the section being changed to triangular by means of a die similar to that shown in figure in order to provide additional stiffness. The die shown is one that can be placed under any press of the required capacity, the only connection to the press being the stud on the ram at the correct point to raise the die clear of the job after it has been done, sufficient room being left so that a quick removal can be made .



DIES FOR STEEL PILOT FENDER RAILS.



WOMEN AS MUNITIONS OPERATOR IN G.T.R. SHOPS. MONTREAL.

DEVELOPING OUR LATENT WEALTH

THE Honorary Advisory Council for Scientific and Industrial Research has received reports on many subjects under investigation. Among these are the problems of "the manufacture of nitrogenous fertilizers," "the production of potash from feldspar and other raw materials by various processors," the utilization of the tar sands of the Athabasca region," "the manufacture of oil and other products from oil shales," and "the smelting of iron from iron ores mined in the Dominion" in order to substitute these so far as possible for the ores now imported for different purposes. At present no less than 83 per cent. of all the iron ore smelted in the Dominion is imported.

The Council has also under consideration the question of the uses to which the plants built for the production of munitions of war in Canada may be put, upon the cessation of hostilities. Among the other questions which are under consideration, is a more efficient use of the agricultural lands of the Dominion, and the problem of making the great mass of information concerning the "natural resources of the Dominion" now in the archives of the Government departments more readily available for public use.

Not Her Job.—He was a young subaltern. One evening the Sister had just finished making him comfortable for the night, and before going off duty asked:

"Is there anything I can do for you before I leave?"

Dear little Two Stars replied: "Well, yes! I should like very much to be kissed good-night."

Sister rustled to the door. "Just wait till I call the orderly," she said. "He does all the rough work here."

Tool Holder and Cutting Tool Application Data--II.

By F. Scriber

The approaching return to broader and more general lines of manufacture render a study of tool-holders very timely. While the welded tip has found considerable application under recent conditions of heavy duty and unskilled operation, the obvious advantages of well designed tool-holders are such as to insure a continuance of their use, more especially where variety of work offers increased efficiency opportunities for well assorted equipment.

MANY tool holders have been developed with the idea of establishing a fixed angle of rake, and, in fact, tool holders may be classified largely with reference to this. For instance, there are the holders which retain the blades at a fixed cutting rake; there are those which maintain the blade at a fixed clearance angle, and there are those holders which provide for neither of the foregoing; in other words, they hold the cutter straight.

Mention was made in the preceding article that the blades were usually presented to the work by the tool holders either at right angles or to the right or left of this position, and, likewise, holders were shown in the illustrations which held the blades in these various positions. In Fig. 9 a holder is shown which presents the blade to the work with a fixed clearance rake, the cutting rake on the blade being obtained by grinding; in addition to this, the holder shown is of the swivel type, and the blade may be presented to the work at various angles by turning the head A to the position desired. In any position, the head is clamped by the nut B. The cutter C shown in this illustration is locked by means of the shoe D and screw E.

Tool holders, which are quite often used for planing, are illustrated in the other views of Fig. 9, namely, bolt clamped swivel holder in which the cutter F is clamped by nut G and bolt, while below

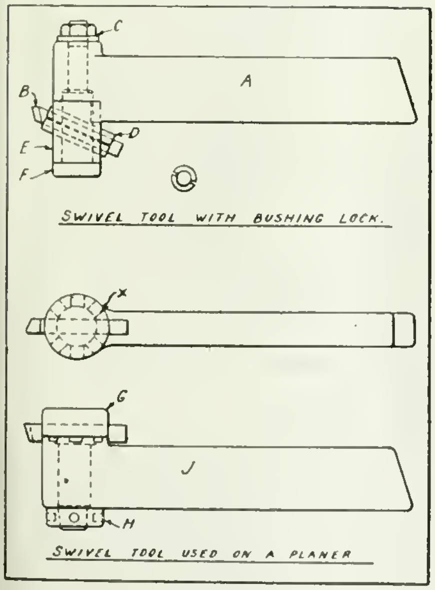


FIG. 10.

is an open side swivel holder, which is operated similar to the one above except that the blade J is held in a slot cut out of one side of the bolt. It will be noticed in this connection that the blade has the upper side bevelled, by means of

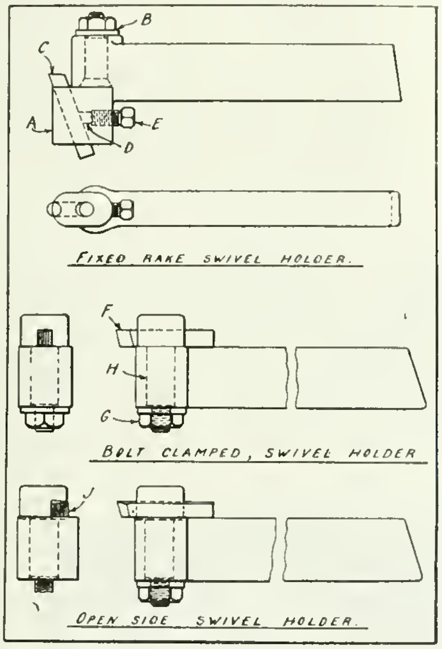

FIG. 9.

which the cuter is held securely against any tendency to side movement which might exist.

Bushing Feature

In the clamping of cutters in tool holders, bushings often play a large part, one advantage of these being that different sizes or shapes of cutters may be slipped into suitable bushings, and the bushing containing the cutter may then be slipped into the holder. Holders in which these features exist are quite varied; upper view, Fig. 10, shows one of these holders, and clearly illustrates the principle involved. Referring to the illustration, A represents the body of the tool, B the cutter, C the nut which binds the cutter in position, the bushing which holds the cutter being shown at D; this bushing as will be noted is split and may be turned to give the cutter proper side clearance. The cutter is held at the proper cutting angle by the bushing, and the clearance angle is ground on the cutter. The bushing with cutter in position is passed through another bushing E and the stud F, when, by tightening the nut C, the whole is readily clamped together against the bar. This tool holder is of the swivel type, and may be set at various angles. A holder which is largely used for planing is shown in the lower view of Fig. 10; this consists of the clamping bolt G and nut H with holder J. One slot is cut through the bolt G and, through this, the cutter is passed. In the holder J, four slots X are cut, from any of which the cutter may be presented to the work.

A simple and economical holder using milled blades is illustrated at the top of Fig. 11. In this holder the blade is clamped directly by the tool post screw, this being accomplished by placing a plate A on top of the blade while the cutter B is held in the formed holder C. This holder presents the blade at the proper cutting angle and permits of the minimum amount of sharpening; this sharpening is done on the front of the blade at Y. A holder which grips a curved blade is shown in the middle view of Fig. 11, the manner of holding the blade being obvious from the illustration, as the blade is clamped by a screw D at the top of the holder; this screw clamps the shoe E, which in turn clamps the blade. Under this cutter a form plate F is placed. With this method of holding the blade, it is apparent that there is a long gripping surface on the blade, which is often desirable when necking or cutting off work. This form of cutter provides for the necessary cutting rake, and thus the clearance angle only has to be ground on the cutter.

Referring to the lower view, Fig. 11, the blade and holder shown are used for the same purpose as the above. This holder is side opening, and the blade is

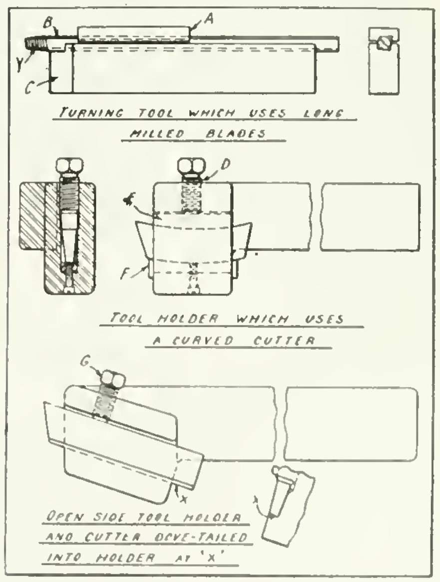

FIG. 11.

held at the proper cutting angle. The blade is also dovetailed into the holder, and is clamped by the screw G. A holder which carries square milled cutters, and is clamped by the tool post screw, and may be made to carry the cutter at the proper cutting angle, is illustrated by Fig. 12. This holder is made in two parts, the two parts being held together by dovetailed slots, as shown at A and B. When the cutter is in position in this

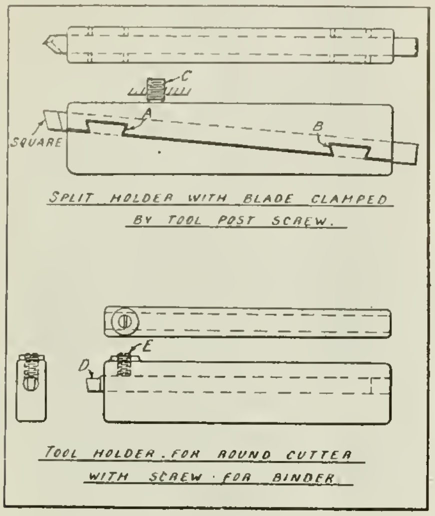

FIG. 12.

holder, the two halves will not come apart, and consequently the cutter is removed from the back of the holder when being reground. By tightening the screw C in the tool post, the cutter is gripped by the upper portion of the holder in the same manner as in clamping any tool holder. In the lower view of Fig. 12, a holder used for light turning operations is illustrated. In this holder the cutter D used is round and is clamped by a headless set screw E.

In Fig. 13 a number of types of cutting-off tools are shown. Cutting-off tools quite often have a tendency to dig into the work, and consequently the tool which holds the blade must be rigid enough to overcome this tendency. This digging-in is quite apt to happen when the work is almost cut off. Cutting-off blades are usually made of a narrow and deep section, the reason for this being that it is desirable to make the width of the cut-off portion as little as possible in order to economize in stock and, in doing this, the blade must, of course, be made deep enough to withstand the strain of cut.

The first illustration in Fig. 13 shows a built-up holder, this being made in two parts. The holder A itself is machined out to receive the blade B, while the plate C is screwed to the side of the holder to keep the blade in the slot. The blade in this holder is clamped in position by a set screw D, the latter being placed in the main portion of the holder, stock having been left in the holder for this purpose. The second illustration, Fig. 13, shows a holder for cutting-off which can be classed as a spring binding cut-off tool holder; the blade in this holder is clamped by the tool post screw, this being accomplished by having the holder slotted at E and F, thus making a holder which will spring together when the screw is brought down on top of it, thereby clamping the cutter. The filister head screws shown in this holder merely keep the holder in shape, so the blade is a sliding fit in the slot.

Referring to the third illustration in Fig. 13, the blade in this case is clamped by the strap G in the usual manner, a slot having been machined in the holder to receive the blade section shown in the end view. As this strap is tightened, it forces the cutter down into the bevelled set H under the cutter, and the upper bevelled side of the clamp J holds the upper portion of the blade securely against the side of the holder. In the lower illustration, Fig. 13, a holder is shown which clamps the blade at the side, the blade K in this holder fits the slot machined in the side of the holder, and is clamped in place by means of a screw L which is made to tighten the strap M by means of a bar N and the draw bolts P.

Some other types of holders which are of quite interesting construction are illustrated by Fig. 14. The upper views show a cutting-off blade A, which is clamped by a draw bolt B and a wedge-shaped piece C. In using this holder, the blade which fits the slot is put in place; following this the wedge C is placed in position, when, by tightening the nut D, the bolt forces the wedge against the side of the cutter, and also forces it downward, thus securely clamping the cutter in place from the side. The cut in the middle of Fig. 14 shows one view of a cutting-off tool supported by a bar which rests on top of the work being cut off. In this holder, the blade E is clamped by the set screw F at the side, the holder itself G being cut out to receive the blade. At the opposite side of the holder from which the tool is placed, a slot is cut to receive the right angle

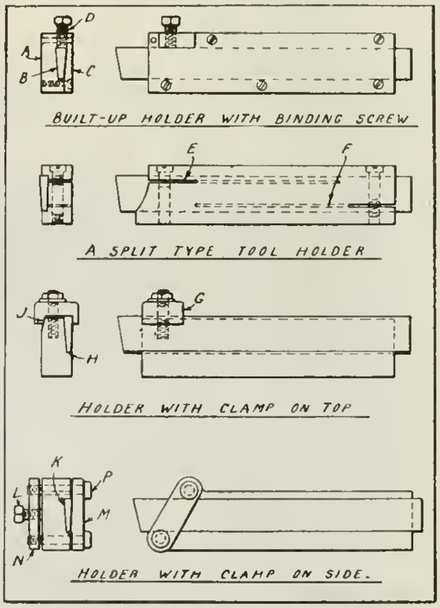

FIG. 13.

part H. Before starting to cut off, the surface X on the bar is brought into contact with the work by sliding this part up or down in the slot. When the bar is set in the correct position, it is clamped by the two screws J and K. The cutting-off tool is now operated in the usual manner, and the bar supports the part being cut in much the same way as would a back rest in turning.

The lower view in Fig. 14 shows a plan view of a holder, which may be

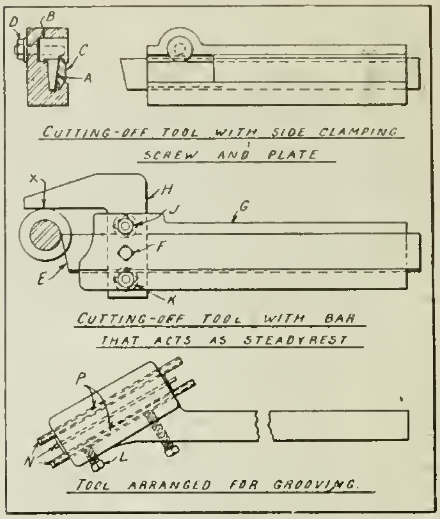

FIG. 14.

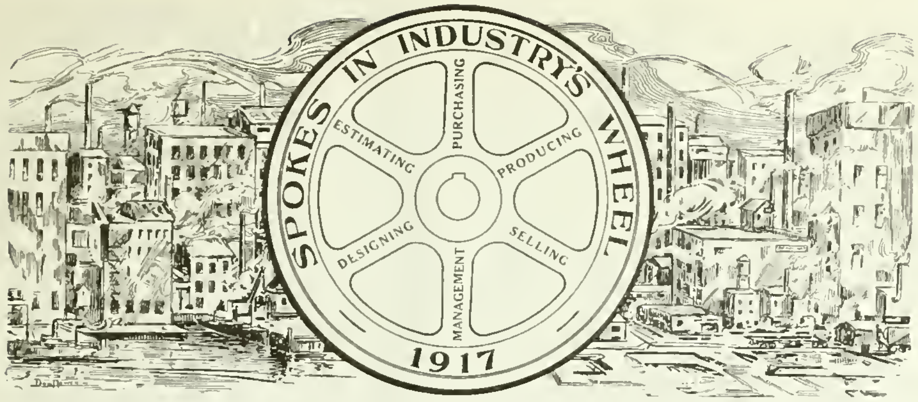
used for either cutting-off or grooving. The particular holder shown carries three cutters. These are narrow at the top and of deep section, the same as other cutting-off tools, and are clamped in position by means of the two screws L and M at the sides. The blades N are placed in the holder with spacers between them which hold the cutters the correct distance apart. The cutters and spacers are then, of course, clamped by the screws. When by placing the tool in the tool-post holder and operating in the usual manner, it can be used for cutting grooves or, by placing one cutter slightly in advance of the other, the holder will cut off two or more rings at the same time. The particular holder shown is of a type used for grooving pistons and contains three cutters, two for cutting the ring grooves and one for cutting a small oil groove between the ring grooves. The holder just described is a very economical contrivance, and will be found useful for various purposes, as it can be made to hold one or more cutters up to its capacity, and can, of course, be made considerably wider than shown to accommodate more cutters; the extreme width permissible being dependent upon the rigidity necessary, or the class of work being done.

Other important styles of cutter holders are used for threading purposes; the advantage of these tools being accentuated by the convenience which is experienced when grinding blades of suitable section as compared with ordinary forged tools. A few types of these holders, together with lathe boring and knurling holders will be illustrated in the concluding section of this article in our May 3 issue.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

R. M. McCLEERY

THE county of Kildare, Ireland, forms part of the Province of Leinster, which is located in the East Midlands of the wonderful and historic Emerald Isle. History tells us that this name was derived from the constant and luxuriant vegetation, caused by the more or less continual rains that characterize the land of the Shamrock. Being within the range of the Gulf Stream influence the climate is comparatively mild the year round, the temperature in the month of January seldom falling below 40 degrees. In the town of Athy, not far from the greatest bog in the British Isles (the bog of Allen), the subject of our sketch was born, on July 21, 1883.

Robert Maxwell McCleery, chief draughtsman and designer with the John McDougall Caledonian Iron Works, Montreal, received his boyhood training at the Athy Model School and afterwards at the Athy Private School. At the age of fifteen and a half years, Bob decided to form one of the cogs in the wheels of engineering progress; his selection being the marine branch of the industry. His apprenticeship was divided between the shipbuilding firm of Harland & Wolff, Belfast, and the Central Engine Works; serving 3½ years with the former to marine engineering, and 1½ years with the latter to general engineering and ship repair work.

Realizing the necessity of improving his mental capacity, in the technical essentials pertaining to practical advancement, he found it advisable and also profitable to utilize his spare time in attending the evening classes of the Belfast Technical Institute. In order to broaden the scope of his efforts and at the same time acquire the wider range of experience, that can only be derived by travel, our "spoke", at the age of 22, came to Canada and settled in Montreal. His first position in the land of his adoption, was with the C.P.R., where he acquired a fair knowledge of locomotive construction and repair work. After about a year with this firm, he served about six months with the the Canadian Linotype Co. of Montreal. In 1906 our "Spoke" became identified with the John McDougall, Caledonian Iron Works; his primary position being that of general draughtsman. Promotion followed his close attention to details, and he has advanced from his initial position to that of Works Inspector, and thence to

ROBERT MAXWELL McCLEERY.

his present position of Estimator and Chief Draughtsman.

Mr. McCleery is a member of Crescent St. Presbyterian Church, Montreal, his other affiliations being membership in the St. Andrews lodge of the A. F. and A. M., and also of the Montreal Chapter of the Royal Arch Masons. As a distraction from mechanical worries, Bob spends many of his recreation hours in his favorite hobby of photography, he being what you might term a professional amateur in this interesting and instructive art. At present our "Spoke" is not married, but the early future may see a change in this connection.

Few engineering firms in Canada have been permitted to disclaim a part in the development of the munitions industry, and to a great extent, most mechanical men of the country have become more or less familiar with the actual production of one or more types of shell through personal supervision or in the layout of plants or their equipment. Being one of the first to place their plant at the disposal of the Shell Committee, there fell to the executive of the John McDougall Co., the duty of designing special equipment for the manufacture of 4.5 inch high explosive shell, and it is to the ingenuity and resources of our "Spoke" that much of the resultant success was eventually attained. Bob was probably one of the first, if not the first, to advocate and adopt the use of the cast iron chilled die for closing the nose of the shells. When first suggested, this method was ridiculed by many, but our "Spoke" persisted in designing his ideal die, and calculations proved that his surmises were not only satisfactory, but even surpassed his own expectations, the first die used suceeding in nosing nearly 3000 shells before having to be replaced. The cast iron chilled die is now quite extensively used by many shell makers.

Previous to the munitions activity, Mac. was actively and constantly engaged in designing and installing pumping equipment, gas engines and other special engineering work. Since the opening of the war he has personally supervised the construction of patterns and details, together with the manufacture and erection of certain large special wire machines used in the paper making industry. The original of these machines was of German make, but the war prevented the entrance of additional machines, with the result that the John McDougall Co. secured the right to build them, and those already completed are all in successful operation. During the past year our "Spoke" has assisted in the design of two triple expansion engines for a large Montreal shipbuilding firm. The estimating, construction of the patterns, and the casting of the parts were personally directed by him, and it might be here mentioned that the low pressure cylinders of these engines were the largest of their kind ever made in Canada.

"From general observation, regarding the study followed by young mechanics" says Bob "I have noticed that the numerous trade papers (particularly those treating of technical subjects), which come to this office are read with great interest, and in fact I find that in many of them, the different advertisements are intensely interesting and are a great help to me in my own work, enabling my keeping in touch with the various machines, etc., which are continually being placed on the market, more particularly since the shell industry has developed to such immense proportions."

Worm Gear Design Features and Worm Gear Mounting Detail*

By F. W. Lanchester

Progress that may almost be classed as extraordinary in worm gear design and arrangement is largely due to the research expended and inventive genius displayed by interests responsible for the now front rank prominence of automobile engineering.

EFFICIENCY FACTORS

It has been shown that, in worm gears of different types, the efficiency depends upon two factors, the pitch angle of the teeth and a constant—the coefficient of friction. In the work done with the author's dynamometer it has been made abundantly evident that the constant, the coefficient of friction, has a different value in different cases; it is liable to slight variation in almost every different pair of gears tested, but the variation only becomes marked when the type of gear as determined by the system of cutting differs, as for example, in the case of gear of the Lancaster or Hindley type when compared with gear of the ordinary parallel types. Now the reason for these variations has never been thoroughly investigated, and may have appeared to be somewhat obscure; the author has, however, expressed views on the subject from time to time. Briefly stated, the author's suggestion has been that the value of the coefficient is affected by the degree of proximate contact of the teeth and the consequent variation in the thickness of the oil film over the region by which the tooth load is borne—the thicker the oil film the lower will be the coefficient of friction. Although this view has been advanced with a more than plausible show of reason, there has hitherto been no actual demonstration offered in proof, and it can scarcely be said to have obtained universal acceptance.

Tooth Curvature at Engagement Surfaces

It would be possible in the case of the parallel gear to determine as a matter of pure geometry the extent of the clearances and the radii of curvature of the surfaces in contact at different point on the worm and wheel teeth where in engagement, and, in fact, in some degree this has already been done. It is conceivably possible that the same method might be used in the case of the Lanchester gear, but it would be extremely tedious and difficult, and at the best somewhat uncertain. From the photographs so obtained it has been found possible to prepare drawings showing the curvature at the engagement surfaces along the path of motion—that is to say, more or less nearly normal to the plane of the photographic section.

The initial problem of cutting and preparing the worm gear sections has presented certain difficulties of a minor character. In the first place, means had to be taken to ensure that the gears were fixed in their relatively correct running positions, not only before the dissecting of the gear, but as concerning the resulting portions or slices; the worm and wheel had to be so secured that they would be in no risk of losing their relative positions during subsequent handling. For this purpose the gears were mounted in a jig at the correct centres, and in proper engagement, and the whole of the gear teeth in the region of engagement were thoroughly grouted with solder. The next process was to cut away the portion of the gears in engagement, and then to slice these

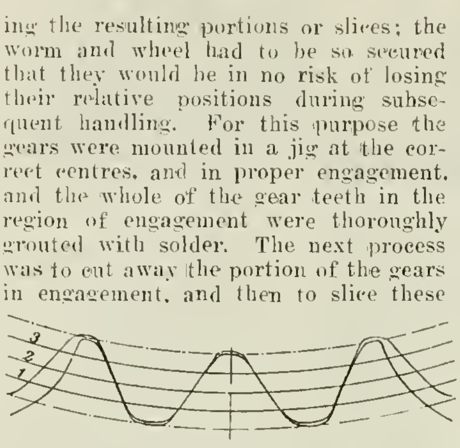


FIG. 6a.

up in a milling machine into sections of uniform thickness. In order to avoid unnecessary sectioning, both faces of each slice were photographed as representing sections, and the thickness of the slice (⅛ in.) was made the same as the thickness of the saw used in the cutting operation. In order that the photographs should read correctly, that is to say, so that they should be readily intelligible, the alternate numbers were reversed photographically, so that instead of the views being from alternately in front and behind the gear wheel, as is actually the case in examining the sections themselves, the photographs represent a series of sections one behind the other, all viewed in one direction.

There was some little difficulty experienced in obtaining a satisfactory process of etching in order to display the difference between the worm and wheel and the solder matrix. An attempt was made to use zinc in place of solder, and then to act on the polished surface with sulphuretted hydrogen or sulphide of ammonia. It was hoped by this means to bring out the zinc as a white ground on which the darker copper and iron sulphide would appear black in contrast. It was, however, found too troublesome,

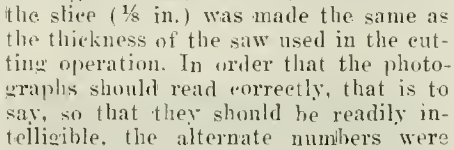

FIG. 6b.

if not impossible, to get the zinc to run properly and uniformly between the two surfaces. Several other methods of etching and polishing were tried.

Ultimately the method used was to etch the surfaces with stannous chloride, $SnCl_2$; under this treatment the worm and wheel appeared white on a dark background. The point of view of the photographs, however, does not give as clear an impression of the form or of the contiguity of the contact surfaces as might be wished; in order more fully to realize the type of the contact as defined by the difference in the radius of curvature of the two surfaces in their direction of relative motion, a development is required, in the case of the Lanchester the surface being one of double curvature. Any such development is of necessity a matter of convention—a convention involving some degree of distortion.

Determining the Tooth Sections

In the present case the construction adopted has been to take a number of concentric sections, three in all, one on the centre of the tooth height or pitch line, one at one-quarter, and one at three-quarters of the tooth height respectively; the reconstruction has been made in Fig. 7a, representing the Lanchester gear, and Fig. 7b, representing the parallel type. Since it is not the absolute curvature of the surfaces which is important, but rather the difference of curvature, and in order to avoid complicated draughtsmanship, the worm tooth faces have, as a matter of construction, been represented by straight lines, and the whole of the curvature has been assigned to the worm wheel tooth. Thus the tooth sections shown in Figs. 7a and 7b represent correctly the interspace between the teeth in engagement at various points, and so define the degree of proximate contact between the teeth, but the curvature of the worm and wheel tooth faces respectively must not be taken as individually represented.

Referring to Figs. 6a and 6b, which are the middle sections respectively of the Lanchester and the D.B.S. gear, it will be noted that whereas the surfaces represented by their development in Figs. 7a and 7b are surfaces of double curvature in the Lanchester gear, they are ordinary cylindrical surfaces in the case of the parallel worm; clearly, it is necessary to adapt the geometry to the variation of type. Thus, whereas in the Lanchester, as before stated, the development, Fig. 7a, must be regarded as to some extent a convention, in the case of the D.B.S. worm it is a true development of a right cylinder, and the assumption of the uniform and parallel worm teeth is strictly accurate. In Figs. 6a and 6b, the three surfaces of section at ¼, ½ and ¾ of the tooth height are numbered respectively 1, 2 and 3 in both cases, and corresponding figures of reference are given in Figs. 7a and 7b.

In order that it may be quite clear that the difference—the very striking difference—between the character of the clearances in the Lanchester gear 7a and the D.B.S. 7b are in nowise due to the

*Part II. of a paper read before the Institution of Automobile Engineers, December, 1916.

surfaces of section, Fig. 7c has been prepared on the same basis as that of Fig. 7a. It is not only clear here that no exaggeration of clearances has resulted from the method of representation, but it is also clear that the surface of section must necessarily be chosen in harmony with the geometrical basis of design—thus, in Fig. 7c, the conventional worm teeth appear in places where they actually do not exist.

Now referring to Figs. 7a. b. c, it may be observed that we are not much nearer being able to define how much of the worm tooth actually takes the pressure reaction, but reading these figures in conjunction with the photographs already referred to, we are in a position to state that for a given size of gear (centres), the effective area called upon to support the load will be greater in one case than in another. With so marked a difference in the curvature of the surfaces between the two types, if there were not some corresponding difference in the test result it would certainly be extraordinary. Yet H. Kerr-Thomas, in criticizing my previous paper, said, referring to the efficiencies of the two types of gear, "moreover, if the subject be treated from a purely theoretical standpoint the two [efficiencies] are equal, and the actual experience of a large number of users who employ a parallel type of worm shows that by this system satisfactory results are daily obtainable." I take no exception to the latter part of this statement—there are degrees of satisfaction—but the suggestion that there is any theoretical sanction for asserting that two so utterly dissimilar types of gear must have equal efficiency is not one to which any reply other than a direct negation is needed.

Of the experimental fact that the Lanchester type of gear will carry more load, centres for centres, than any parallel type hitherto tested, I think there is no doubt whatever. In the results now published there is an adequate explanation of and reason for this experimental fact.

In planning the cutting up of the worm block into sections, consideration was given to the fact that it is desirable to have one of the sections in the plane of the worm axis (as in Figs. 6a and 6b); the plan adopted is shown diagrammatically in the right-hand section (3) of Fig. 7c. The alternative presented itself of either milling away the last section and having no terminal record of the tooth, or of leaving the last section double thickness—the latter was the course adopted. Thus, taking the original face preceding the first section as O, the total width being 1½ in., the middle section falls to 6, and what would have been the eleventh section is missing, the terminal face being so numbered.

In the actual cutting of the sections, the thickness of the slices and widths of spaces of the different sections was not found to be accurately the same. This was in part due to the fact that the 1-3-in. saw used was slightly greedy, and cut the gaps wider and the sections thinner than intended, and in part due to the slices having been further thinned by the process of polishing and etching; in the case of the first set to be dealt with (the Lanchester gear), in which two or three experimental polishings and etchings were tried before the results were satisfactory, this is especially true. In transferring the data to paper in the preparation of Figs. 7a, b, c due allowance has been made for these variations.

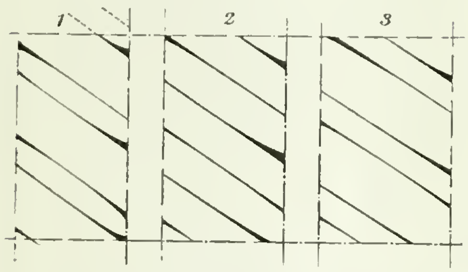

FIG. 7a.

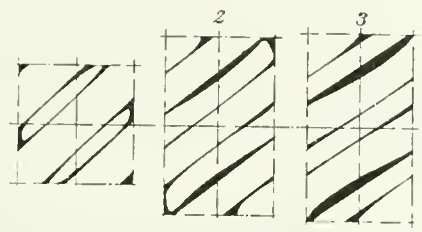

FIG. 7b.

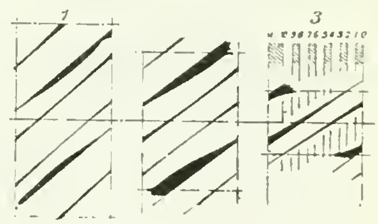

FIG. 7c.

Rubbing Surfaces Conditions

The conditions under which the rubbing surfaces of worm and wheel perform their duties are not sufficiently defined to allow an a priori estimate of the bearing capacity of the surfaces as based on their radius of curvature, or rather their difference of curvature. The curvature, however, must nevertheless remain some criterion, and, as an approximation to the truth, it would be reasonable to assign the bearing or load capacity on the basis that a certain proximity of contact is effective in the transmission of pressure as due to the oil film. The area of the two surfaces capable of transmitting pressure may be taken as an area over which the tooth surfaces come within some definite small distance one from the other. As a working basis we might take one of the surfaces as a plane, and the area in question will then be proportional, for spherical contact, to the radius of curvature. Where the contact is ellipsoidal and we know the radius of curvature in the major and of the minor axes, the area of proximate contact may be taken as proportional to the product of the square roots of the two.

The application of this method of assessment is not so easy. For example, in the Lanchester gear in Fig. 7a, and also in the actual photographs, there are surfaces which are optically in contact, and it would take more refined methods than those so far employed to enable the curvature difference to be assessed. In the D.B.S. gear, on the other hand, the curvature difference, both in Fig. 7b and in the photograph, is very considerable, but the variations are very considerable from place to place.

Worm Gear Mounting

It has frequently been urged, to some extent truly, that the Hindley or Lanchester worm gear requires greaser precautions in mounting than is the case with a gear of the parallel type. The point is that whereas in the Lanchester type the worm thrust has to be accurately located, in the parallel type, so long as the worm axis is correct as to position, the longitudinal location of the worm is of no importance. The matter may be carried a step further: worm gear of the parallel type in turn may be said require more careful mounting than common screw gear, in which both worm and wheel are of the ordinary screw-cut spiral form. Thus the argument that the Hindley or Lanchester gear is at a disadvantage, on account of the extra precautions required, as compared with parallel worm gear, may be quite as reasonably urged against worm gear of every kind in favour of ordinary screw gearing such as commonly used to drive the side shaft of a gas engine. Such arguments are clearly without weight if any adequate advantage can be shown to exist.

Location of Worm Thrust

In practice, the whole point of difference hinges on the correct location of the worm thrusts, since in every other respect any want or loss of alignment affects both types of gear equally. It may be doubted, as a matter of experience, whether the Hindley type of worm gear is actually at as great a disadvantage as its detractors would represent—the Lanchester gear, at last, has shown itself capable of working surprisingly well under the severe conditions which supervene when a worm thrust bearing fails. Admitting, however, that the durability of the gear, does definitely depend upon the permanence of alignment as determined by the thrust bearing, the problem resolves itself into the comparatively simple question of how, under manufacturing conditions, the initial accuracy of alignment can be secured; beyond this, the durability of the alignment resolves itself into a question of fixing the proportion and type of thrust bearing best employed, and of the general soundness of the mounting as a piece of practical engineering.

Early Type of Mounting

The earliest type of mounting employed in the application of worm gear to the original Lanchester car is shown in Figs. 8 and 9. Here it will be noted that the ball bearings are not of the modern type, the design dating back to a time when such bearings were not a standardised or a marketed commodity: two double bearings of the bicycle cup and cone type are arranged at opposite ends of the worm, the whole combination being symmetrical. The cups were made adjustable by housing them within an internally screwed sleeve

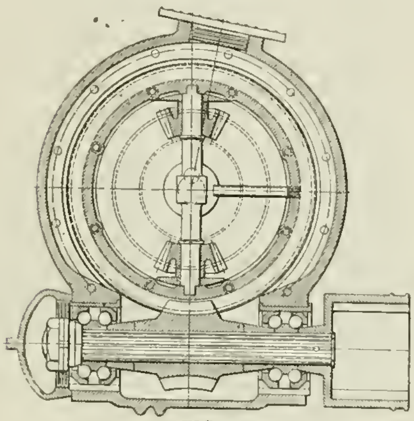

FIG. 8.

piece, and the adjustment was fixed by a key or cotter engaging with one of 24 notches cut in the periphery of each cup, Fig. 8a. The pitch of the thread was twelve per inch, so that the design gave a capacity of adjustment to within approximately 3½ one-thousandths of an inch, which was found to give satisfactory results in practice. Here we stumble against one of the misconceptions which are current with regard to the Hindley type of gear: it has often been represented that the accuracy of alignment of the worm requires to be true to within a thousandth of an inch of geometrical accuracy; from the success of the arrangement described, it is clear that no such degree of accuracy is essential.

It will be noted in the bearing in question that (as in the case of the old bicycle ball bearing) there is no separate function of cylinder bearing and thrust, and without doubt from a modern stand-

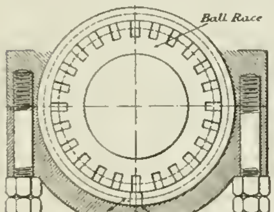

FIG. 8a.

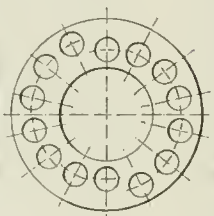

FIG. 10.

point the type of bearing shown in Figs. 8 and 8a would be considered lacking in durability. No trouble was experienced from expansion (due to temperature) as between the two thrust bearings, and it is fair to regard the casing, as indeed the whole of the parts, as

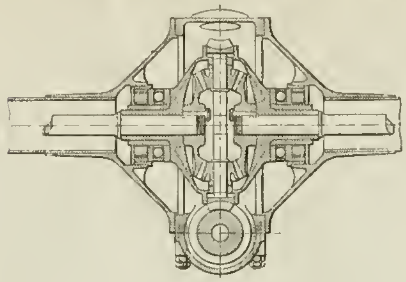

FIG. 9.

sufficiently elastic to take up any small temperature difference. It is possible that at times one thrust bearing is called upon to sustain more thrust and at other times less than its fellow, but there has been no actual evidence of this taking place.

The worm wheel bearings shown in Fig. 9 are roller bearings of the cheese-roller type without cage of any kind. These are in fact the bearings on which the balance gear-box is mounted, and the worm wheel itself forms the central section of the balance gear-box. The thrusts were of a specially designed type, and consisted of balls in a flat cage between two perfectly flat ground and hardened thrust washers, the balls being arranged in a spiral manner Fig. 10. The object of this arrangement, i.e., the spiral distribution of the balls, is that each ball may bear on a different part of the flattened surface, so distributing the wear; a

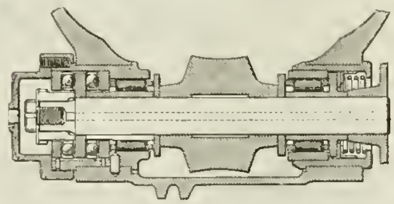

FIG. 11.

further advantage is, that if the balls vary amongst themselves as to diameter, as is commonly the case, each ball will form its own race and will soon be taking its due proportion of the load—the markings on the thrust races frequently gave evidence of this action. The degree of inaccuracy amongst balls of nominally the same diameter is commonly less than one ten-thousandth of an inch. This form of bearing was in every way successful and satisfactory; that it has since been dropped is due to the fact that excellent thrust bearings have now been placed on the market by specialised manufacturers.

Modern Worm Mounting

In the modern worm mounting the type of bearing given in Fig. 8 has been long since abandoned, and to-day it is the invariable practice to separate the functions of radial load and thrust and provide for each by a bearing specially designed for the purpose. Thus, in Figs. 11, 11a, 12, and 15, a roller bearing is employed independent of the thrust, and in Fig. 16 and those which follow it will be seen that the radial bearing commonly used is the symmetrical type of ball bearing as now to be obtained from several firms, such as the Hogman, Skefko, Duplex, etc., and that thrust is independently carried. In some cases the radial bearing takes the form of a roller bearing, as in the worm wheel bearings already given in Fig. 9.

It is worthy of note that in the modern mountings, the thrust bearing, a double thrust, is almost invariably fitted at one end. Objection has been taken to this arrangement on the ground that any inequality of expansion between the worm shaft and the casing will throw the worm out of centre; in other words, the objection is based on the fact that the arrangement is unsym-

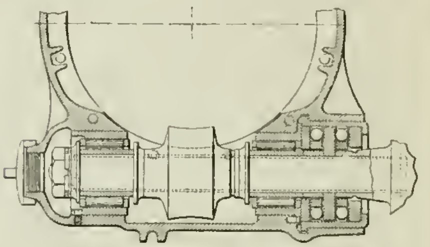

FIG. 11a.

metrical. There are two answers to this. Firstly, the temperature difference is a mere "bagatelle;" thus the whole range of temperatures between the hottest and coolest parts of the gear-box is included between an atmospheric temperature, say 20 deg. C., and an upper extreme of about 100 deg. C.; speaking generally, the difference between one part and another does not exceed 40 deg. C. or 50 deg. C. At worst, calculation gives the relative displacement of worm centre line and the wheel centre line due to the cause stated as not exceeding two or three thousandths of an inch. In practice it is doubtful whether it is ever as great as this: in any case it has not been found to be detrimental. Secondly, if, as is the only alternative, the thrust and counterthrust be arranged at opposite ends of the worm shaft, there will be a much bigger expansion difference to take up between thrust and counterthrust, probably twice as much as now between worm and thrust bearing. This expansion might have a detrimental effect on the thrust bearings and ultimately lead to their disintegration. The failure of a thrust bearing must be regarded as perhaps

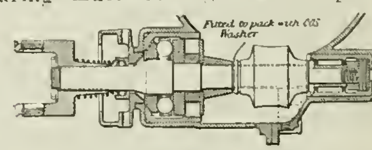

FIG. 12.

the worst "accident" which can happen to a worm gear.

There follow in detail a few of the later and more successful types of worm mounting, and some of those which are historically the more important. The first series which will be taken will be in continuation of Figs. 8, 11, and 11a, showing the historical development of worm mounting in the practice of the Lanchester Company. It will be noted on comparison of the figures given that there are certain features of the Lanchester mounting which have survived from the earliest designs, notably the splined shaft on which the worm assemblage is mounted, also the method of building in the worm wheel as part of the balance gear-box, and in providing for the housing in the worm wheel casting itself of the cross pin or pins on which the balance gear bevels are mounted.

In this arrangement, which is common to the whole of the series, it will be seen that the drive from the bevel wheel is taken directly on to the balance pinions, and the covers of the balance gear-box are not used to convey torque but only the thrust and other forces by which the wheel is held in alignment. It will be noted that the

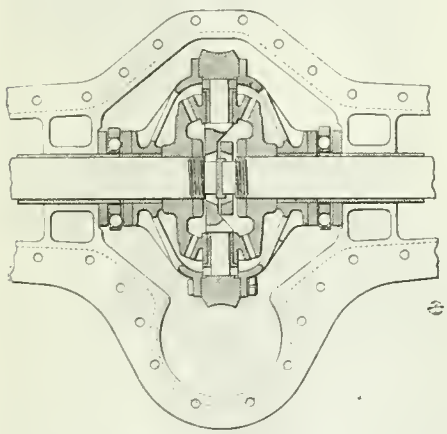

FIG. 13.

thrust bearings serving the balance gear-box take not only the worm thrusts, but also the axle thrusts. There is a bronze pad fitted between the axle ends by which the thrust is conveyed from one axle to the other and thence to the thrust bearing. Another incidental feature which may be noted is the fact that there are four balance pinions in the differential gear-box, each pair mounted on a transverse pin; the figures show clearly the means taken in the design of these cross pins to permit them to clear each other and to clear the axle ends and thrust pad. So far as the worm gear mounting is concerned, these are mere incidents, but the method by which the drive is conveyed from the worm wheel to the balance pinions is a matter which is essentially of interest.

Coming back now to the more directly important points, we may, with reference to Fig. 11, call attention to the first advance in worm mounting after the type shown in Fig. 8. In this we see that roller bearings brought well up to the neck of the worm have been substituted for the bicycle type of bearing in the previous figure, and a double ball thrust between flat parallel races has been applied at the tail end of the worm shaft. This design, again, was before the period in which ball or roller bearings could be purchased from specialised makers, and the bearings were made in

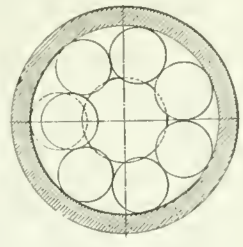

FIG. 14.

every detail at the Lanchester Co. Works. It will be seen that the thrust bearing in this design is very compact, but from the modern point of view and with present-day loads and speeds it would not be considered adequate. Owing to the incline of the worm shaft and the importance of ground clearance, the tail position is at a disadvantage compared with the driving end of the worm shaft in the matter of permissible diameter, hence, when we pass to a later design, Fig. 11a, in which the bearings (both cylinder and thrust) are far more robust, the thrust is fitted at the neck or forward end.

In Fig. 12 (early 20 h.p.) we find that the ball thrust bearing has again been arranged at the forward end of the worm, and in this design an innovation was tried experimentally to do away with the ball counterthrust and employ a series of thrust washers, the efficiency clearly being a matter of no importance when the brake is being employed. A notable feature in this design is the very large diameter of the thrust balls. Fig. 13 gives the corresponding section through the worm wheel axis. Here we see the spiral type of thrust bearing with flat races still holding its own.

Cheese Type Roller Bearing

A feature which is worthy of mention in many of these early mountings is the employment of the "cheese" type of roller bearing, that is to say, a type in which the length and diameters of the rollers are about equal. This is a type of bearing which the author developed in the experimental period of car building, and which was used in the gold medal phaeton built in 1897-8. The employment of this type of bearing was extended considerably in the 10-12 de-

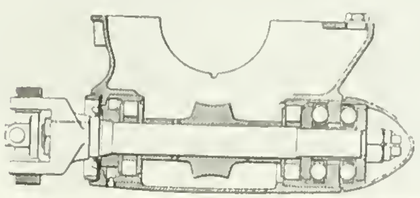

FIG. 15.

sign in 1900, where it was used throughout the rear axle and parts of the countershaft. It is only within the last few years that bearings of this pattern have been taken up and introduced by the Hoffmann Co. and others. There is a difference in practice, inasmuch as the bearings marketed at the present day appear to be all fitted with cages, whereas in the author's experience a cage is absolutely unnecessary in bearings of the "cheese" roller type. In any case the guiding of the rollers is done from the ends, and this is really the definite distinction between the ordinary roller bearing and that of the "cheese" type, in the former the roller being guided from its cylindrical surfaces, the cage being a necessity. Generally speaking, it has been the author's practice so to design the bearing that the rollers, once in position, could not fall out; thus in the axle bearings shown in Fig. 9 the the diameters of rollers and races were such that the axle or central race could be removed and the rollers could not be displaced. The clearance was so small that the rollers would lock before they could come free, as illustrated diagrammatically in Fig. 14.

A still later type of mounting is given in Fig. 15. On the worm bearings we

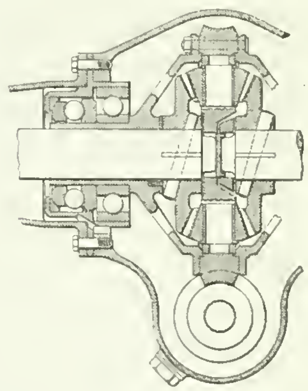

FIG. 16.

again see the cheese roller bearing of the cageless type employed, and a double thrust bearing on the tail end of the shaft. The whole outline of the worm housing, however, has been made very clean and smooth externally. The corresponding axle mounting is given in Fig. 16. Here it may be seen that on the axle bearing the ball has to some extent replaced the roller.

It may almost appear, in looking at these changes, that in some cases, in which the change goes from one arrangement to another, and then back again at a later date, there is certain evidence of infirmity of purpose. As a matter of fact changes are frequently due to conditions which are temporary, and often two designs are so nearly equal in merit that whether one or the other be adopted is purely a matter of convenience. A great deal must depend upon whether the designer has a completely free hand or whether he is required to make use of standard components. It will be noted that amongst the various changes the practice of the Lanchester Co. has always been to place the worm shaft below the axle.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

BOSS LOCK NUT SAFETY FACTOR

SAFETY is one of the outstanding features of present day engineering practice. The movement of "protection against accident" has become so general that it is a rare plant indeed that minimizes the importance of this essential factor. The application of the "safety first" principle has met with

SQUARE AND HEXAGON LOCK-NUTS

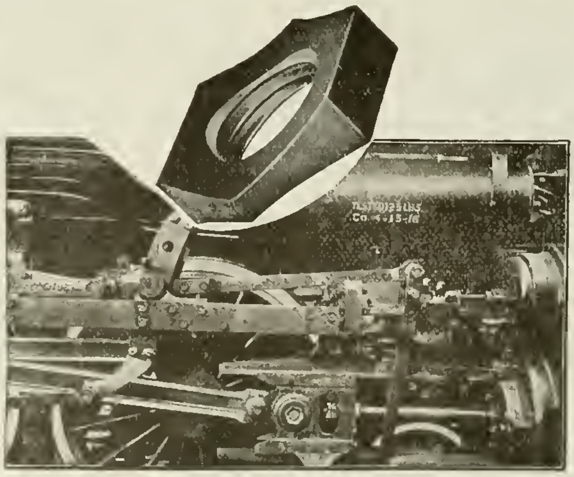
such universal approval that manufacturers of every description are rapidly recognizing the many advantages that result from its more extended operation.

Accidents to operators and destruction to machinery can be traced to many sources, but it is safe to say that a fair percentage may be caused, directly or indirectly, by the loss of a nut from some part of the plant equipment. Owing to the vast and varied uses to which bolts are put in the construction of every conceivable piece of mechanism, and the important part they play in the successful operation of machinery, it is essential that sufficient means be provided to prevent the displacement of a bolt from its fixed position. This feature of engineering practice is more pronounced where bolts and nuts are used to connect parts of machinery, or other construction, subjected to continual shock or vibration. Under these conditions, it is very necessary that ample consideration be given to the prevention of accidents, often caused by a nut being dislodged, with possible disarrangement of the machine parts, followed by accidents to the equipment or the operators.

It has been often said that "Prevention is better than cure," and this term is equally applicable to engineering as to "other forms of evil." To prevent a nut being displaced is, therefore, much better than to repair the damage after the accident has occurred. Many forms of jam or lock nuts have been designed and adapted to retain bolts in their initial position. The simplicity of the nut here illustrated is one of the chief features of its efficiency. The construction of this lock nut is designed with the threads tapped out to standard size, so that the nut can be placed on the bolt and spun up to the primary nut by means of the fingers, without the use of a wrench. It makes no difference which side is in contact with the adjacent nut, as either side may be used with the same effectiveness. These nuts, which are cut from a bar, have two parallel sides, the faces being concaved at right angles to the edges, forming a regular arch. When the nut has been spun down to the face of the primary nut, the two parallel edges of the lock nut come in contact with the face of the other, and by means of a wrench the lock nut is turned through an angle of from 90 to 180 degrees. The pressure thus exerted bends the lock nut, causing the threads therein to be distorted, consequently gripping the threads of the bolt very firmly, so that it is impossible for the nut to become loose.

Even should the bolt elongate under the strain and the primary nut become loose, the lock nut will remain in its original position, so that any slackness cannot exceed the elongation of the bolt, which is seldom, if ever, sufficient for the bolt to become loose. When the arch has been drawn downwards so that the threads register deeply and firmly into the valleys of the threads of the bolt, the lock is so positive that no movement will take place between the three members—the bolt, the primary nut and the Boss lock nut. If it is necessary to remove a bolt upon which these lock nuts have been used, the lock nut can only be removed by means of a wrench, and this acting throughout the entire length of the threaded portion. These nuts are being placed on the Canadian market by the Boss Lock Nut Co. of Canada, 263 St. James Street, Montreal.

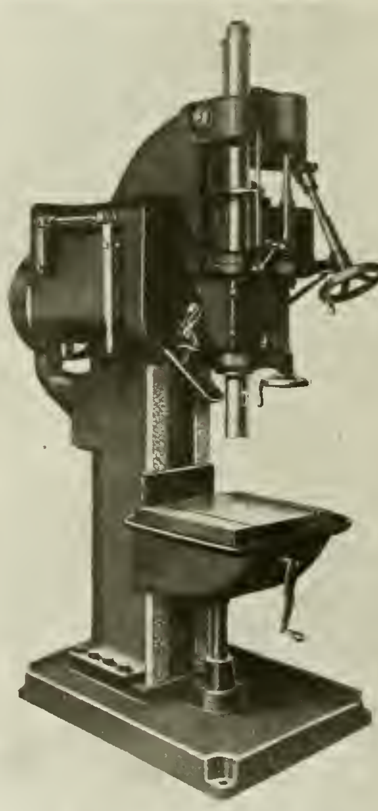
BOLT WITH LOCK-NUT IN POSITION.



VIEW SHOWING APPLICATION OF LOCK-NUT TO LOCOMOTIVE PARTS.

HEAVY DUTY PRECISION DRILLING MACHINE

THE machines shown in accompanying illustrations have been designed with a view to obtaining the highest efficiency



HEAVY DUTY PRECISION DRILLING MACHINE.

in performance, including every requirement from heavy-duty capacity to precision work of the greatest accuracy. Reference to the illustrations will show that the machines are almost similar as regards the column and mechanism, but different designs of base and table are provided for the particular class of work in view. Simplicity in construction and operation have been kept constantly in mind, resulting in very complete freedom from complicated levers and handles.

The machine shown in Fig. 1 has a heavy column of box construction bolted to a base of generous dimensions, the part of the base under the column being arranged to form a reservoir for the cutting compound which passes through a sieve into the reservoir. The work table is mounted on planed ways on the front of the column, these ways being carried up

HEAVY DUTY PRECISION DRILLING MACHINE.

high enough to allow of mounting special boring heads for multiple spindle drilling work. The table itself is plain box section, strongly ribbed, and has channels around edge to carry off compound. It is secured to the column by heavy straps; has liberal bearing and length on column, and is raised and lowered by telescopic jack screws.

Constant speed drive, either belt or motor, is a feature of the design, the variation of spindle speeds being obtained by a speed box contained in the interior of the column. The speed box contains nine hardened change gears and four semi-steel wide-faced gears operated by the controlling clutch. Gear changes are made by a roll-in gear, and only two idle gears are in mesh when the machine is in operation. For single purpose work, the speed box can be replaced by a single speed drive or a three-step cone.

The spindle is provided with a sleeve carrying a large bevel gear which is driven by the bevel pinion of the speed box. The bevel gear is secured to the sleeve by two steel keys, which are so designed that the torque from the bevel gear is transmitted direct to the spindle on its largest diameter without causing stress on the sleeve. The lower end of the sleeve has a tapered bearing in the spindle head; its upper end is straight and is fitted with a tapered sleeve keyed in place, this arrangement allowing the sleeve to expand without tightening the bearings, while maintaining the spindle and sleeve in alignment. Both the spindle and sleeve are of forged crucible steel and accurately ground to fit each other and the sleeve bearings.

The bevel drive gears and worm feed gears are housed in the spindle head and run in grease, and the spindle sleeve double friction clutch starts and stops the machine, and a ball thrust bearing carries the thrust of the large drive bevel.

Semi-steel gears are fitted in the feed box, with slip key that moves into the particular pair of gears selected. The feed box is bronze bushed throughout and is provided with safety friction and automatic knock-off.

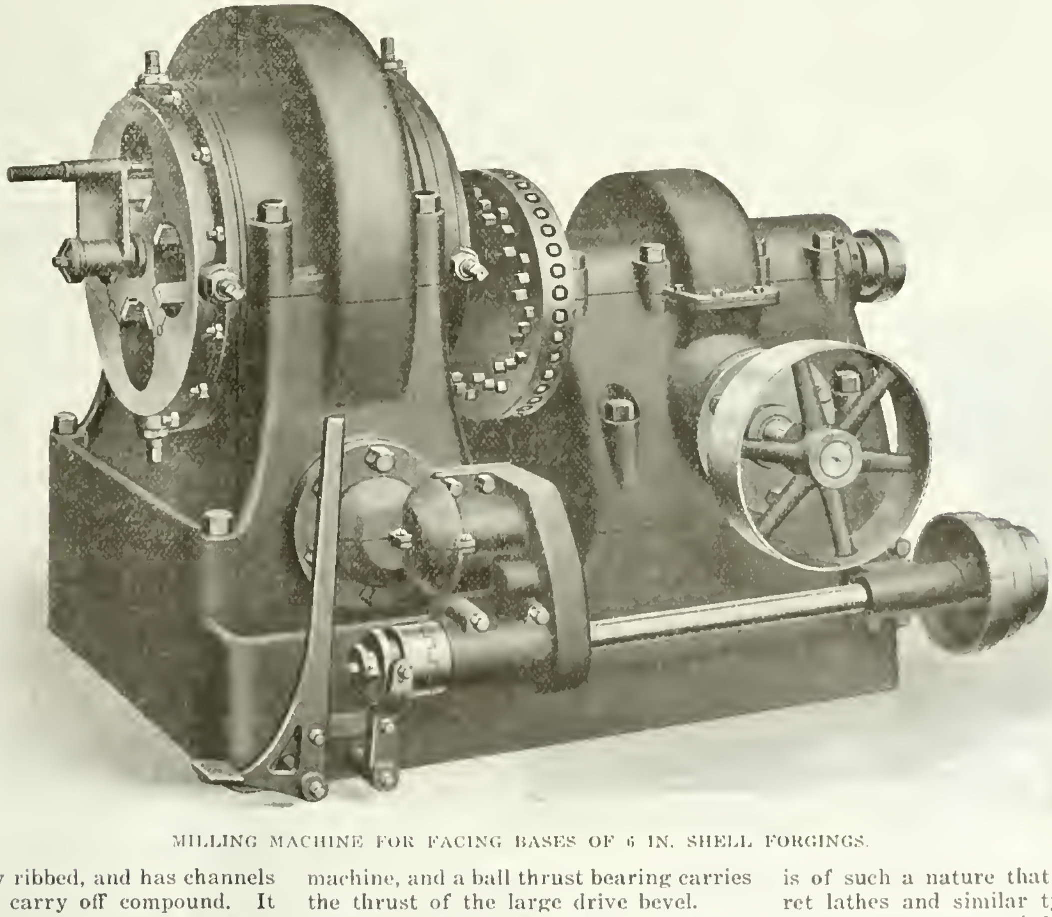
When constructed as in Fig. 2, the machine is known as a universal spacing machine, the arrangement having been developed to meet the requirements of jig boring and similar operations, and it is suitable for regular operations, on work where it is necessary to bore holes to close limits without the use of jigs. A specially designed adapter gauge, not shown, combined with use of set blocks enables holes to be spaced within .00001 in. A planed strip extends along the rear of the base and also of the platen resting thereon, both of which have three T-slots for securing in place. The auxiliary platen on top may be used either with the main platen or base as required and is located in position from the planed strip at rear, an adjustable stop secured in the T-slot providing a base point for sidewise location.

Leading dimensions applying to both machines are: spindle dia. 3½ in.; spindle traverse, 14 in.; 8 spindle speeds from 54 to 414 rev. per min.; 4 power feeds, .006 in. to .032 in.; capacity to drill, 3 in.

These machines are the product of the Medina Machine Co., Medina, O.

SHELL BASE FACING MACHINE

THE removal of surplus metal from shell forgings constitutes an operation which calls for considerable power, but is of such a nature that the use of turret lathes and similar types of tools is not always accompanied by the highest degree of efficiency or rate of output. These and kindred considerations prompted the development of the con-



MILLING MACHINE FOR FACING BASES OF 6 IN. SHELL FORGINGS.

tinuous shell base facing machine illustrated herewith, which, while classified as a single purpose tool, is adaptable to much other work where a large amount of stock is to be removed.

The design is featured by the use of a revolving cylinder or magazine having four axial holes or pockets in which the shell forgings are placed. The shell pockets are fitted with hardened tool steel inserts for holding the shells, which are securely clamped at each end by hardened binder screw working in removable steel nuts. The magazine is rotated in its bearings by means of a worm gear which surrounds it, and is driven by a steel worm running in oil.

The steel cutter head is 19½ in. dia., and carries three rows of high-speed tools, and is mounted on a high carbon steel spindle driven by a 16-in. worm gear. Each of the spindle bearings is 5½ in. dia x 10 in. long, ground to size, and running in phosphor bronze bushings. The worm gear is of bronze and meshes with a steel worm, which, like the magazine worm runs in an oil bath.

A three-step cone, with 2-in. belt, operates the magazine feed gear, an alternative being an all gear drive and gear box, which gives four changes of feed. All-feed gears are of steel, with bronze bushed bearings, and a hand or foot operated clutch is provided on the feed shaft for controlling the rotation of the magazine. The base of the machine forms an oil tank, a geared pump and pipe connections being supplied.

This machine is designed to handle 6-in. shells, and is built by the Rollins Engine Co., Nashua, N.H., and occupies a floor space of 5 ft. 9 in. x 4 ft. 7 in.

FRICTION HEADSTOCK LATHE

THE lathe shown in the accompanying engraving is especially adapted for the rapid production of small machine parts, and, with this end in view, has been provided with draw-in mechanism and friction-driven headstock, the combined operation of which is accomplished by a pedal. A spring underneath the sleeve draws the collet back into the spindle and closes it on the work.

This sleeve is spanned by a forked lever, which, when operated by the pedal, opens the collet and stops the spindle instantly, so that the work may be adjusted by the operator whose hands are both free for handling material or tools.

The spindle runs in self-oiling bronze bearings, and has a hardened bushing fitted in the nose to prevent wear by the collet. It is also threaded to receive chuck or face plate.

This machine is a recent product of the J. G. Blount Co., Everett, Mass., and can use collets up to ⅝ in. The headstock is also arranged for mounting on bench.

LATHE WITH PEDAL-OPERATED FRICTION HEADSTOCK AND DRAW-IN COLLET.

OUR PRESENT PROSPERITY DUE TO STEEL

ROBERT HOBSON, president of the Steel Company of Canada, stated at the annual meeting which was held in the Royal Connaught Hotel, Hamilton, on April 19, that the steel business would continue to be large while the war lasted, but on peace being declared there would be a period of adjustment. The old board of directors was re-elected and the annual financial statement, which had been issued earlier to the shareholders, was received and adopted, in this statement it was shown that the net profits for the year after deducting charges for repairs, maintenance and improvements and providing for war taxes for the year 1915 and 1916 were $5,021,391.53.

The period of adjustment after the war, said Mr. Hobson, will mean that financial arrangements in Europe will have to be lined up and the credit of foreign purchasers, other than the Government, will have to be carefully considered. He said that the wisdom of establishing steel plants in Canada had been fully proven during the past two and a half years. Without these plants, Canada could not have provided the material for the vast quantities of munitions which had been turned out since the war started. Such activities, he said, had been largely instrumental in putting Canada in her present favorable financial position. Reference was made to the fact that the company had provided a fund for nearly one million dollars to meet after war conditions.

FELLOWSHIPS FOR RESEARCH WORK

TWENTY studentships and five fellowships in Canadian Universities will be established by the Honorary Advisory Council for Scientific and Industrial Research. The studenships are open to both men and women, and are each of the value of $600 for the first year and $750 for the second year. The candidates for studentships must be British subjects, resident in Canada or graduates of Canadian Universities, and must be between the ages of twenty and thirty-two years. Applications for studentship must be made to the Advisory Council.

The research fellowships are of the value of $1,000 for the first year and of $1,200 for the second year. Fellowships will be awarded those who either through previous tenure of a studentship or otherwise have shown a high capacity for research on some problem the extension of which is of importance to the national industries of Canada.

Hospital Humor—.At a certain hospital, which shall be nameless, there is a doctor so dark in complexion as to be generally considered a half-caste, but it is impossible to offend him worse than by an allusion to the fact.

This gentleman, though very clever, is somewhat unsympathetic.

Recently a number of wounded soldiers were received into the above-mentioned institution, and amongst them was a Birmingham man who had borne a great amount of suffering very patiently, but became rather irritable as he began to recover.

One day the doctor surprised this particular patient by inquiring if he was breast-fed or bottle-fed as a child.

The man replied that he thought he had been breast-fed.

"H'm I thought so," remarked the doctor, sarcastically. "I have frequently noticed that people who were breast-fed as children make ten times more fuss in illness than those who were brought up on the bottle."

"Which were you brought up on?" inquired the soldier, after a short pause.

"Bottle," replied the doctor. shortly.

"Ah! I thought so," replied the Tommy contemptuously regarding the dusky skin of the other, "and it must have been a bally ink-bottle. too!"

MACHINE SHOPS AND TRACTORS

PRESENT conditions in regard to agriculture and its resultant effects on the world's food supply have caused more than a passing interest to be taken in the matter of power cultivation. Numerous concerns, particularly in the States, are reported to be entering the tractor industry daily, and production estimates of four and five figures are spoken of with the same glibness that was shown when the "caterpillar" principle was brought so prominently before the public by the success of the tanks.

Much public discussion will not result in any mechanical idea being adopted on a wide scale simply because it has achieved marked success under peculiar circumstances, and the fact that caterpillar tractors have been regularly produced for something like twenty years, without any signs of recognition by agricultural experts and publicity mongers, would seem to indicate a lack of appreciation and consequent inability to pronounce on the merits of such machines. Caterpillar tractors obviously have special applications and more or less limited markets and should not be confused with what might be termed the "iron horse" which the average farmer requires.

Out of the numerous designs which have appeared in recent years a type or types will survive, and a sympathetic study of average farm requirements by technical experts should do much to hasten a finality of design. The use of kerosene and low-grade fuels is quite as important as whether there should be three wheels or four wheels, but if a tractor is to displace horses in the field it should also displace them in straight road haulage. There are, of course, some circumstances where a horse may not altogether be dispensed with, but the displacing of the buggy by the automobile really removes the last toe-hold of the horse.

Excepting the motor, which can generally be obtained to advantage from specialized producers, a practicable and efficient tractor design does not offer any constructional problems which cannot be successfully handled by many firms in the Dominion. Intricacy of design and complexity of construction will not avail in the tractor of to-day as they did in the early automobile, and the simplification of tractor design to the point mentioned is well within the ability of any competent machine designer.

The question of marketing would offer new problems to certain producers, but a firm which adopted aggressive demonstration methods with the same energy and resource as are frequently displayed in marketing machine shop equipment, would not lack work for years to come, provided it had the goods.

COAL WILL CONTINUE SCARCE AND DEAR

WITH the advent of spring weather and the near approach of the good old summer time, there is already evident a disposition to forget our past winter troubles and inconveniences, due to lack of coal for manufacturing and domestic services in both quantity and quality, the latter probably more aggravated than the former. Even now, when to all appearances, we are still well removed from the firing of the last shot in this apparently cruel war, a powerful public opinion—essentially scientific and moral perhaps, deems the conflict to have been worth while and altogether necessary to our future well being. The reason is not far to seek, and need not be looked for en masse; it being as a matter of fact a more or less individually determined conclusion arising from personal experience. We have come to appreciate things more in keeping with their proper value and in so doing to extract from them the commensurate return. It is hard, however, to get away altogether from the idea that the war in much of its detail has been other than tyrannical, and so far as we on this North American continent are concerned, the coal situation during the past winter on many occasions by its maintaining a generally threatening aspect and seriously affecting industrial enterprise and domestic comfort, contributes its quota to such a condition of mind. From well authenticated sources, our information is that not only may little price relief be expected—if any, but much below normal supplies of coal are also likely to be received. The 1917 season of navigation on our lakes and rivers is going to be less effective in accumulating coal supplies than ever before, due not only to the shortage of "bottoms," but to such other causes as the shortage of labor at the mines, and the reduction in railroad rolling stock available for such service. The foregoing applies to coal receipts from within our own borders, as well as those from beyond.

Already not a few enterprising concerns are investigating the possibilities and propriety of installing oil fuel equipments in connection with their present boiler layouts, whether high or low pressure be their service, and there is little doubt that before the summer season is well through, definite progress in this particular direction will have been made in many cases. It seems in order to again impress our readers—executive and operative, with the remote prospect of lower coal prices during the summer season than those now prevailing, and to advise that not only will they be higher during next winter than last, but the higher levels will be reached much earlier than usual. Something like $5 per ton for bituminous coal at pit mouth, in Pennsylvania is now quoted, and anticipations are that $7 per ton at pit mouth will be the price ruling before the summer is over. Such coal in pre-war days ranged from $1.50 to $2 per ton at pit mouth.

As regards manufacturing enterprise, high fuel cost will mean high power production cost, making it incumbent that, while the latter cannot wholly be avoided, steps be taken to not only conserve it, when generated, to the fullest extent possible, but ensure that, in its transmission and application features, avoidable losses, such as friction, leakage and kindred forms of waste be taken care of. Installation of the most modern types of power generation equipment will also be more than ever essential in the coming time.

The General Market Condition and Tendency

POLITICAL developments in the United States continue to affect the situation in Canada, principally with regard to prices of iron, steel and metals. Uncertainty as to what the American Government may do in the way of regulating prices is the cause of the unsettled outlook, meantime prices of steel products continue to advance, due entirely to the question of supply and demand. Iron and steel bars and small shapes have advanced. Iron bars are now 4.75c, steel bars 5c, and shapes 5.25c. Higher prices on a number of other steel products are looked for in the near future, among which may be included rivets, nuts and bolts, plates and tubes. The pig-iron situation is unchanged with prices entirely nominal. The shortage of pig-iron is becoming daily more acute, as furnaces are in a sold-up condition and stocks are very low. The embargo on steel turnings and borings is again in force with the result that prices have been forced down, due to the restricted market and accumulation of supplies. Prices of copper and brass scrap have declined, but heavy melting and other steel scraps continue firm and in good demand. Non-ferrous metals, with the exception of lead are weaker in sympathy with the New York market. There is a lack of interest in the market on the part of consumers who are waiting developments. There is a feeling that the American Government may fix prices on its requirements, and thus tend to weaken the market and cause a decline in values. Copper has declined 1c per pound. The machine tool market is a little more active, with indications of a return to normal business.

Montreal, Que., April 23, 1917.—The political outlook still dominates the situation and an air of uncertainty pervades the general market. The industrial interests are still undecided as to the effect the changed conditions will have upon trade relations between this country and America, and the attitude at present is one of waiting, to see what developments will follow the plans of the United States Government when their war policy is definitely announced. The visit of the Allied representatives to the United States may have considerable bearing on the early future of both relationship and industrial activities. At present a certain lull prevails following the rumor that is current regarding the intention of the Imperial authorities to discontinue the manufacture of large shells here in Canada.

Pig Iron

The Canadian pig iron market is practically unchanged, there being no market, so to speak, as producers are virtually out of the running. What iron is being produced here is entirely absorbed by the producers themselves. The American situation has again been subjected to a general advance, approximating $1 per ton, more noticeably on foundry iron. The composite pig iron market shows an advance of 40 cents per ton.

Steel

The general situation is little changed from that of a week ago, but the constant rise to still higher price levels reflects the abnormal conditions that prevail in the steel branch. That various grades of steel and other commodities will go still higher is the unquestionable opinion of the trade, as these are not expected to suffer from any action of the producers in supplying the requirements of the American Government. While no apparent tendency has yet been shown by consumers to turn away from the ever advancing trend of price quotations, an undertone of perplexity is undoubtedly evident on the part of buyers as to where the tide is going to stop. The pressure on the mills continues to be as great as ever in the past, and it would only be by a sudden cessation of hostilities that the present strength of the steel market could be affected. Even this might not have an immediate effect upon existing conditions, as the majority of orders placed for this year and well into 1918 have been accepted on a non-cancellation basis. It is not expected that the needs of the U. S. Government will materially affect the export of supplies to the allied countries. The possibility of a reduction in the quantity of heavy shells required from this side of the Atlantic may relieve the situation in steel billets; as a matter of fact, some producers in the States are looking forward to contracted tonnage being turned over to other forms of steel, as original contracts had a clause inserted to the effect that this option would be permitted at any time during the period of the contract. With the price of forging billets now at the century mark, a movement of this kind might prevent this class of steel from reaching a higher level. The Pittsburgh quotation on iron and steel bars has been advanced $5 per ton, the price asked being now 3¾c per lb. The demand for plates is as insistent as ever; the requirements for cars have fallen off, but this is more than balanced by the ever increasing inquiry for ship plates, the activity in this direction marking developments in shipbuilding that tend to dispel any possibility that prices on this class of steel will experience any sudden collapse for many months to come. The increasing cost of raw materials and also the heavier demand for all kinds of sheets has again resulted in a general advance on these products; the most recent quotation from the Pittsburgh mills indicate an advance of approximately $20 per ton on tin mill black and black sheets, this week's quotation being 7c per lb. Blue annealed sheets on an advance of 1¼c are now quoted at 6¾c. While these sharp advances have somewhat discouraged buyers, sales show relatively little falling off. Galvanized sheets are now quoted at 9c Pittsburgh, an advance on the week of $30 per ton. The action of the American Government in requesting a larger supply of tinplate from the sheet mills, is largely responsible for this sudden advance in the price of sheets. While the demand for railroad spikes is not exceedingly heavy, the higher cost of semi-finished steel has necessitated an advance in price, this being about $4 per ton. The expected rise in wire products has become effective by some of the large mills, and will likely become general within a short time. The recent advance is $6 per ton, the Pittsburgh prices being $3.45 for plain wire, $4.15 for galvanized wire, $3.50 for wire nails, and $3.65 for painted barb wire. Three points have been taken from the discount on wire fencing, the present discount being 48 per cent. The supply of wire rods is gradually decreasing owing to the fact that producing mills are using more and more of their own product for the making of wire and wire nails. This will eventually mean higher prices on these products. Inquiry for wrought iron pipe and boiler tubes continues very heavy, and a higher market is not unlikely. A pleasing condition arising out of the better transportation facilities is the increased shipments of coke from the ovens to the blast furnaces, resulting in a lessening of the demand and an easier market. New York reports a decline of 50c per ton on both furnace and foundry, the respective prices being $8 and $10.50 per ton. The local situation is much the same, but with a much stronger undertone. Dealers anticipate higher prices within a short time if present conditions continue, but the general market is unchanged from that of a week ago. Securing of supplies is as difficult as ever, despite the fact that railroad transportation is much better, the dominating feature being the inability to obtain material from the mills.

Metals

No unexpected feature has developed in the metal market; with the exception of tin and lead, the general situation is showing weakness. Until the working policy of the United States has been announced it is the general opinion that a more or less unsettled condition will be apparent. This factor of the present market tends to uneasiness among dealers and consumers, resulting in an inactive demand for the various metals. Future inquiry for copper is light, and, owing to the fact that consumers are fairly well covered for first half requirements, the present market is quiet. Tin is maintained in a strong position owing to the ever present risk that vessels are subjected to in bringing metal to this country. Activity on the part of spelter producers has developed a weak market. Lead is very strong, with independents asking higher prices. Antimony is in less demand and consequently weaker. Aluminum is strong and firm.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Copper.—During the past six weeks the price of metal has shown a decline of approximately 5c per lb. This has largely been caused by the action of the large producers in offering the American Government all the metal they require at a much lower figure than that prevailing on the open market. Coupled with this situation is the fact that consumers are still assuming a waiting attitude, as conditions still tend to uncertainty regarding early future movements. The fact that the greater portion of the first half of 1917 requirements had been contracted for before the beginning of the year leaves the buying element in a position where they can temporarily await developments. In the meantime the market continues to weaken and prices are becoming easier. London reports a decline on all grades, while New York quotations are 1½c lower than last week, the nominal prices being 32c for lake, 31½c for electrolytic, and 28½c for castings. Local quotations are lower, dealers having reduced their prices 1c per lb., the prevailing figures being 37c for lake and electrolytic, and 36c for castings.

Tin.—War rumors to the effect that the United States Government is contemplating the placing of a tax on pig tin has created considerable excitement on the general market. While the freer granting of shipping permits were expected to follow the American war declaration, little relief has been noticed in this connection, but with the gradual formation of a closer co-operative policy this question is expected to receive early attention. A higher market prevails both in London and New York, the latter quotation being 55¾c per lb., this price being ¾c stronger than a week ago. A stronger air pervades the local situation with prices advanced 1½c, the dealers' quotation being 56½c per lb.

Spelter.—The market has been marked by the inactivity of buyers, and with sellers trying to make sales, the situation has developed a weak tendency. Should the dullness continue, still lower prices are anticipated by producers. London is easier and New York is quoting ⅝c below that of a week ago, the current nominal quotation being 9¼c per lb. The quotation on the market here of 12½c represents a decline of 1½c per lb.

Lead.—Firmness features the general lead situation, and this will likely prevail until definite arrangements have been made by the American Government regarding their future requirements. The strength of the situation is also partly due to the action of some producers in refraining from placing surplus supplies upon the market, keeping the metal for early contingencies. The general demand continues fairly heavy, but the present supply is not over abundant. The London situation is firm, with the New York market slightly stronger, the price quoted by independents being ¼c higher than last week, the current quotation being 9¾c per lb. Dealers here continue to quote 12½c on a very strong market.

Antimony.—With a falling off in the demand and the better supply, this metal has developed an easier tendency, and prices have consequently declined. The market is evidently influenced by the uncertain political situation. On a 1½c decline, New York is quoting the nominal price of 34c per lb. Locally the price has declined 1c per lb., the current quotation being 27c.

Machine Tools and Supplies

The machine tool trade has experienced one of the dullest weeks of any during the past few months. The apparent easing off in the demand for shell equipment has resulted in a stagnant situation. The report that the manufacture of the larger sizes of high explosive shells will be discontinued has affected the market to the point where the demand for the heavier tools has become an obsolete factor in the business of machine tool dealers and builders. Present indications seem to be that a quiet spell may feature the early future of this industry. Dealers here report a very quiet week, with practically no inquiries. The demand for all classes of supplies continues very good, although prices are constantly moving upwards. High speed steel is still active, with the price ranging around $2.50 per lb. The uncertainty that prevails among the makers of the larger shells has resulted in a falling off in the demand for supplies in this direction.

Scrap

The present situation is uncertain; dealers are influenced by the unsettled conditions, and it is difficult to state just what scrap is worth. Prices have fluctuated during the week, but are held generally on much the same basis as last week. Metal scraps, such as copper, brass and zinc, are developing a downward tendency, while steel and iron scraps are comparatively strong, with the trend in an opposite direction. With local conditions much the same as last week, dealers are firm on last week's prices.

Toronto, Ont., April 24.—The statement recently issued by the Imperial Munitions Board is striking evidence of what the munition industry has done for Canada. The total expenditure up to March 30, is $543,000,000 while the value of munitions shipped up to that date is $470,000,000. The total value of orders received by the Board is $850,000,000. This activity and the remarkable developments in the steel industry, with which it is closely allied, are responsible more than anything else for the very satisfactory financial and industrial conditions now prevailing in Canada.

Steel

Although prices of steel continue to advance there is some difference of opinion as to the ultimate effect of the influences created by United States entering war, principally by reason of the concessions to the Government by the steel makers. Developments in the U.S. market are being followed closely by the steel trade in Canada, as interests here will be affected beneficially or otherwise by higher or lower prices in the States. In the meantime the trend of prices continues in an upward direction, and in view of the pressure of business at the mills, further advances seem to be the logical result of prevailing conditions. Although bars and small shapes are coming forward in better volume, deliveries on plates and sheets are more backward than ever. A report from Hamilton states that the Steel Company of Canada has closed down a bar mill owing to a let-up in demand for rounds for shells. It is understood that the company is shipping billets to England, in which case there will be no falling off in tonnage output.

Iron and steel bars and small shapes have advanced 25c, and are now quoted as follows:—Iron bars 4.75c, steel bars 5c, and small shapes 5.25c. A leading interest in the United States has announced an advance of $6.00 a ton on all wire products, which will no doubt be followed by higher prices here. An advance in prices on nuts, bolts, and rivets, is also probable in the near future. Makers of iron and steel tubes are sold up for a year or more and are not quoting on new orders. The abnormally heavy demand for ship plates continues, and prices have an upward tendency. Wrought pipe is very firm at the recent advance and makers complain of a scarcity of raw material.

Black sheets continue very firm with indications of higher prices. The new demand for all grades of sheets is considerably greater than the mills can supply. To make the situation worse, production is only about 80 per cent. of capacity and the mills consequently are getting behind on deliveries. The difficulty of geting raw materials is the principal reason for the decrease in output.

The situation in the steel trade in the States is somewhat unsettled although prices are still going up due to the steady increase in demand. The U.S. Government requirements are increasing daily and must continue to do so for an indefinite period. The problem of how to meet the enormous demands for raw and finished steel products is being practically left to solve itself. Tank plates are now being quoted at 6c, and shapes 4c Pittsburgh.

Pig Iron

The situation in the pig iron market is unchanged. A firm quotation on domestic pig iron is practically unobtainable owing to the unsettled conditions prevailing. Hamilton pig iron is off the market and there is very little Victoria iron to be had. At Buffalo the situation is very tight; little iron is being offered at current prices because the output of furnaces is almost completely taken up for the rest of the year. For delivery this year, prices ranging from $42 to $45 are being quoted on pig iron covering the lower to the higher grades.

Scrap

The embargo which hitherto had been placed on the export of steel scrap now includes steel turnings and borings. The result has been a sharp decline in prices of this material to $5 per ton owing to the anticipated accumulation of supplies which cannot in the meantime find a market. The situation will be relieved when the steel plant on Ashbridges Bay is in operation. Heavy melting steel, boiler plate and old rails, are firm and in good demand, as is also No. 1 machinery cast iron. Scrap copper and brass are weaker and prices have declined approximately 1c per lb.

Machine Tools

The machine tool market is gradually assuming a more normal aspect although no great activity is apparent. While the demand for machine tools for munitions plants is now comparatively light, other business is picking up and developments in this regard are looked for. The machine tool market in the States is unsettled owing to the uncertainty with regard to Government requirements. There appears to be a possibility of munitions plants in the States being started up again which would mean a return of the former activity in the machine tool trade. This in time would affect deliveries of machinery to Canada. In the meantime lathes are fairly easy to obtain but deliveries on tool room equipments are very backward.

Supplies

Conditions in the machine shop supply business are improving although prices on most lines continue high. Supplies are now readily obtainable and there is less delay in getting materials than was the case a few months ago. Business generally is nearer normal than it has been for sometime. Gasoline is unchanged in the meantime although the recent advance of 5c a barrel of crude oil may affect prices of gasoline and benzine. Linseed oil has advanced 10c and turpentine 3c a gallon.

Metals

The uncertainty in regard to the American Government's purchases of metals and the fixing of prices on its requirements has caused a weakness in the market. Copper, however, is the only metal which has declined so far, and the market is decidedly weak. Lead is the only metal that is showing any indication of strength, but the price is unchanged meantime. The tin market is unsettled on account of the difficulty of obtaining shipping permits. Spelter is dull and easy, as consumers are not showing any interest in the market.

Copper.—The market is weak and prices have declined. The sales of second-hand copper which have been made, and the persistence of consumers in withholding their orders until price reductions were made have been the principal causes of the weak tone in the copper market. Copper has declined 1c, and is now quoted as follows:—Lake and electrolytic 39c, and castings 38c per pound.

Tin.—Although tin continues to advance in London, prices in New York are unchanged. The outlook in the market in New York is unsettled owing to the difficulty which is being experienced in obtaining shipping permits from the British Government; as a result, tin is not coming forward in sufficient quantities to meet urgent demands, and consumers are becoming uneasy. Local quotations, 56c per pound.

Spelter.—The market is dull and easy, due to lack of interest by consumers. If the demand does not improve, lower prices are likely. Spelter is being quoted at 13c per pound locally.

Lead.—There is a fair inquiry for lead and the market is firm. The position of lead is a strong one, and higher prices are predicted, but in absence of buying demand, no advance has been made. Lead is quoted at 12.25c per pound.

Antimony.—The market is dull, and the demand for spot metal has fallen off. Prices are unchanged and nominal at 36c per pound.

Aluminum.—There is a fair demand for aluminum at unchanged prices. Local quotations, 68c per pound.

Sydney, N.S., April 19.—The conference regarding the coal shortage called by Sir George Foster on the 2nd April at Ottawa, was attended by representatives from all the coal companies of Nova Scotia. The two important factors disclosed were a shortage of labor at the collieries and a shortage of transportation facilities. The decline in the coal production is proportionate to the reduction in the number of workmen employed at the collieries, and no remedy is in sight, as there is absolutely no source from which new workmen to replace those who have enlisted can be obtained, unless the precedent set in France is followed and Asiatic workmen are introduced. It is hardly conceivable that this course will commend itself to anyone, though what the future may enforce cannot be foreseen. The difficulties of transportation arise from a shortage of shipping caused by Admiralty requisitions, and this affects chiefly the Dominion Coal Company. The mainland collieries have been hindered by the inadequate equipment and the very insufficient motive power of the Canadian Government railway, and it is understood an attempt is to be made to improve these conditions.

Coal Famine in Prospect

The prospects of the fuel supply of Montreal and its vicinity in the coming autumn and winter are not cheering from the consumers' viewpoint. The tonnage that will come from the Cape Breton collieries is really negligible compared with previous seasons. The shortage of bottoms on the Great Lakes and the proved inability of the railways to transport the tonnage of coal required by Quebec and Ontario will prevent the sending of an adequate coal supply to these provinces, and there is apparently no way of averting a more pronounced coal famine next winter than was experienced last winter. The price of coal will also continue to advance. A figure of over $5 per ton is already being quoted for bituminous coal at the pit-mouth in Pennsylvania, and it may be confidently predicted that coal will be selling at $7 per ton at the pit-mouth before autumn. When it is stated that the American coal which formerly sold in Montreal against Nova Scotian coal was bought at the pit-mouth at prices varying between $1.50 to $2 per ton, and that the transportation charges have increased in greater ratio than the price of the coal itself, some idea may be gathered of the altitude to which coal prices are likely to soar before next Christmas in that part of Quebec which formerly obtained its coal supply from the Maritime Provinces.

The Minister of Labor has definitely refused to grant a Board of Concilia-

(Continued on page 71).

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46. Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci. Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia. Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

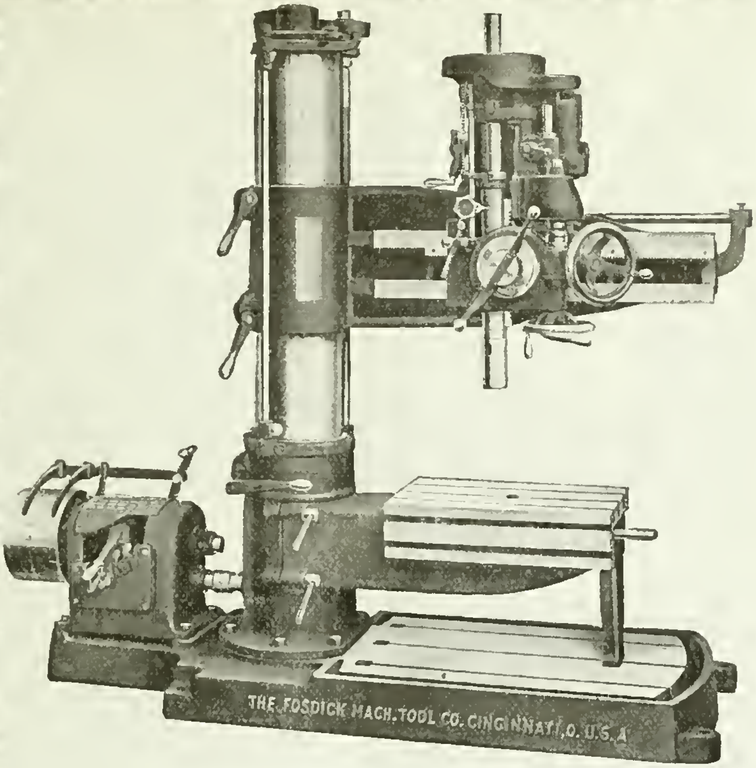
BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbegd No. 4, Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Care British Consulate General, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.



FOSDICK Heavy-duty RADIALS

Will materially increase your production and decrease your manufacturing costs.

Built in two styles, eight sizes, 2 to 6 foot arm.

Speed Box—Cone Pulley or Motor Drive.

Get Catalog and Study Its Money-Saving Features.

Early Deliveries.

The A. R. Williams Machinery Company, Limited

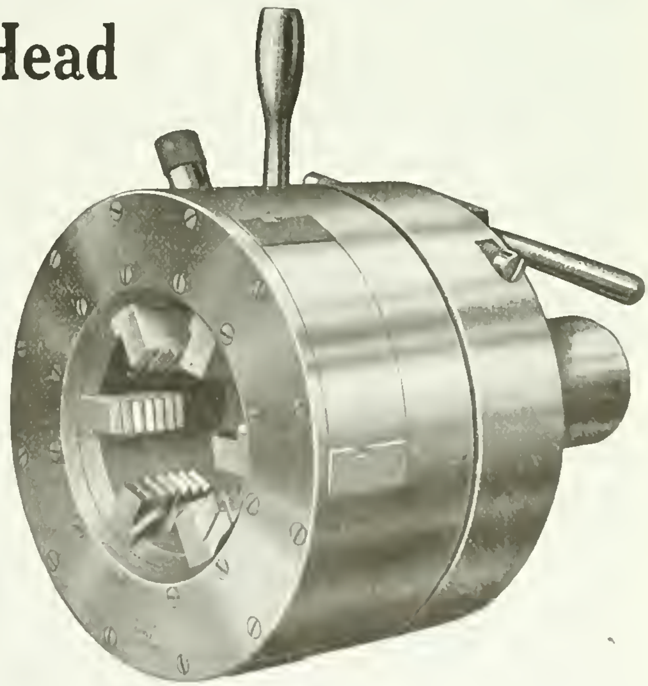
This Geometric Die Head

is making good in a United States Navy Yard. (4½-in. size, Style "D.") It was selected because it was known that it would make good.

One thread is as readily cut as another in a Geometric Self-opening Die Head, because the Head is built for the Thread.

Long threads or short, heavy or light work, large diameters or small, fine threads or coarse—they are all alike to the Geometric Die Head.

Whatever the make of your Screw Machine, a Geometric Self-opening Screw-cutting Die Head can be furnished to fit it. Take up your threading propositions with us.



The Geometric Tool Company, New Haven, Conn., U.S.A.

Canadian Agents:

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

London, Ont.—The Ford Motor Co., propose building an extension to their local plant.

Hamilton, Ont.—The Dominion Steel Foundry are building an addition to their plant.

Midland, Ont.—It is understood that a copper smelting plant will be established here by the International Copper Co. The old blast furnace is being taken down.

Oshawa, Ont.—An extension to the McCullough Brass Foundry is contemplated this summer. A site has been purchased adjoining the plant on the Ritson road.

Three Rivers, Que.—The St. Maurice Lumber Co., propose to erect a power house for six units of 10,500 h.p. and a concrete dam 1,080 feet long. R. F. Grant is manager.

Hamilton, Ont.—The Steel Company of Canada has decided to erect a by-product coke plant. Plans are being prepared, and it is understood construction will start at an early date.

St. Catharines, Ont.—The Globe Shock Absorbing Co. of Canada, which was organized less than a year ago to manufacture a patent automobile tire, has purchased the old Russell-Jennings factory on Vine street, and will immediaately begin the work of enlarging the building and installing new machinery.

Amherstburg, Ont.—The Solvay Process Co. have awarded a contract to the Canadian Bridge Co. for constructing a building here which will be 278 x 192 feet by 80 feet high. The building will be used for housing a number of large tanks. Gordon S. Rutherford is the manager of the local plant.

Port Hope, Ont.—The Nicholson File Co., of which E. M. Thurber is manager, and which has been running night and day to its full capacity on war orders, is desirous of increasing the size of its plant, and wants a fixed assessment of $35,000 for 10 years. It is stated that the monthly pay roll is about $11,000, and the proposed enlargement would increase it by $3,000 or $4,000 per month in wages, as a considerably larger number of men would be employed.

GENERAL

Woodstock, Ont.—The Standard Tube & Fence Co. propose to erect an addition to their factory.

London, Ont.—It is reported that a company propose to establish a plant here for making rubber goods.

Hamilton, Ont.—The Chipman-Holton Knitting Co., are building an extension to their factory to cost about $50,000.

Simcoe, Ont.—Fire, which broke out on April 18 in the east wing of the can plant of the Dominion Canners, Ltd., here, gutted the entire top storey, entailing an estimated loss of $50,000.

Toronto, Ont.—Scythes & Co., 22 Church Street, will build a two-storey brick factory for the manufacture of cordage to cost $20,000.

Winnipeg, Man.—The Dominion Tar & Chemical plant at Transcona, which has been closed down since the beginning of the war, is shortly to resume operations. It is understood the company has just entered into a large contract for creosoting.

Cookshire, Que.—The Imperial Wax Paper Co., a recently incorporated concern, will establish a plant here for making waxed paper by a new process, for which the company has secured the Canadian rights. J. L. McNichol, at present on the staff of McGill University, Montreal, is manager of the company.

Port Arthur, Ont.— Barnett-McQueen, elevator contractors and builders, have been awarded the balance of the contract for the completion of the new 2,500,000 bushel elevator for the Western Terminal Elevator Co. The contract calls for an expenditure of over one million dollars.

Calgary, Alta.—Elevator companies are planning to construct this spring a large number of new storehouses in this province. The Alberta Farmers' Co-operative Co. propose to build 40 new elevators in the province to reach from the Peace River to the southern boundary. The cost of the elevators is placed roughly at $350,000, and the capacity will run all the way from 35,000 to 65,000 bushels each.

Harrow, Ont.—A by-law will be submitted to the electors of Colchester South to be voted on April 30, asking that John Wall & Co., who are proposing to erect a canning factory in the village of Harrow, be exempt from taxation for a term of ten years. In the event of this by-law receiving the required number of votes, the company will commence work on the new factory at once.

Montreal, Que.—Fire on April 20 did approximately $125,000 damage to a factory building on the corner of Nazareth and Brennan streets. The damage to the Independent Silk Co. will amount to $100,000, as much dye, machinery, raw and prepared silks were destroyed. The Montreal Sponging Co., which occupies the second floor, estimates its loss by water at $25,000. The Robert Gardiner Co., who manufacture machinery on the first floor, suffered little damage owing to the splendid work of the Salvage Corps.

MUNICIPAL

Three Rivers, Que.—The City Council propose to instal a waterworks system here.

Hull, P.Q.—The Provincial Board of Health, have ordered the city to install a six million gallon mechanical filtration plant without delay.

Kincardine, Ont.—A by-law will be voted on by the ratepayers on May 15 to authorize a loan of $20,000 to J. B. Watson, who proposes to establish a furniture factory.

Aylmer, Ont.—The ratepayers will vote on a by-law on April 30 to authorize the raising of $22,000 for remodelling the electrical distribution system, and $7,000 for installing an electrically driven fire pump.

Hamilton, Ont.—The Board of Control will adopt a joint report from City Engineer Gray and Waterworks Engineer Bain recommending that additional steam and electric units be installed at the beach pumping house. A resolution has been passed calling on the Board of Control to finance the carrying out of the recommendations, which will invoice an expenditure of approximately $107,000.

TENDERS

Yorkton, Sask.—Tenders will be received until April 30 for one 350-400 b.h.p., combined Diesel electric unit. Specifications may be obtained from F. J. Pilkington, town clerk.

Adamsville, Que.—Tenders will be received up to May 1 for construction of a steel bridge, one span 125 feet, and abutments for same. Plans and specifications can be obtained from O. Landry, Sec-Treasurer, Adamsville.

Montreal South, Que.—Tenders will be called some time in April for a 30-h.p. motor-driven turbine pump and a 150-h.p. gasoline engine-driven turbine pump for fire purposes, etc. E. Drinkwater, St. Lambert, Que., is the engineer.

Toronto, Ont.—Tenders will be received up to May 5, for supply of approximately 100 tons of pure soft pig lead for the York Township. Further information may be obtained at office of Township Engineer, Frank Barber, Toronto.

Edmonton, Alta.—Tenders will be received up to May 1 for the supply of automobile markers for the Province of Alberta, during the year 1918. Specifications may be obtained on application to the Deputy Provincial Secretary, Edmonton, Alta.

Sherbrooke, Que.—Tenders are being called for 30 miles of copper wire, six transformers and other material for a transmission line to Two Mills Falls power plant. Full information may be obtained from J. R. McGregor, electrical superintendent, Sherbrooke.

Toronto, Ont.—Tenders will be received at this Department until May 1, for the erection of a Creamery Building in New Liskeard. Plans and specifications can be seen at the office of the

Agricultural Department, New Liskeard, and this Department, H. F. McNaughton, Secretary, Public Works Department, Tortonto, Ont.

BUILDING

Bridgeburg, Ont.—The School Board is having plans and specifications prepared for a new school, which will cost about $23,000.

Dundas, Ont.—P. H. Secord & Sons of Brantford, have been awarded the contract for erecting a new office building for the John Bertram & Sons Co.

Three Rivers, Que.—The work on the new quarter million dollar post office building, which had been discontinued owing to the war, has now been resumed, and the building is expected to be ready for occupancy about December 1. Contractor Jos. Bourque, of Hull, has been given the contract. Construction of the three municipal schools, the St. Phillippe, the Ste. Cecile schools, and Delasalle Annex, is progressing.

CONTRACTS

Windsor, Ont.—The City Council have awarded a contract to the Canadian Incinerator Co., Toronto, for the construction of an incinerator.

London, Ont.—The Canadian Allis-Chalmers, Ltd., Toronto, have been awarded the contract for the machinery for Hunt Bros.' new mill.

New Toronto, Ont.—The Town Council has awarded a contract to the Herbert Morris Crane & Hoist Co., Toronto, for a jib crane for the waterworks plant.

The John McDougall Caledonian Ironworks, Montreal, have been awarded the contract for motor driven pumping outfit by the town of Hawkesbury, Ont., at $1,569.

New Toronto, Ont.—The contract has been awarded by the council to the Bawden Pump Co., Toronto, for a turbine pump direct connected to a six-cylinder Van Blerck gasoline engine; also for valves and pipe, amounting to about $4,000. Sub-contract amounting to about $1,000 was awarded for valves to the Chapman Valve Mfg. Co., Toronto.

Toronto, Ont.—Tenders for supply of valves and hydrants for the York Township water-works system were opened recently at a meeting of York Township Council. That of the Bawden Machine Co., Toronto, for 14 24-inch valves at $355 each, and one 16-inch valve at $200, was accepted out of five tenders received. The same firm put in the only tender for hydrants at $68.65 each, with three-way foot pipes at $16.25, and additional frost jackets at $12. This tender was also accepted, subject to signing of a contract, approved by the township engineer.

RAILWAYS—BRIDGES

Toronto, Ont.—The Ontario Railway & Municipal Board have ordered the Toronto Street Railway to supply 200 additional cars.

St. Thomas, Ont.—The London and Lake Erie Transportation Co., operating between London and Port Stanley, has offered to sell the portion of its line between St. Thomas and Port Stanley, eight miles, together with four cars, for $168,000.

TRADE GOSSIP

The Chapmen Valve Mfg. Co., Toronto, have been awarded a contract for 24-inch valves for Price Bros., paper mill at Shipsaw Falls, Que.

The Bawden Pump Co., Toronto, have received orders from the British Cordite Co., Nobel, Ont., for nine boiler feed pumps and two general service pumps, and from the Port Arthur Pulp & Paper Co., for eleven centrifugal pumps.

Stratford, Ont.—A reduction of $2 per horse-power to municipalities, announced by the Hydro-Electric Commission, brings the Stratford price down to $27. The local Commission proposes to reduce power and light rates accordingly.

Brantford, Ont. — A reduction of twenty per cent. in domestic, ten per cent. in commercial, and thirteen per cent. in power rates is announced by the Hydro-electric Commission here, meaning a net saving to the consumers for the year of $9,000.

U. S. Steel Unfilled Tonnage.—The unfilled tonnage of the United States Steel Corporation on March 31st was 11,711,644 tons, an increase of 134,947 tons over the previous month, and breaking all previous records. The February tonnage was 11,576,697 tons, which was the previous high record.

Industry Census.—Sir George Foster, acting Premier, announces that a comprehensive census of Canadian industries will be taken for 1917 by the census and statistics office. The idea is to have the fullest possible data in hand with regard to industrial undertakings available for the period of reconstruction, which will follow the return of peace.

Competition for Canada.—Russia will become world's largest exporter of wood pulp for making paper, according to M. Ghambashidze, honorary secretary of Russo-British Chamber of Commerce. in an address to commercial men at Hull, England. He predicted that Russia would eventually utilize her vast forests for manufacture of wood pulp.

Output of Seal Oil Will Be Commandeered.—Advices from St. John's, Newfoundland, state that it is understood that the British Government will commandeer the entire output of seal oil in this colony this year. Glycerine extracted from the oil has been found valuable in the manufacture of explosives. As a result of the assured demand, the price for seal pelts still on the market has risen from last year's quotation of $6 a quintal (112 pounds) to $7.25.

Hamilton, Ont.—In order to provide for contemplated additions to the plant, the directors of the Canadian Shovel & Tool Co. have decided to increase their capitalization from $150,000 to $500,000. Official notification has been received from Ottawa, stating that the concern has been reincorporated with the increasd capitalization. The directorate is composed of W. A. Holton, F. Skelton, W. E. Skelton, M. B. Holton, and L. J. Holton.

Trail, B.C.—Shipments of refined copper and zinc from the Trail refinery of the Consolidated Mining & Smelting Co. are said to be going forward at a favorable rate. Copper is being shipped at the rate of between twenty-two and twenty-three tons per day, while zinc is going forward at an average rate of thirty-two to thirty-three tons daily. The output of the refinery is contracted for by the Imperial Munitions Board.

Move Plant From U. S. to Canada.—The proprietor of a spruce sawmill in New York State, whose timber limits are exhausted, has notified the Department of Trade and Commerce, Ottawa, of his wish to move to Canada. He is prepared to establish a plant with an outfit of 80,000 feet per day and wishes to locate in a town with good railway facilities and convenient to spruce timber limits that are on the market either for sale or lease.

Canada Steamship Earnings Unaffected.—The new British order requisitioning all vessels under the British flag is not expected to have any material effect on the earnings of the Canada Steamship Lines, as it is pointed out fully nine-tenths of the company's fleet are under charter to the French Government and are not available until next February at the earliest. A director points out that such being the case the new order will make little change in the revenue of the company.

Hamilton, Ont. — The Provincial Hydro-Electric Commission has consented to a fifteen per cent. reduction in the commercial lighting rates, thus enabling the Hamilton Hydro department to compete on more equitable terms with the Cataract Power Co. A reduction of twenty per cent. in power rates for manufacturing purposes has also been agreed to, which will make it possible for the department to undersell the private company in dealing with new industries.

First Train Runs Under Mountain.—The first electric locomotive ran through the Mount Royal Tunnel, Montreal, on April 16, from the west portal at Model City through to the Dorchester Street shaft. A complete track is now laid through the tunnel. It is single part of the road and double where two trains are to pass each other. A complete double track will be laid later. The inside of the tunnel is now virtually completed. As yet, only construction trains will be run under the mountain.

Railways Seek to Raise Rates.—The Canadian railroads are about to make application to the Board of Railway Commissioners for a 15 per cent. increase in freight rates, and also a 15 per cent. increase in passenger rates. The railway companies state that this action has been rendered necessary by in freight and passenger rates will not be sufficient to meet even the increased cost of fuel, not to mention a 90 per the staggering additions to operating expenses. These include an advance of about 100 per cent. in the price of coal, and in addition a duty of 53c per ton on locomotive fuel entering Canada from the United States, and a 7½ per cent. surtax in connection with war revenue. They claim that the proposed increases cent. increase in the price of locomotives, 50 per cent. increase in passenger and freight cars, rails $10 a ton more than formerly.

Ford Gives Tractor Patents to Britain.—Henry Ford, at the request of the British Government, has waived all patent rights on his farm tractor and has cabled the specifications to London, so that Great Britain can manufacture tractors for use in the British Isles and France. Announcement to this effect was made at the Ford Motor Co.'s offices, Detroit, Mich., recently. It is believed that the tractors will help to greatly increase farm acreage in the Entente countries. It also was announced that Mr. Ford hopes to have thousands of tractors ready for use in the United States and Canada by August 1. Mr. Ford's entire tractor plant, the same as his automobile factory, will be at the disposal of the United States Government.

"Imperial" Building for the C.N.E.—The Dominion Royal Commission appointed by the Imperial Government several years ago to investigate and report upon the resources of the Empire, has recommended to the British Government that a grant be provided for the erection at the Canadian National Exhibition, Toronto, of a permanent building for showing goods of the United Kingdom. An interim report of the Commission just received at the Parliament Buildings deals with the splendid work done by the Exhibition, and the needs for greater advertisement of British goods. Goods manufactured in the United States, the Commission found, are now given undue prominence compared with those of Canada's Mother Country. The Commission since its appointment, has traveled over the whole Empire.

Toronto Harbor Improvements.—Contracts amounting to $600,000 for pierhead construction work have been awarded by the Toronto Harbor Commission. The work is split among three concerns—R. Weddell & Sons, Trenton and Toronto; Port Arthur Construction Co., and J. O. Roddick, Toronto. The three contracts will constitute the summer work on the harbor improvement, and call for the construction of crib substructures and concrete superstructure of the inner harbor wall from Bathurst street east to York street. The total distance is 6,000 feet, so each concern contracts to construct 2,000 feet of wall. Section No. 3, immediately east from Bathurst street, will be built by the Weddell concern; J. O. Roddick will construct centre section No. 4, and the last stretch of pierhead to York street will be put in by the Port Arthur Construction Co.

MARINE

Wellan Canal Open.—The Welland Canal was opened at Port Dalhousie on April 18 for any traffic that comes. All bridge and lock tenders have been put on duty.

Sarnia, Ont.—Work on the Northern Navigation Co.'s steamers Hamonic and Huronic is about completed. They have been thoroughly overhauled and repaired.

Victoria, B.C.—The auxiliary schooner Margaret Haney built by the Cameron-Genoa Mills Co., underwent a successful trial cruise on April 5 and is now preparing for a trip to Bombay, India, with a cargo of lumber.

Victoria, B.C.—At the plant of the Cameron-Genoa Mills Co., work on the fourth auxiliary schooner, the Esquimalt is progressing favorably and in a short time the builders will be able to announce definitely the date on which she will be launched.

Vancouver, B.C.—The G.T.P. liner Prince Rupert, which ran ashore on Glenn Island on March 23, was floated shortly after midnight, Saturday, April 21, and is now in the harbor of Prince Rupert. Temporary repairs will be carried out in order to strengthen her for the voyage to Esquimalt, where extensive permanent repairs will be carried out.

Sarnia, Ont.—The Collingwood, Owen Sound, Soo, and north shore ports of Georgian Bay route of the Northern Navigation Co., will not be opened this season owing to the inability of the company to secure a suitable boat. This was announced by E. W. Holton, general passenger agent of the company. Efforts have been made to secure a boat that would fit the service, but repeated failures have been reported.

Victoria, B.C.—The next auxiliary schooner to be launched at the Wallace Shipyards, North Vancouver, is the Jesse Norcross. Although the date for launching has not yet been definitely set, the vessel is practically all ready and it is expected that she will take the water before the end of the month. The Norcross will be the third schooner launched from the ways at Wallace shipyard No. 2 and she will be the fifth vessel afloat of the fleet of wooden ships building in the province.

Sarnia, Ont.—The Reid Wrecking Co., has sold its Canadian interests to the Canada Steamship Line. It is understood that the deal includes the tugs James Reid, Sarnia City and Smith, all powerful towing craft, besides the Sarnia docks and machine shops of the line. The eRids still have the Fischer and Manistique tugs and the dry-dock at Port Huron. The company has also sold the steamer Kongo to Muskeegon parties, and her name will be changed to the Overland.

Government Buys Coal Steamers.—The Dominion Government through the Department of Railways and Canals has concluded the purchase of two steamers, the Drummond and the McKee, to be used in the coal-carrying trade between Sydney and Montreal. The ships, which are of substantial carrying capacity , were secured from the Algoma

Companies. Particular efforts are being put forth both to increase the coal production in Nova Scotia and to improve the carrying facilities.

Vancouver, B.C.—Construction operations on Walls & Co.'s marine ways on Hastings Townsite, has been commenced. The new slip will be 75 feet by 30 feet, and will accommodate an 80-foot vessel with a 10-foot draught. The plant will be fitted to receive repair work in about a month. The president of the company, P. Walls, has had twenty-eight years' experience in shipbuilding in the Old Country, the United States and Canada. He has been a resident of Vancouver for six years, and is well known here.

Extend Embargo on Shipping.—An Order-in-Council has been passed extending the measures taken previously by the Government for the conservation of shipping. The transfer of British ships was restricted and made subject to Government control last year following similar action by the Imperial Government. The embargo has now been extended to cover ship mortgages and mortgage transfer. This action like the first, follows an Imperial regulation.

INCORPORATIONS

The Vancouver Engineering Works of Vancouver, B.C., has been incorporated with a capital of $1,000,000.

The North Shore Ironworks of Vancouver, B.C., has been incorporated with a capital of $100,000.

Akerberg, Thomson & Co., of Prince Rupert, B.C., have been incorporated with a capital of $45,000 to carry on a general engineering business.

Smelters, Ltd., has been incorporated at Ottawa, with a capital of $45,000, to manufacture, smelt, refine metals of all kinds at Montreal. Incorporators are: Peter Bercovith, Ernest Lafontaine and Nathan Gordon, all of Montreal.

Perfect Machine Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture machine tools at Galt, Ont. The provisional directors are: Wesley Clark, John S. Rumble and William B. Call, all of Galt, Ont.

The Davis-Bournonville Co., has been granted an Ontario Provincial license to manufacture cutting and welding apparatus with a capital not to exceed $40,000. The company's attorney is Thomas D. Sutherland of Niagara Falls, Ont.

Atlas Gas & Oil Co. has been incorporated at Toronto, with a capital of $300,000, to acquire and develop oil and gas lands. Head office at Toronto, and provisional directors are: F. W. Sawtell, R. J. M. Gardner and W. N. Houle, all of Toronto.

The Solvay Process Co., has been authorized to carry on business in the Province of Ontario with a capital not exceeding $40,000. The company will manufacture chemical products at Amherstburg, Ont. The Attorney is James S. Lovell of Toronto.

F. X. Truck & Auto Co. of Canada, Ltd., has been incorporated at Ottawa, to manufacture automobiles and motor trucks of all kinds at Walkerville, Ont. The incorporators are Stephen A. Griggs, Edwin H. Collins, and Elihu C. Griggs, all of Walkerville, Ont.

International Equipment Co. has been incorporated at Ottawa, with a capital of $250,000, to manufacture and deal in all kinds of railway, marine and foundry supplies at Montreal. The incorporators are: Arnold Wainwright, Aubrey H. Elder, and D. Burley-Smith, all of Montreal.

Boat Releasing Gear of Canada, Ltd., has been incorporated at Ottawa, with a capital of $226,000, to manufacture boat releasing gear and other appliances Head office is at Montreal, and the incorporators are: Arthur R. Holden, Pierre A. Badeaux, and Arthur Charters, all of Montreal.

The Canadian Shovel & Tool Co., has been incorporated at Ottawa with a capital of $500,000 to manufacture shovels, spades, railway field and mining tools of all kinds at Hamilton, Ont. The incorporators are William A. Holton, Frederick Skelton and Walter E. Skelton all of Hamilton, Ont.

The Mason Regulator & Engineering Co., has been incorporated at Ottawa with a capital of $48,000 to manufacture munitions and to carry on the business of mechanical engineers at Montreal. The incorporators are Henri and Joseph Henri Gerin-Lajoie, and Alexandre Lacoste all of Montreal.

The W. E. Seagrave Co., has been incorporated at Ottawa with a capital of $400,000 to manufacture fire engines and fire apparatus of all kinds at Walkerville, Ont. The incorporators are Warren E. Seagrave of Walkerville and George M. Mair and Alexander R. Bartlett of Windsor, Ont.

Roelofson Elevator Works, Ltd., has been incorporated at Toronto, with a capital of $75,000, to manufacture hand, power, electric and hydraulic elevators at Galt, Ont. The provisional directors are: John F. Roelofson, Edward C. Codling and Harry Smith, all of Galt, Ont.

Independent Metal Co. has been incorporated at Toronto, with a capital of $100,000, to manufacture metals and alloys of all kinds at Toronto. Provisional directors are: James J. Maclennan, John N. Black, and E. Corrigan, all of Toronto.

CATALOGUES

Safety Glasses.—Bulletin issued by T. A. Willson & Co., Inc., Reading, Pa., dealing with various styles of safety glasses for industrial uses. Each style is illustrated and described together with price lists of the glasses and extra parts.

Spraco Paint Gun.—The Spray Enginering Co., Boston, Mass., have issued a bulletin describing the "Spraco" paint gun for all kinds of painting. The principal features of this apparatus and attachments are illustrated and described accompanied by price lists of the complete equipments and also of the auxiliary apparatus.

Niagara Motors.—Bulletin being distributed by the Niagara Motors Corporation, Buffalo, N.Y., dealing with an interesting line of gasoline motors for power boats. Specifications give the principal dimensions and weights, etc., of the various models, some of which are illustrated and their principal features described. A number of power boats are also illustrated featuring the suitability of "Niagara" motors for various kinds of service.

The Worker and the Works is the title of a booklet containing an historical sketch of the Westinghouse Electric and Mfg. Co.'s works at East Pittsburgh, Pa., and also describing the shop welfare work instituted by the company for the benefit of the employees. The Casino Technical Night School operated under the auspices of the company is also dealt with briefly. The illustrations show the night classes at work and also views of the works.

Searchlight Projectors.—An interesting catalogue has recently been issued by Crompton & Co., Chelmsford, England dealing with searchlight projectors for naval and military and general purposes. The catalogue contains a general description covering a wide range of sizes of standard searchlight projectors including particulars of the main features of their construction. The various types are illustrated and particulars given regarding current and range etc. of all sizes. The concluding pages contain information covering special attachments and applications.

BOOK REVIEW

Spon's **Electrical Pocket Book**.. By Walter H. Molesworth. 488 pages 6¾ x 4¼ ins., 325 illustrations. Published by E. & F. N. Spon Ltd., London and Spon and Chamberlain, New York City. Price $1.75 net. This is a new reference book of general electrical information, formulae and tables for practical engineers. The book contains a great deal of useful information for electrical engineers arranged in compact form and written in a clear and concise manner. Some sections, namely, thosedevoted to essentially English practice such as British Board of Trade and Home Office Regulations, etc., will not be of much practical value in Canada, but as it is an English publication this feature could not be eliminated. It is however an excellent handbook and in all other respects will be a valuable reference book for engineers in almost any country. Being a pocket book, questions relating to design and detail have not been included, nor has space permitted of reference to telegraphy, telephoning and special branches of electricity. A useful feature is the inclusion of full metric conversion tables to satisfy the need created by the increasing adoption of metric weights and measures. The book has a synopsis of contents, a complete index comprising 20 pages and is bound in substantial cloth covers.

THE SYDNEY LETTER

(Continued from page 442).

tion to the United Mine Workers of Nova Scotia, but has not yet announced his decision in the matter of the application of the Provincial Workmen's Association. The application of the Provincial Workmen's Association raises a nice technical point. This organization has stated it will not call a strike to enforce its demand for an increase in wages, as the members consider such action at the present juncture would be unpatriotic. This course of action is in every way commendable, but technically it defeats an application for a Board of Conciliation which is supposed to be granted only to prevent the calling of a strike. It would appear as if the Industrial Disputes Act could very usefully be extended to cover the procedure of investigation and conciliation, that has been so successful in the past, in this and similar cases where all that is needed is the tactful aid of some independent and unbiased tribunal to adjust the differences of two parties where the breach of opinion is not so wide as to threaten an actual strike. It is understood that a Commission is to be appointed to investigate the bearing of the increased cost of living on the earnings of the miners, and it is not anticipated that any trouble will occur.

Coal Production

Production at the collieries continues at about the same rate as during the past few months. No increase is being gained, but outputs have not declined materially. Some reduction of the working force is certain when warmer weather arrives, and farming and fishing commence. It is to be hoped the authorities will not permit the wholesale exodus of men from the province which took place last summer when the time for the harvest excursions arrives. The National Service Board will scarcely be able to condone the further reduction of the men employed in producing coal for the increase of the number to be employed in harvesting in the West. This would be a nice example of the procedure known as robbing Peter to pay Paul.

CLASSIFIED ADVERTISING SECTION

Rates (payable in advance): Two cents per word first insertion; one cent per word subsequent insertions. Count five words when box number is required. Each figure counts as one word. Minimum order $1.00. Display rates on application.

WANTED

WANTED—LATHE ABOUT 48" SWING OR larger, also boring mill up to 60". Must be in good order and reasonable price. Apply Box 288, Canadian Machinery. c16m

FOR SALE

1—GISHOLT LATHE 24" SWING, 6' BED, with turret head and three-jaw chuck. 1—Gisholt lathe, same as above, 20" swing, 6' bed. 1—4.5 Brown, Boggs marking machine. Jenckes Machine Co., Sherbrooke, Que. c20m

FOR SALE—ONE 450 H.P. THOMPSON & Williams condensing engine. Will sell cheap. Engine is in first-class repair and will give every satisfaction. Apply J. A. Marven, Limited, Moncton, N.B. tcfm

FORD-SMITH 18-PDR. SHELL GRINDER — complete and in perfect condition. To move quickly we will sell very cheap. M. Beatty & Sons, Ltd., Welland, Ont. c23m

2—SCREW-CUTTING ENGINE LATHES, 14" x 30", complete with countershaft, chuck, face plate, etc. Second-hand, but in good order. 1—Potter and Johnston automatic lathe. Apply The Jenckes Machine Company, Limited, Sherbrooke, Que. c18m

FOR SALE—TWELVE PRACTICALLY NEW No. 7-C Racine heavy duty high speed hack saw machines. Suitable for all cutting purposes. Immediate delivery. For price and further information address The Peck Rolling Mills, Limited, Montreal. c16m

ONE LATHE 16" x 4½' BACK-GEARED — Built by P. P. Silk Machine & Tool Co., Cincinnati, Ohio. One lathe 18" x 3', back-geared. Built by the Bradford Mill Co., Cincinnati, Ohio. Four Murchey collapsible dies. Capacity 1½" to 2½". Box 272, Canadian Machinery. ctmf

FOR IMMEDIATE SALE—1—75 H.P. ELYRIA gas engine; 1—40 H.P. Elyria gas engine; 1—75 Kw., 250-volt D.C. Western Electric generator, belted type; 1—45 Kw., 250-volt D.C. Crocker-Wheeler generator, belted type; 1—45 H.P., 220-volt Westinghouse motor. All in first-class condition; can be inspected in daily use. The Elyria Machine Co., Elyria, Ohio. c16m

WE OFFER THE FOLLOWING MACHINERY and tools at exceptionally low prices: 1—heavy duty Rockford drill, 24", suitable for heavy work, in use only two months; 4—Jones & Lamson turret lathes. Bar machines, size 2 x 24; price $200.00 to $250.00 each. 2—Jones & Lamson turret lathes, chucking machines, size 2 x 24; price $200.00 each. 1—Small turret lathe, 1¾ hole in spindle, 1¼ hole in turret head. 1—Two-spindle sensitive drill, $100.00. 2—Holden-Morgan thread millers, slightly used on 4.5 shells. 4—Bertram internal thread millers. 2—No. 9 Hartness dies, capacity range 1¾ to 3" dia. 4—12" Whiton Universal scroll heavy duty chucks, 3-jaw. 1—10" Skinner Universal chuck, 3-jaw. 1—10 x 12 35 H.P. Robb horizontal steam engine, in first-class condition. Apply Steel Furnishing Company, Limited, New Glasgow, N.S. cow17

PLATING

WE CAN UNDERTAKE AT PRESENT TIME certain quantity of job plating of all kinds, at reasonable figures. Enquire for prices. Renfrew Scale Company, Renfrew, Ont. c18m

SPECIAL MACHINERY

MANUFACTURERS—WE CAN UNDERTAKE work to any specification—munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

O. E. WOODS—GENERAL MACHINE SHOP—builders of special machinery. Will do well to use our experience and equipment. We are prepared to make special machinery, punches and dies, jigs, fixtures and tools to any specifications and drawings. Get our price and promise of delivery. Phone Gerrard 960. Address 754 Broadview Ave., Toronto, Ont.

The same firms—time after time

sending in copy for this section is one of the most convincing proofs of its worth to anyone with machinery or machine shop equipment to dispose of.

These firms know a good thing when they see it—they have learned by using this section just what it can do for them.

Try it yourself! That lathe, drill or whatever it is, describe it fully and send in your copy to-day for next week's issue. You'll find that the frequent use of this section will help you dispose of equipment you have outgrown—get what you want in a hurry, whether it be men or equipment.

BUSINESS CHANCES

A PROSPEROUS AND GROWING FILE manufacturing business. The product is being sold to A1 trade, and the demand is unlimited. This business can be had outright, or the practical partner will remain. A stock company proposition would be considered. This proposition will bear the closest scrutiny. Box 296, Canadian Machinery. c17m

FOR SALE—A MEDIUM-SIZED TWO-STOREY brick factory situated in the best small city in Ontario. Buildings in good condition, suitable for either metal or wood-working; shipping facilities unexcelled. Two trunk lines; direct connections east, west, north and south. Educational advantages the very best. Plant will be sold at a bargain and on easy terms of payment, if desired. Apply Box 294, Canadian Machinery.

SITUATIONS WANTED

SUPERINTENDENT—PRACTICAL MECHANICAL man with 12 years' experience, last two years superintendent of shells, is open for a proposition. Box 289, Canadian Machinery. c16m

SUPERINTENDENT OR WORKS MANAGER of engineering concern will be open for an engagement about 1st of June. Am practical marine engineer with 22 years' experience. Have had 12 years' experience in handling men and am considered good organizer. Marine engine building preferred.—Box 295, Canadian Machinery. c17m

SITUATIONS VACANT

A GENERAL SALESMAN TO HANDLE OUR general lines in part of Ontario. Apply Box 290, Canadian Machinery. c16m

YOUNG MAN WITH GENERAL KNOWLEDGE —to take charge of our sample floor. Apply Box 291, Canadian Machinery. c16m

MECHANICAL ENGINEER WANTED—FIRST-class opportunity for the right party. Must be energetic, ambitious, sober and have some knowledge of French. Apply Box 286, Canadian Machinery. tcmf

PRODUCTION ENGINEER WANTED — TO take charge of cost reduction work in Canadian shop manufacturing air compressors, rock drills and other lines. State age, experience and salary expected. Box 292, Canadian Machinery. c16m

WANTED—A CANADIAN REPRESENTATIVE to handle complete line of electric furnace steel. Must be experienced in handling alloy and tool steels, and now in touch with Canadian trade. Best references required. Box 293, Canadian Machinery. c17m

A GOOD SALES ENGINEER TO OPEN OFfice to sell Moline heat in Canadian territory. Must be a good salesman, having had a general heating and ventilating experience. Must give good references. We have a fine proposition for the right man. Address Moline Heat, Moline, Ill. ctmf

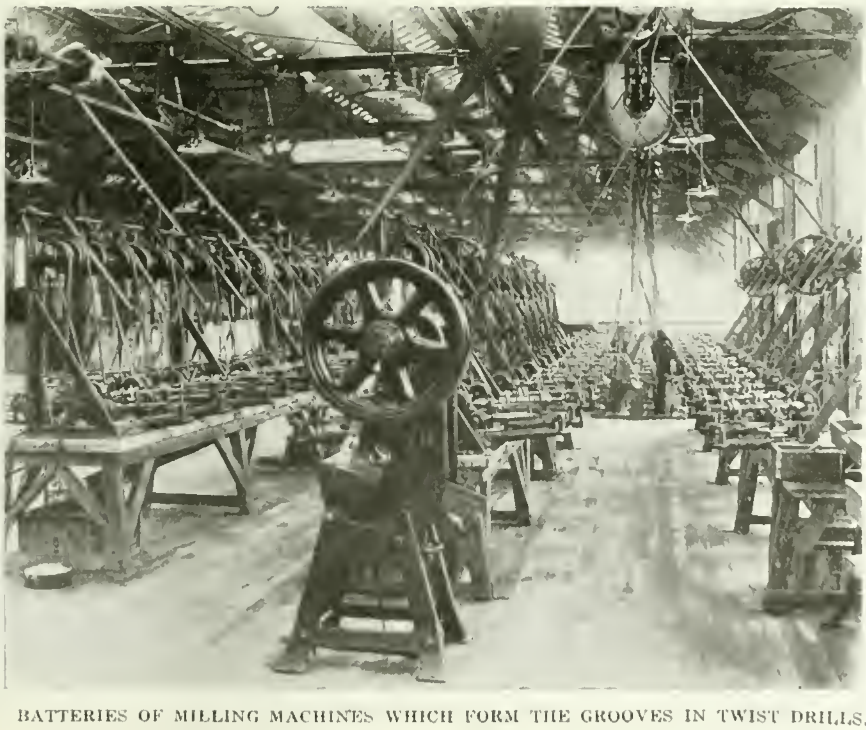
Production of Twist Drills in a Specialized Canadian Factory

Staff Article

Small tools and special items of machine shop equipment, have, in common with machine tools and larger equipment, experienced a period of great demand, although, perhaps due to their lesser intrinsic value, the demand for them has not attracted similar attention. The success attending the efforts of the pioneer twist drill factory in the Dominion is indicative of the results which await organized effort in many allied lines of accessory equipment.

DURING the last three years the demand for machine tools in Canada has been so great and has involved such continuous effort by all branches of the metal working industries that the persistent and consistent growth of accessory manufacturing plants has, to a considerable degree been overlooked.

While twist drills may be classed as an accessory, their functions are so vital to the successful performance of many machine shop operations, that they are well entitled to be classed as a necessity along with taps, reamers, and similar small tools. The industrial growth of the Dominion has been so great that the consumption of this class of product has for some time been large enough to warrant the establishment of a plant devoted entirely to the manufacture of twist drills and concrete evidence of this fact is offered by the Wilt Twist Drill Co. of Canada, Ltd., which since the latter part of 1913 has been engaged in production.



BATTERIES OF MILLING MACHINES WHICH FORM THE GROOVES IN TWIST DRILLS.

The concern was organized in that year by A. D. Wilt, Jr., of Dayton, Ohio, to whose business acumen must be credited the perception of the opportunity and the successful fulfilment of the company's prospects. Operations were commenced on a modest scale at Walkerville, Ont., and from the first facilities had to be rapidly increased to keep pace with the demand for drills until a point was reached which necessitated the erection of an entirely new plant, which would have ample capacity for the now greatly increased demand and allow of suitable future extensions when required. To this end several acres of ground were acquired, situated on Walker Road, Walkerville, and a factory erected thereon during the sum-summer of 1916, occupancy being obtained by the company in September of that year.

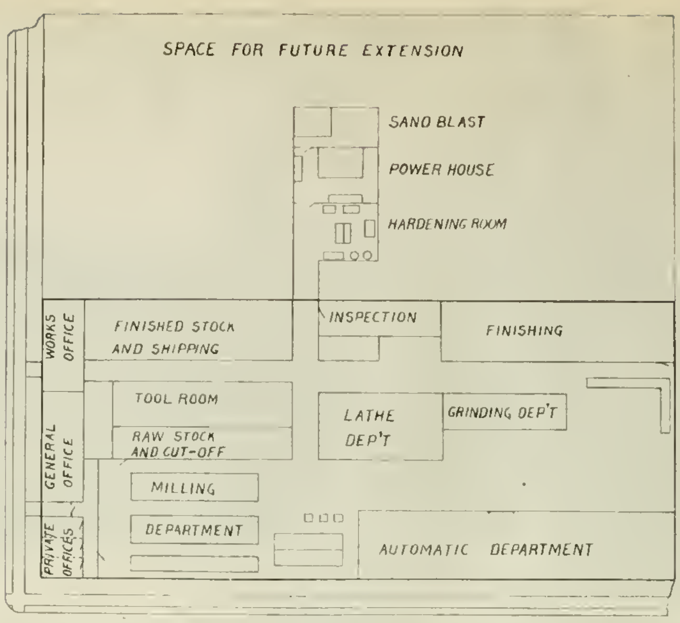
Factory Building

The building is of steel truss design and consists of two bays having a total width of 98 feet, with a length of 228 feet. It was specially designed for the owners by the Austin Co., of Cleveland and in design and construction it represents the most modern type of industrial construction. Particular attention was given to the provision of maximum light and ventilation, the nature of the work rendering the presence of the former a desideratum. As can be observed from the illustration of exterior, this has been accomplished by making each side of building a complete window in itself, combined with the provision of glass panels in the tile roof. The building is therefor entirely enclosed by glass, supported in steel sash of the Trussed Concrete Steel Company's type, there being small brick piers at each corner only. With a few exceptions, where tie-rods would interfere with operation, all the units comprising the openings are fitted with ventilators, and this, combined with the mechanical heating and ventilating system gives purity of air practically equal to outdoors. The roof is of Federal Cement tile, with large glazed areas.

The interior arrangement of the building will be gathered from the views thereof. The steel roof trusses are suitably spaced, and are of convenient section to facilitate the attachment of countershaft beams to their underside. All machines are group driven by overhead motors located near the main columns, of which there is a row down the centre of the shop between the two bays. This arrangement enables machines to be grouped in any desired manner in any part of the shop without any trouble in arranging countershaft drives.

The plan drawing of the factory shows the location of the various departments, the power house, sand blast and hardening rooms being located in a separate building connected to the main building by a covered fire-proof passageway. The power house contains a Goldie & McCulloch return tubular boiler for heating purposes, equipped with Tate-Jones natural gas burning apparatus. In connection with the heating system is a Sirocco blower installation, located in the valley of the roof above the central row of shop columns, from which central location the heated air is distributed through overhead pipes with downward exits.

Other power house equipment includes a 7½ x 6 in. belt driven air compressor by Chicago Pneumatic Tool Co., driven by a 15 horse-power Westinghouse motor, which supplies air for the Franklin sand blast equipment installed by the same firm. Blower requirements for the hardening room are met by a Connersville blower, belt driven from a 15 horsepower Westinghouse motor.



LAYOUT OF FACTORY SHOWING ARRANGEMENT OF DEPARTMENTS.

Twist Drill Features

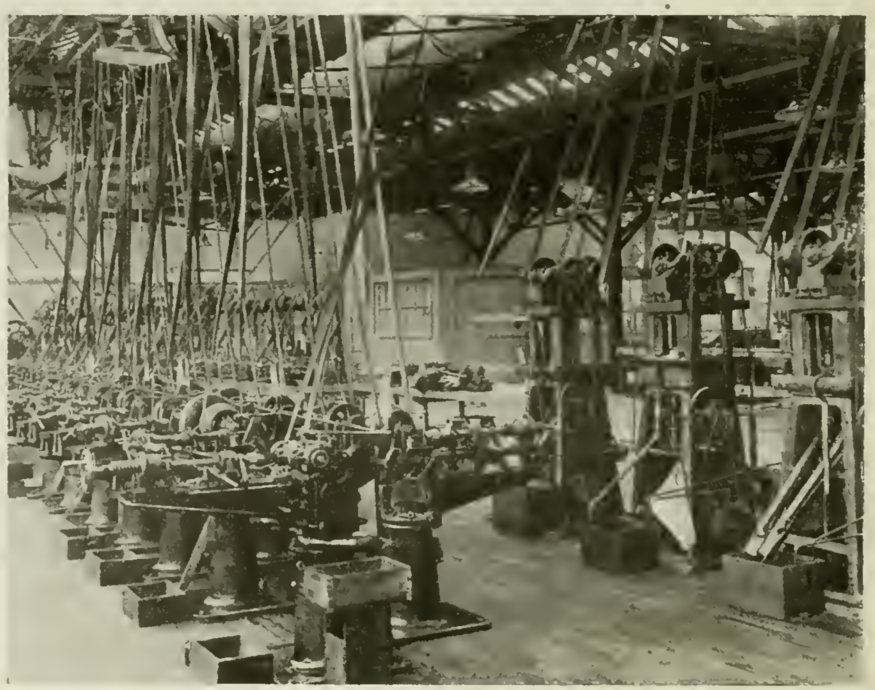
The twist drill, as produced to-day is a precision tool of extreme accuracy and, when viewed in the light of what it can do when given proper treatment, and what it is expected to do with a deal of improper treatment, it is doubtful if any other minor item of machine shop equipment possesses a similar degree of efficiency. While increased costs of material have added to the expense of these, in line with every other product, the fact remains that in normal times, the modern twist drill is practically without an equal in percentage of service rendered for a given cost.

Both carbon and high speed steel drills are produced in all sizes and types regularly in demand by consumers. The facilities of the plant, and nature of the equipment, coupled with hthe extended experience of the staff, enable special drills of a wide variety of types to be produced when occasion requires.

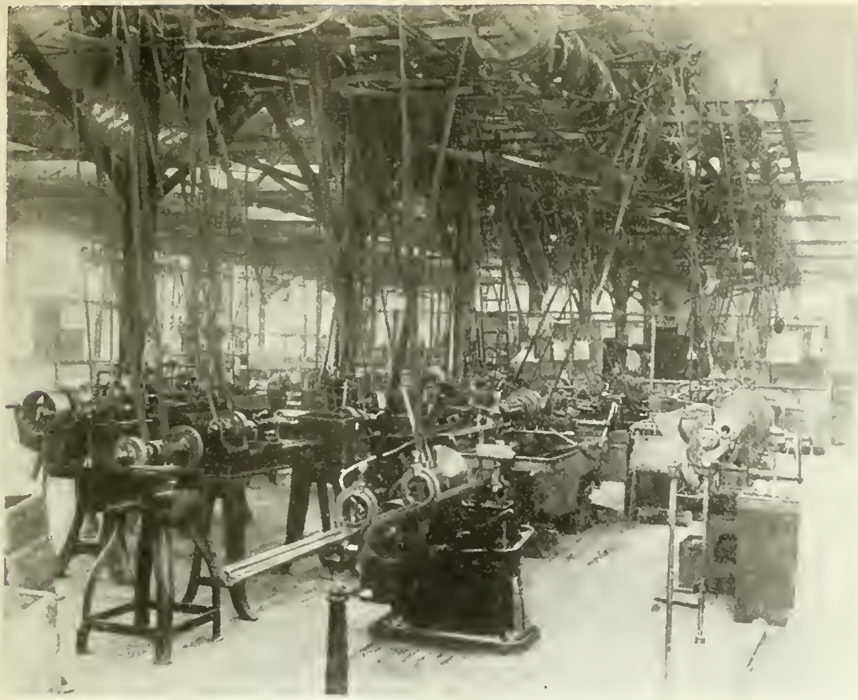
The success attending the efforts of the company to produce a drill perfect in all respects has been largely due to the process developed by them in which the drill is machined complete from the rough stock at one setting instead of undergoing six or seven different machining processes hitherto necessary. The development of special automatic machines for this work has been a feature of the firm's activity, and the success attendant on their operation has enabled them to be adapted to the majority of sizes in general demand.

The necessity for extreme activity even in the rough machining of twist drills will be understood from a study of the diagrams on page 446. Ample chip clearance and free cutting are obtained in Fig. 1 at a sacrifice of strength, so that the strain of operation soon causes collapse, an occurrence which is hastened by the lack of sufficient metal to carry away the heat generated by friction, which greatly reduces the ability of the cutting edge to stand up to the work. The opposite extreme is shown in Fig. 2, where the grooves are so narrow that there is not room for chip clearance, resulting in excessive heat and power required to drive. Fig. 3 shows a perfectly balanced drill such as is produced by the Wilt process, which combines proper chip clearance with ample metal in the web to give strength and carry off heat.

The necessity for proper balance and the exact nature of this feature will be appreciated from a study of Fig. 4; while the condition is exaggerated, the effects are present in any drill which is not correctly machined. Trouble due to this error generally becomes evident in the hardening operation, due to the fact that more metal in one lip than the other causes an unequal strain when the drill is quenched. The quicker contraction of



ANOTHER VIEW OF MILLING DEPARTMENT, SHOWING RELIEVING MACHINES AND SPECIAL VERTICAL MILLERS.



LATHE DEPARTMENT WHERE STOCK IS MACHINED PREPARATORY TO MILLING.

lip A sets up a strain along the centre of the drill C, which is then very liable to crack lengthwise along the web, this cracking frequently taking place before the drill is put into use. Should the drill happen to survive the strain of hardening, the lack of balance makes it impossible to grind it so that each lip will do an equal amount of work, resulting in an excessive strain on lip B, and a hole larger than the drill, and of very imperfect accuracy and finish.

The efforts of the Wilt Co. to develop drill-making machinery of the automatic type have been successful to such an extent that with the exception of small and wire size drills and special large sizes, they are now producing the greater range of sizes in this manner. The demand for small drills is such, however, that a goodly portion of their plant is employed in producing these with standard types of equipment, pending the development of automatic machinery embodying certain improvements and refinements. As the automatic machines combine all of the operations ordinarily performed separately, an outline of the regular routine of drill-making may not be without interest.

Raw Material

All drill material is supplied to specification, either in carbon or high speed steel, and in smooth drawn or hot rolled finish. The bars, rods, or wire, according to the size required, are stored in racks in the stock room, which is equipped with cutting-off machinery as all raw stock is cut to length and pointed before entering on drill making proper. Prominent amongst the machines here is a Cochrane-Bly cold saw equipped with triangular clamps for holding several bars of stock at one time. This machine handles all medium sizes, while a punch press with suitable gauging attachments takes care of all wire size stock. Both ends of the piece are now pointed simultaneously in a special type of speed lathe equipped with a live tailstock spindle which revolves in the same direction as the headstock spindle. Each spindle is equipped with a single blade cutter on the same principle as a pencil sharpener, and while holding the work in pliers with one hand, the operator pulls the tailstock cutter against its end, which forces the other end into the other cutter.

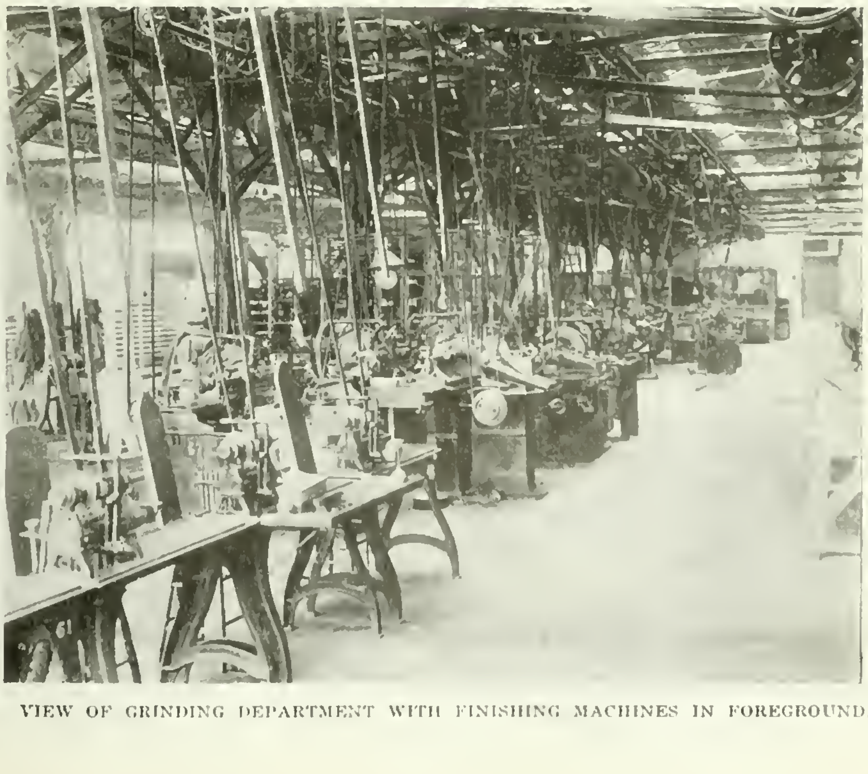
The lathe department is devoted to cutting-off, pointing, body turning, and shank forming on medium and large size drills. The cutting-off is done in powerful hollow spindle lathes after the bar has been pointed in the same machine, after which the shank end is centre drilled and notched with a square spindle when the body is being turned. During this operation the point of the drill blank is supported in a conical cup centre of slightly smaller diameter than the drill body. This method of support and driving is also adopted in lathes which are set up for machining the taper shanks; in this case taper attachments are used to give the correct outline.

Varied requirements in drill specifications necessitate a certain degree of adaptability in the equipment, hence we find special purpose lathes of peculiar design, engine lathes with wide range of capacity, single purpose turret lathes, and several hollow spindle automatic machines of the Cleveland type all occupied on what is more or less straight turning work.

Milling and Relieving

Drill blanks of the proper size are now conveyed to the milling machines, either in the automatic department, or in the small drill department, the latter of which is illustrated on page 443. Here the blanks have the grooves milled and the relief formed on the body. These machines consist of a work holding spindle provided with suitable lead screw for imparting the pitch, the spindle being set at the proper angle to the cutter. The work is supported in a bushing below the cutter, the bushing being cut away on the top side to allow the cutter access to the work and yet give all possible support. Automatic stops drop the work clear of the cutter when the end of the cut is reached, after which the work is drawn back, revolved one hundred and eighty degrees, and the second groove milled.

Relieving on the smaller drills is done



VIEW OF GRINDING DEPARTMENT WITH FINISHING MACHINES IN FOREGROUND.

on a special machine with two end mills which relieve both sides simultaneously. Its general construction is similar to the groove millers, having a lead screw according to pitch, but with the work travelling square to the cutter spindles instead of obliquely in the groove milling. The relieving of wire drills is done by the aid of small grinding wheels in front of which a special bushing is arranged through which the drill passes; one groove engaging a projecting pin which causes the drill to revolve so that as it passes across the face of the wheel from left to right and back again, the proper amount of surface is ground off to form the relief. Before doing this it is necessary to remove all rags, etc., from the grooves and this is performed by hand with a round file; this work is done by girls who acquire a peculiar deftness and lightness of touch so that flattened edges and other results of careless workmanship are very rare.

FIG. 1.

FIG. 2.

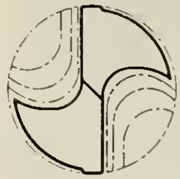


FIG. 3.

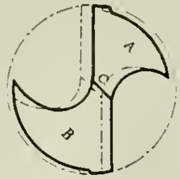

FIG. 4.

Heat Treatment

The marking of the maker's name and drill size is done immediately after milling, so that the drill is now ready for hardening. Every possible precaution dictated by science and experience is taken to impart to the material that condition which is best suited for its work. Not only has the work to be done with an exactitude seldom met with in other lines, but quantity production is likewise a requisite of the equipment. Among interesting items of equipment is a Hoskins electric furnace of the carbon resistance type for obtaining the high temperatures required in hardening alloy steels, the non-oxidizing features of this furnace being a desirable feature when handling highly finished machine work. Gas furnaces, lead baths, oil tempering furnaces, and quenching baths and pyrometer equipment are all evidence of the care exercised in this operation.

Despite all efforts to the contrary, a slight amount of warp will occasionally develop in hardened drills, especially the smaller sizes. As a result of the special heat treatment. there remains ample toughness to allow of the warp being removed with care. Special benches with gas burners, surface plates, and small straightening presses enable this work to be performed with great accuracy and speed, following which the sand blast removes any marks from heating and imparts the fresh clean appearance so typical of new drills.

Finish Grinding

Standard types of grinding machines are employed on the finishing of bodies and shanks. This work calls for a high degree of accuracy and fineness of finish which demand high grade equipment and skilled labor. The drill is driven by a special driver which engages the grooves, and centres the work by the point which has acted as positioning base throughout, the shank end being supported on a centre if tapered, or on a conical cup centre if parallel. On the completion of grinding, a working edge is put on the point of the drill, after which it is ready for shipment.

The upkeep of machinery such as is shown in the various illustrations calls for an efficient tool room installation. The principle requirement, of course, is milling cutters, large numbers of these being used in the course of operations. The cutter blanks are cut off from bars of suitable size in a hacksaw with multiple blades, and are then drilled, machined to size, gashed for teeth and backed off. After hardening, grinding, and sharpening cutters are kept ready for use in the tool crib, their maintenance in good condition being facilitated by the installation of a LeBlond cutter grinder.

Milling machines form a considerable portion of the tool room equipment, including such makes as "Cincinnati," "Milwaukee," and "Le Blond," while, in addition to a full complement of toolroom lathes, there is a special cutter relieving machine of recent type built by the Cleveland Milling Machine Co. Shapers, key-way cutters, drills, etc., balance out the equipment in suitable manner.

BALL BEARINGS

UNDER the auspices of the Society of Engineers (Incorp.) a paper on Ball Bearings was read on April 2 by A. Marshall Arter, F. S. E. A brief resume was given of Prof. Stribeck's investigations.

Before these investigations were made little was known beyond Henry Hertz's theoretical deductions on the contact of elastic bodies. Prof. Stribeck measured the approach of hardened steel balls under compression and found that the admissible static loads varied as the square of the diameter; he also found that ball bearings in which the load is carried at right angles to the axis of rotation of the balls were alone suitable for heavy loads. It was pointed out that the balls in modern ball bearings did not burst, but that the surface flaked out when overloaded, the load-carrying capacity depending upon the elastic limit of the surface of the steel.

The author further pointed out that the ball bearing of to-day could never have been made a commercial success but for the very high degree of accuracy in its manufacture. If a load of 130 lbs. is put upon a ball half an inch in diameter, it is compressed one-thousandth of an inch, and hence if one of the balls in a thrust bearing is one thousandth of an inch larger than the rest, or there is a high place in the race of this amount failure is certain if the normal load of the ball is at all approaching the safe working limit.

The relation of load to speed was dealt with, and it was shown that the safe working load of a ball was reduced on increasing its speed of rotation, in thrust bearings the amount being greater than in radial ones. Prof. Goodman's method of examining balls under a microscope for detecting overloading was explained.

The gyroscopic effects, at high speeds, in thrust bearings was next dealt with. It was shown that there is a certain minimum load necessary to prevent the balls skidding, due to gyroscopic torque, and that there is an absolute limit of speed at which a thrust bearing can be run, namely, when the maximum and minimum loads coincide.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

CENTERING SHELLS

By R. Hamilton.

MACHINING from rough forgings necessitates careful calculations in the preparation of the material for the preliminary operations so that sufficient stock be left on all portions for the finishing of the product. In the case of shells of various types, where the eccentricity of the bore and the outer surface is often a serious question, it is a difficult problem to determine just where to place the centre in the base end so that the machining of the different parts of the shell will conform to the desired specifications. Due to the defects in the forging process, shells are often delivered to the machining plants that require careful judgmeut on the part of the manufacturer in deciding whether any particular shell can be machined without developing additional defects. Owing to the large quantity of shells produced, it has been almost impossible to avoid many of them being forged with eccentric walls, and to prevent the enormous loss that would be entailed by the rejection of all, manufacturers have endeavored to adjust these defects, and have been successful to the extent that large numbers have been saved that otherwise would have reverted to the scrap heap. On account of the difficulties incidental to the boring operations, it has been found advisable to commence the machining of the shells by using the bore as a base. Therefore, when centering the base end preparatory to rough turning the outer diameter, it has been the practice to locate this centre by placing a shell on a suitable post or expanding arbor, either on a drill press or a lathe, so that the centre of the rough bore would coincide with the axis of the drill or lathe spindle.

It subsequently developed however, that many shells were being thrown out because the outside would not clean up, owing to the excessive eccentricity, and in order to save the greater number of these shells it was necessary to draw the base centre over sufficiently to provide stock enough on the low side to finish to the specified dimensions. This process was originally performed by a hand operation; that is, by drawing the centre over with a centre punch and drilling separately. Arising out of this procedure, jigs were developed that would indicate the error at the time it was placed on the centering fixture and, without removing the shell, the jig could be adjusted to permit of the centre hole being placed eccentric with the bore, and thus strike a fair average for the machining of either surface. The device illustrated in Fig. 1 shows the arrangement of a centering attachment that permits of reasonable adjustment to permit of alignment before centering the base. The base of the fixture, which is secured to the drill press footplate, carries the rocking piece A pivoted on the bolt B. This tilting piece is provided with a lug C that comes in contact with a boss on the base, and keeps the shell in a vertical position. The lower portion D of the supporting post is turned eccentric to the upper section of the shell post, the downward thrust being taken by the flange F. The amount of this eccentricity is indicated in the right hand view, and gives a variation of about 3/32 of an inch. A steel ring is placed on the top of this post to fit the inside profile of the rough forging. Fitted to the housing of the drill spindle H, but with a free vertical movement, is the ring gauge I, held in position by the yolk J. which is pivoted at the back end in the bracket K and supported at the outer end by the spring L. When a shell is placed on the fixture, the mandrel is in a horizontal position as shown by the dotted lines, the tilting piece locked by the dog coming in contact with the stop N, this being released by the lever N; the roller table P supplies a convenient means of handling the shells to and from the machine. After the fixture has been raised to the vertical position, the stop C comes in contact with the base and is retained there owing to the weight being located between it and the fulcrum B. The gauge I is then pulled down by hand and, if the shell protrudes on all sides, the hole is drilled; but if the eccentricity is great and the gauge extends over, the post is revolved by the handle O until the shell shows on all sides.

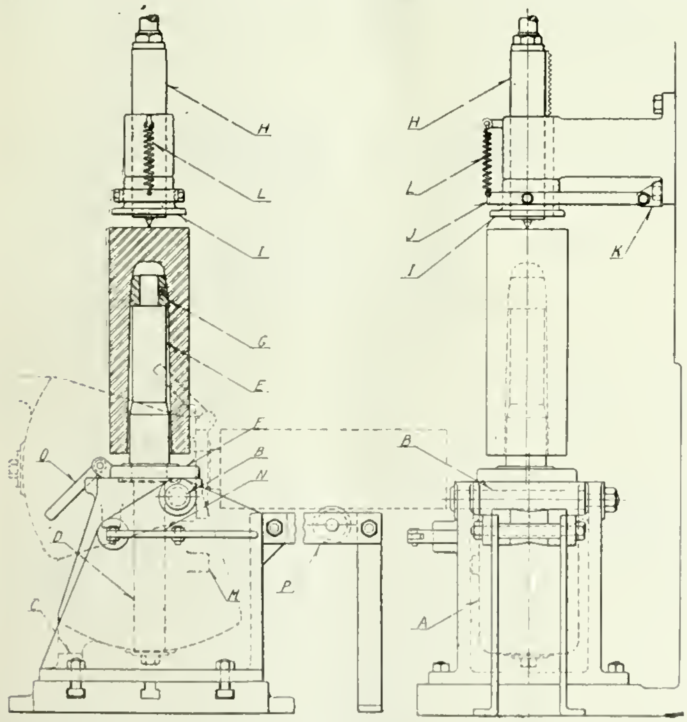

FIG. 1. CENTERING SHELLS.

The object aimed at in the development of the device shown in Fig. 2 was to incorporate effective gauging facilities with the actual operation of centering the base. This fixture was designed so that the shell could be inspected for eccentricity and base thickness as soon as it was placed on the jig, and before the base was centered, in order to discover whether the shells would clean up both on the inside and the outside; in fact, it is intended to eliminate the human equation and make the attachment practically foolproof, not relying on the judgment of the inspector as to how far a centre should be drawn. It should be understood that the principle involved in this fixture may be differentiated to suit the ideas and tools used by the various manufacturers, and its component parts can be changed in proportional dimensions to suit the size of the different shells now being made. The fixture is intended to be fastened to the table of a large single spindle drill in such a manner as to be able to swing the fixture out from under the spindle and back again to a stop fixed on the drill table.

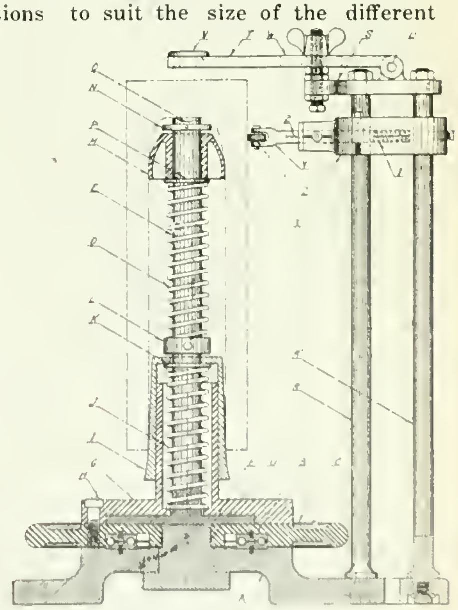

FIG. 2. CENTERING SHELLS.

Fitted to the base A is the double ball

bearing B, upon which the upper portion of the fixture is revolved, the top raceway being secured to the hand wheel C, this being retained in a free working position by the retaining block D. The shell stanchion or post E has a wide flange, eccentric with the shaft, that rests upon the hand wheel C, and is held in position by the piece G, this in turn being locked to the wheel by the screw H. Surrounding the shell portion of the piece G is the tapered bush I, which centralizes the open end of the forging. It will be noticed that space is provided around the post to permit of movement when the shell is being moved to position. To prevent the spring J from interfering with the lateral movement of the stanchion, the plate K is placed about the post to take the thrust of the spring. The collar L serves two purposes, that of controlling the movement of the bush I and to form a seat for the upper spring; this provision being necessary for the independent control of the separate gauging pieces. The top block M is fitted to the shaft in the same manner as the lower one, the washer N determining the upward movement of the piece. The top of the shaft is shaped so that the inner base of the rough forging rests upon four points, as shown at Q. To carry the concentricity gauging apparatus and also the drill jig bracket, the three pillar bolts RR^1 are firmly secured in the base of the fixture. On the upper end of these three bolts the plate bracket S is located, the swinging arm T being pivoted at U, and its outer end carrying the drill bush V. The arm T is provided with a slot W that allows it to be swung clear when the wing nut is released. At a suitable distance down the pillars the collar X is secured; this collar carries the indicator arm Y with a wheel supported in the outer fork. The spring 1 keeps the arm out to its extreme forward position when the shell is in place.

The operation of the fixture may be described as follows:—The scale should be first removed from the inner base of the forging to insure proper contact and avoid false indicating. With the shell in position on the stanchion the jig top T is dropped into position and fastened. A limit gauge, made in any form, is then placed between the top of the shell forging and the bottom of the jig arm, to determine whether there is sufficient metal at the base for finishing. If not, the shell is immediately rejected. If base is of the desired thickness, the indicating arm is released, the tension of the spring 1 forcing it out as far as it will go, thus bringing the wheel Z in contact with the outside of the forging. The fixture, and the shell are then revolved by turning the hand wheel C; if daylight appears between the forging and the indicating wheel, the hand wheel is held stationary and the stanchion revolved through an angle approximating 20 degrees. This action is accomplished by a lever extending out from the flange F and through a slot in the ring G. When the lever is at the rear of the slot, the post is in a central position, and when at the forward end, the bore has been moved from a central position in amount that will still permit of the interior cleaning up to the finished dimensions. The eccentricity is again tested by turning the shell by the hand wheel to determine whether the forging will still clean up. This manner of inspection has involved a certain amount of error being distributed to the bore, but the amount of error so distributed is usually not great enough to prevent the shell cleaning up in the bore, while it also shows whether the shell will clean up on the outside, and this is accomplished with the minimum expenditure of labor. The fixture is then swung under the drill spindle and the center hole drilled.

The slot in the indicating arm should be so placed that when the arm is in the extreme forward position, the outer edge of the wheel Z will be at a distance from the centre of the stanchion equal to one half the diameter of the finished shell, plus the amount of stock that is necessary to finish the outside.

RECLAIMING NUTS

By E. T. S.

THE amount of reclaiming that can be done in the matter of nuts, largely depends on the facilities of the plant in the way of machinery to assist in the production of the serviceable materials. The point having come to our notice that large quantities of nuts were available incidentally, the machine must be made to run backwards. For the large nuts we decided that a couple of old lathes could be fitted up so as to handle the large and medium sized nuts, utilising the tailstock of each lathe to remove the medium sizes on account of that being the weaker end, and the headstocks of each lathe for the large nuts, because it was already fitted with a back gear and ready to run at a suitable speed.

Fig. 1 shows how this has been accomplished. For a chuck to remove the nuts we fitted to the mandril of the lathe a forged steel block that had a taper square hole cut in the center. Of course the smaller sizes go into the chuck a little further than the large ones but that does not affect anything. Hexagon and square nuts all fit into the same chuck, the bolt with the nut projecting forward being traversed into the chuck until the nut is held and turned off. For the large nuts, the regular tool carriage for service if they could only be gotten off the bolts upon which they were either too tight or rusted, led us to believe in and to consider mechanical means of reclaiming same. The first subdivision of whole nuts that would not come off was into three parts, large nuts, those over 1 in. in diameter; medium sized nuts, those between 1 in. in diameter and $\frac{5}{8}$ in., and small nuts those under $\frac{5}{8}$ in. in diameter.

It was obvious that whatever machinery was used it must consist of a gripping device to hold the short end of the bolt, and when a chuck must be made that would take in all sizes of nuts and, was used, the gripping dogs being the grip gear complete from an old Acme bolt threader that had been scrapped.

For the medium sized nuts the tailstock was fitted with a shaft with a similar chuck to the one at the large end, and a belt pulley on the other. For a carriage we cast a large block and bolted a rack, in between the lathe guides, on the bottom of the block. A hole was then bored in the side of the lathe bed for an operating spindle upon which a pinion was placed to mesh in the rack. Another set of threading machine dogs were set on top of the block so that the whole machine was practically reclaimed from scrap. For the large sized nuts, a speed of 28 revolutions per minute was found sufficient, and for the medium sizes it was raised to 40 revs. per min. We have had two of these machines working for the past year now with exceedingly good results.

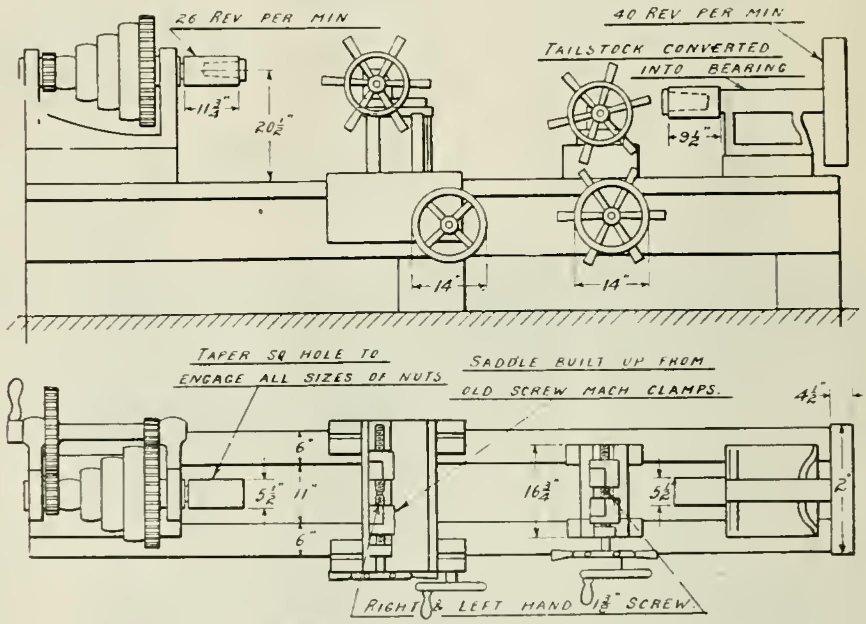

FIG. 1. EQUIPMENT FOR RECLAIMING LARGE NUTS.

For the smaller nuts we found that a lighter mechanism would be more handy, and so decided to use an obsolete drilling machine for the purpose. This was set up and extra keys put in where needed to prevent it loosening up on account of it running backwards. The hand-operated gripping dogs did not operate quick enough on this machine so the

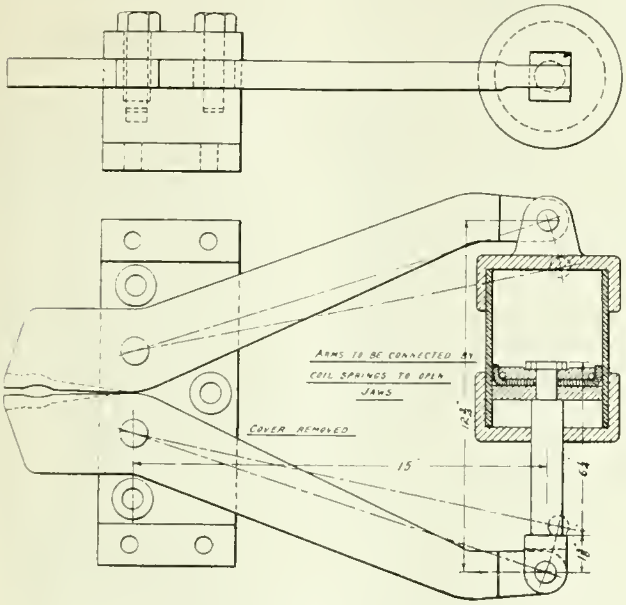

FIG. 2. GRIPPING CLAMP FOR RECLAIMING SMALL NUTS.

pneumatic vise or clamp, Fig. 2, was devised and found to be a great improvement. The operator simply turns a valve and the bolt is securely held. He then pulls down the spindle by means of the lever, the spindle having a nut chuck attached, just as if drilling a hole, and the nut is backed off. When the spindle is raised, the nut drops out, and, when the dogs are released, the bolt drops into a box. After removing nuts from the bolts, we pass them through a tapping machine, so as to be quite sure of the size, also to clean and lubricate same fit for service.

At different times I have heard it said that it does not pay to reclaim nuts. This is entirely wrong for I know that if the question is studied out there is more money in the number of nuts reclaimable than any engineer would admit he was losing by not reclaiming same.

GRINDING PROFILE CUTTERS

By J. H. R.

OWING to the distance that the inner base of the shells is from the open end, it is quite obvious that accurate gauging at this point is largely a matter of guess work; as a matter of fact, much reliance is placed upon the shape of the forming tools that machine this section of the shell, for bringing the base contour to the required shape and dimensions. It is therefore clear that special attention should be given to the problem of construction and subsequent maintenance of these profile cutters. As many of the shell rejections have been directly caused from defects at this particular part of the shell, manufacturers have devised various methods in order to minimize the faults in this connection.

One of the essentials in the satisfactory operation of forming cutters is the accuracy with which they are ground and the devices by which this feature is attained. To eliminate the possibility of error on the part of the machine operator and at the same time ensure a uniform product, attachments have been designed and constructed whereby the cutters can be ground to the closest limits called for in the specifications. Many of these are of a very simple character and demonstrate the remarkable resources that have been uncovered by these past two years of necessity.

The accompanying cuts illustrate two methods by which the grinding of these profile cutters is achieved. Fig. 1 shows the design of an attachment, approved by the Imperial Munitions Board, for the grinding of the base cutters used in finishing the powder cup chamber on the 18-pdr. British shrapnel shell. Mounted on a suitable framework is an adjustable cross slide upon which is secured a portable electric grinder. Parallel to the axis of this grinder an I beam A is located, the upper surface of which is provided with a plate that supports the cutter at the desired height to give the proper clearance to the cutting edge. This plate B is provided with two fixed dowel pins CC, upon which the cutter is located. When grinding the straight portion D which forms the section just above the powder chamber, the plate is moved from its shown position to the desired angle to bring the holes E in line, the fixture being then locked by means of a dowel pin. For the short parallel section F, the fixture is maintained in the position shown, with the dowel in the hole G. The corner radius is derived by swinging the plate and the cutter through an angle of 90 degrees, the radius being determined by the position of the pivot pin H, this being the stud upon which the plate B is connected to the I beam A. To grind the front face I, the plate is swung to the position indicated by the dotted lines, with the finished edge D resting against the gauge piece J, this piece being adjustable and capable of being fixed in a permanent position. When performing the different grinding operations here shown, it should be borne in mind that the opposite side must be worked on alternately in order to maintain a uniform shape. The fixture is operated laterally by means of a suitable slide running parallel to the grinder shaft.

The other device, shown in Fig. 2, was designed for finishing the base profile cutters for the 4.5 inch shells. This attachment was developed by the Jenckes Machine Co. and has been of inestimable value in maintaining the efficiency of these cutters. The base A of cast iron is shaped so that the upper surface upon which the cutter is placed is at an angle with the base in all directions; thus bringing the cutter to the face of the grinding wheel at the desired angle for the proper clearance for every section of the cutter. The gauge C which determines the position for the base of the cutter is secured in a slot so that the gauging face is always at right angle to the axis of the cutter. The wing bolt serves as a locking device when desired position is obtained, the clamp E being used to hold the cutter firmly on the block. Accurate setting of the work is obtained by the screw F. The face of the head of this screw is divided into 50 equal divisions and with a thread of 20-pitch, an adjustment of 1-1000 of an inch is possible; the screw

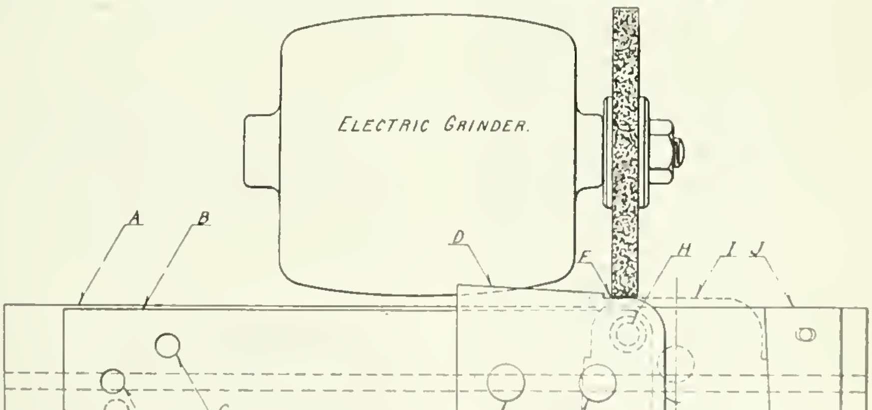

FIG. 1. GRINDING PROFILE CUTTERS.

can be permanently locked in any position by the clamping screw H. The operation of the device is as follows. The cutter is placed on the jig with the gauge C so located as to permit of grinding the face. Before placing the cutter on the jig and clamping in position, the size across the large end should be carefully measured by micrometer and the dimension noted. With the cutter in position and the screw F well back, move the jig towards the grinding wheel until the rolling edges on the pig and table are in contact and then adjust the screw F until the wheel begins to cut. By subtracting the required dimension from that of the unground cutter, the amount of stock to be removed is readily obtained; then the screw F is adjusted by means of the graduations and the indicating point G so that half of this stock is removed from each side. It is desirable however, that if much is to be removed, it should not be done at the one setting but should be first roughed off and finished afterwards by reversing the cutter a couple of times. From the location of the rolling edges and the stop pin I, it is possible to always maintain the tit on the face in a central position. The rolling edge of the table is not shown, but this is a machined ridge on the table surface and located parallel to the axis of the grinding wheel and forward of the wheel sufficient for satisfactory operation.

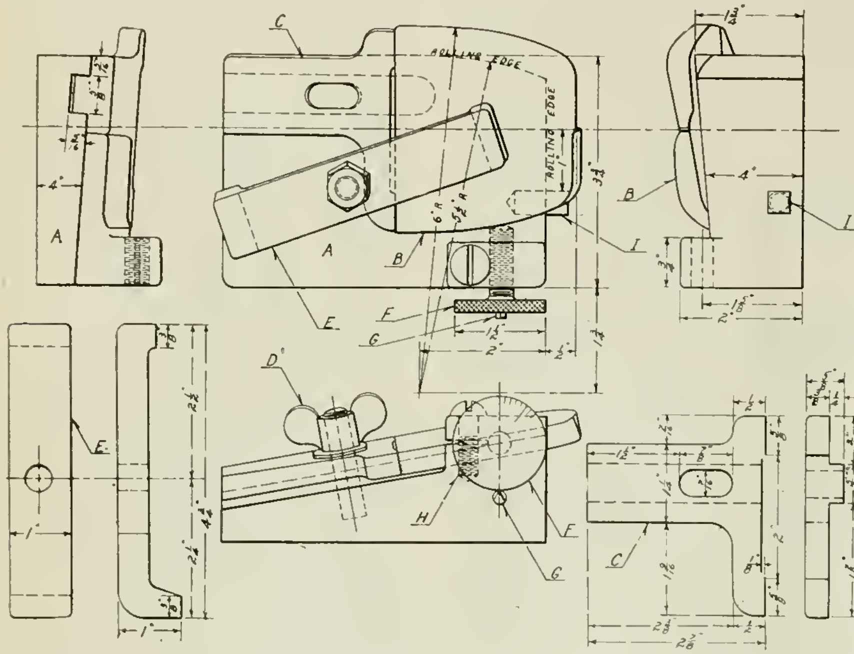

FIG. 2. GRINDING PROFILE CUTTERS.

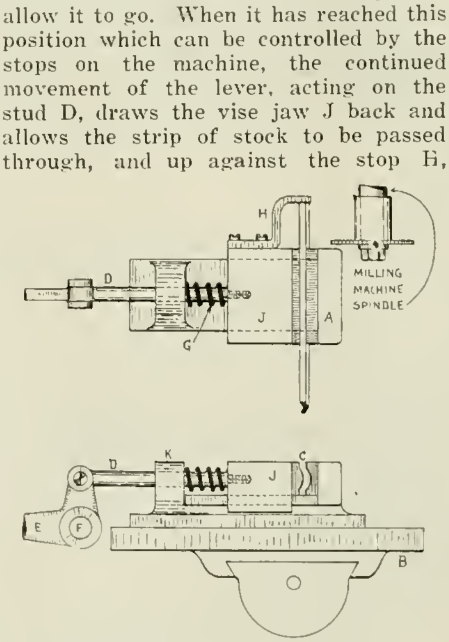
CUTTING OFF STOCK IN THE MILLER

By D. A. Baker.

THE fixture shown herewith should be of general interest on account of its adaptability to other work of a similar nature. In this case it was used for cutting off short lengths from strip brass, which had previously been rolled to a semi-circular form.

Referring to the drawing A is an ordinary milling machine vise, mounted on the table B of a hand miller. The jaws were made, as shown by C, so as not to distort the stock. The regular screw was removed, and in its place was screwed the stud D, which was a sliding fit through K, and was connected to a lever E, which pivoted around the stud F. At G is a heavy coil spring, which is sufficiently powerful to close the jaws of the vise and hold the work securely.

In operation, the lever E is first depressed, thus bringing the milling machine table back as far as the stops will allow it to go. When it has reached this position which can be controlled by the stops on the machine, the continued movement of the lever, acting on the stud D, draws the vise jaw J back and allows the strip of stock to be passed through, and up against the stop H,



CUTTING OFF STOCK IN THE MILLER.

which regulates the length of the piece to be cut. Then by operating the hand lever in the opposite direction the spring G closes the vise jaws on the work, and the lever carries the vise and miller table towards the saw where the piece is sawed off. The efficiency of this fixture on work as illustrated may be judged from the fact that a good man could cut off over a thousand pieces per hour. To be exact, thirteen thousand per day was the average. The same idea can be applied to an infinite variety of work, not necessarily that of cutting up bar stock.

EMBARGO ON STEEL TURNINGS EXPORT

THE Canadian Government placed without warning, effective Saturday afternoon, April 21, an embargo against the shipment of steel shell turnings into the United States. Very considerable amounts had been purchased by consumers in the States, and large tonnages are still due on contracts which cannot now be filled. This scrap is very desirable on account of the analysis and is used in open-hearth practice. For some time an embargo had been in effect against the exportation to the United States, of heavy shell crop ends. The mills of the latter which are shipping billets into Canada for the manufacture of shells and which are large consumers of steel turnings will no doubt insist that the clause in their contracts which provides for the return of the scrap crop ends and turnings to them be complied with.

Production of shell turnings in Canada, it is believed, far exceeds Canadian consumption, and it is known that electric furnaces are being provided at Toronto under Canadian Government auspices, for the conversion of turnings into steel. A similar embargo placed about six months ago was shortly afterward lifted by reason of the inability of the Canadian consumers to take care of their production. The embargo at that time immediately brought the price of turnings down $5 or $6 per ton below what could be obtained on this side. Much adverse criticism is heard on the action in placing this latest embargo, as consumers in Canada have the same opportunity to buy the scrap as American consumers and have generally been given preference at equal figures.

DOMINION BRIDGE GET STRUCTURAL STEEL CONTRACT

THE Department of Railways and Canals of the Canadian Government has placed a contract with the Dominion Bridge Co. of Montreal for 2,500 tons of structural steel for two piers and pier hedss to be constructed in the harbor of Halifax, N.S. The steel will be furnished by the Bethlehem Steel Co. Bids have also been asked on 3,000 tons of structural steel for pier sheds at Quebec, but no award has meantime been announced.

Recent bids on the construction of the second unit of the Eaton department store at Toronto, requiring 12,000 tons of steel, were so high that it was decided to postpone the placing of the contract at this time. It will be recalled that the contract for the first unit was placed in February with the Dominion Bridge Co., and that the steel was ordered from the Bethlehem Steel Co. at $100 per ton f.o.b., Toronto.

Too Holder and Cutting Tool Application Data-III.

By F. Scriber

The approaching return to broader and more general lines of manufacture render a study of tool-holders very timely. While the welded tip has found considerable application under recent conditions of heavy duty and unskilled operation, the obvious advantages of well designed tool-holders are such as to insure a continuance of their use, more especially where variety of work offers increased efficiency opportunities for well assorted equipment.

IN the application of cutting tool holders, the design of the holder depends largely upon the cutter used. In most of the holders previously described, the blades were of such a shape that they could readily be handled for grinding. In the design of the first two holders shown by Fig. 15 which are for cutting forms, the width of the cut being taken makes it impossible to retain this grinding feature to good advantage. The upper view shows a convex cutter A which is made circular in form and beveled for cutting clearance. The cutter itself is is held to the holder B by means of the

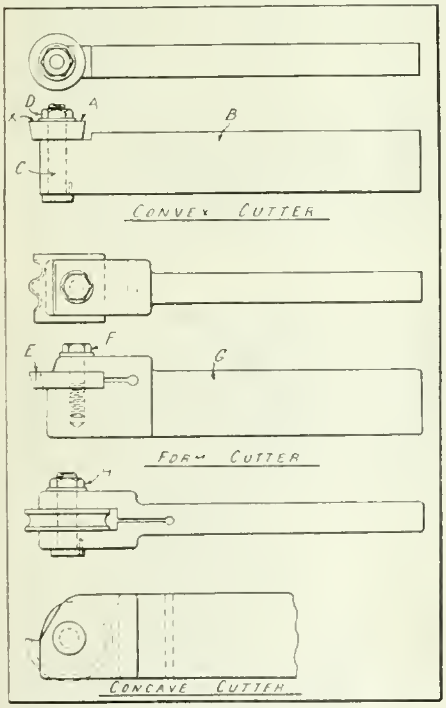


FIG. 15. GROUP OF CUTTERS AND HOLDERS USED FOR FORMING OPERATIONS.

bolt C which is in turn clamped by the nut D. Such a cutter would, of course, machine a concave groove, but is not very economical, as it must be ground on the upper face X. Grinding this face changes the radius of the cutter on account of the bevel, therefore but few grindings can be had, and in consequence it is not a good manufacturing tool.

In the middle view Fig. 15, a formed cuteer E is shown. It is clamped by a screw F, while the holder G has a slot cut in it to receive the cutter, and also another slot to make a spring cutter binding holder of it. This cutter can be ground on the top face and an indefinite number of grinding can be had without changing its shape. The lower view Fig. 15 shows a circular concave cutter held in a spring clamping holder. In this illustration the cutter is seen clamped by the nut and bolt H. It can of course be ground repeatedly in the usual manner as provided for in disc cutters.

Having previously mentioned that this article would show a number of screw cutting tools, Fig. 16 shows three types used. The holders show a fixed clearance angle for the cutter X this being the most economical method of making a threading cutter as the latter is then ground on the top face, and consequently the angle of the tool is not changed. Where the blades are held so that the grinding must be done on the angular sides they are very easily ground out of shape. Referring to the constructional features in the upper view of Fig. 16, the threader cutter is clamped in the same manner as the disc cutter described in the last illustration, but, in addition, this holder carries a screw A, which provides for fine adjustments of the cutter being made. As anyone familiar with threading knows, the threading tool must be set or ground at an angle to conform with the angle of the spiral being cut, otherwise the tool will drag on the thread, and in like manner a threading cutter holder must be made to carry the blade at this angle, although in some cases the ends of the holders are made to swivel so that they can be clamped at various angles, thereby being suitable for quite a number of pitches, either right or left-hand.

In the second illustration, Fig. 16, is shown a threading cutter dovetailed into a holder at B. The blade in this instance is gripped by the wedging action of the clamp C against the back angle of the cutter, while the nut D tightens the clamp C by means of the stud E. Referring to the lower view in Fig. 16, this holder carries a cutter F, which is clamped by means of a strap G. The holder is designed to carry a cutter on either side, as will be evident from the tongue shapes on both sides of the end. This permits of having both ends of the tool ground, when, by reversing the blade and the strap, either end of the cutter may be used.

Mention has been made of the practice of grinding or setting the cutters on an angle to conform with angle of the thread being cut. Fig. 17 illustrates a type of thread cutter holder with a swivel head for this purpose. The shank of the holder A is, of course, held in the tool post in the usual manner, and the head B is clamped to the shank by means of the two screws C. This head contains the thread cutter D, which can be made square or round as required, the particular type shown being round. The cutter is clamped in place by the screw E, besides, another long screw and nut F also help to clamp the swivel head to the holder, while the head swivels on teat X. It will be noticed in the end view that the slots through which the screws C pass are elongated in the swivel head. In operation the head is swiveled to the desired angle, and is then clamped securely; following this the threading is done in the usual manner. The outside angle of these heads is sometimes graduated where noted for convenience in setting the tool.

Referring to the second illustration in Fig. 17, this shows a disc threading cutter G, the cutter being held to the hold-

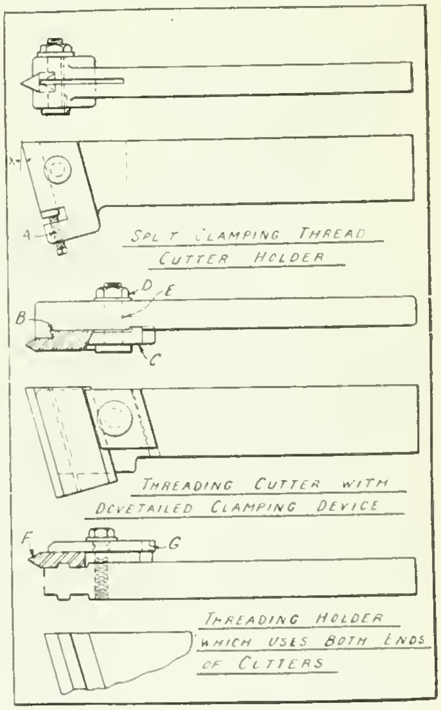

FIG. 16. GROUP OF CUTTERS AND HOLDERS USED FOR THREADING.

er by means of a draw bolt H. This cutter has a tapered portion, which fits in to the holder, thus giving it additional support. The bolt is also tapered at the cutter end and, when this bolt is tightened, the cutter is securely held. It will be noticed that there are no protruding portions at the cutter side of this holder, and, therefore, threading close to a shoulder is easily accomplished. In cutting a thread, it is very apparent that the threading tool will take quite a broad chip, this, of course, depending on the depth of the thread being cut, and as all broad cutting tools have a tendency to hog-in, it has been found advisable in many cases to make the threading tools slightly flexible. These tools are known as spring threading tools, and they are often called goose neck threading tools.

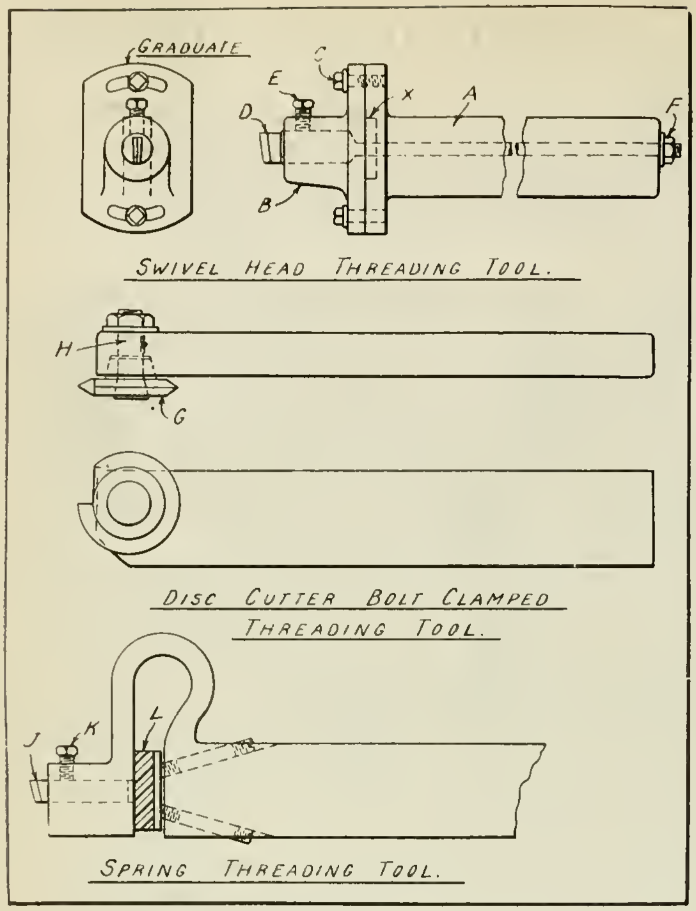

FIG. 17. SWIVEL DISC AND SPRING THREADING TOOLS OF TYPICAL DESIGN.

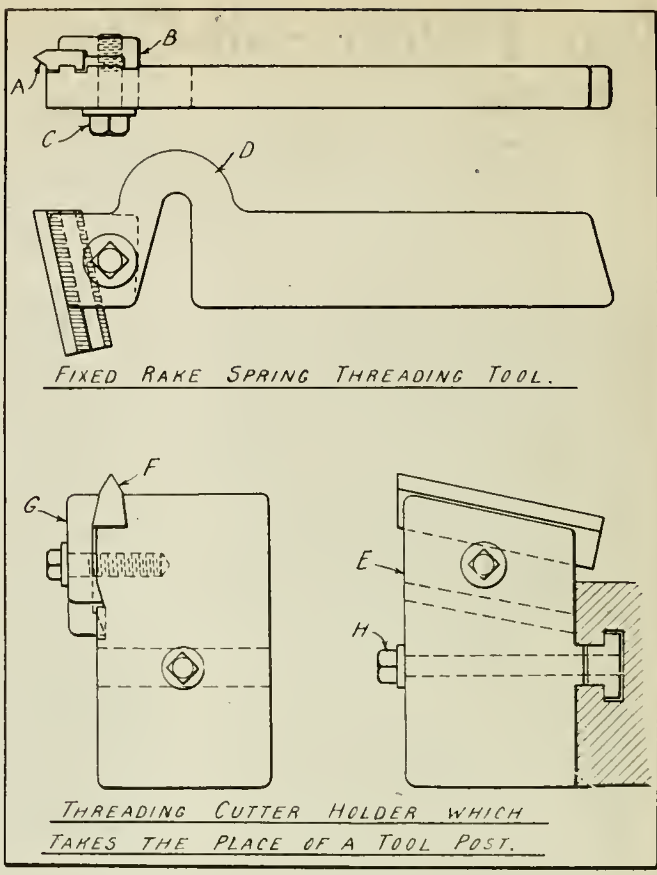

FIG. 18. TWO TOOLS USED FOR THREADING.

The lower view in Fig. 17 shows a threading tool of this type. This tool holds a cutter J, which is clamped by the set screw K. The holder is made in the form of a spring with a hard rubber (or other suitable material) pad L between the holder shank and the part which holds the cutter. This pad is held in position by the two set screws shown, and acts as a butt against which the tool holding portion of the holder comes as it tries to spring away from the cut. By means of the two set screws the amount of elasticity in the tool may be regulated to some extent.

Another spring threading tool which holds the cutter at a fixed clearance rake is illustrated in Fig. 18. In this the cutter A is tongued into the holder, and is clamped by means of the strap B and screw C. The cutter has teeth milled in the side, and when clamped in position will not slide down under a heavy cut. The neck of the tool D must be stiff enough to resist the cutting strain while remaining slightly flexible. In the lower view of Fig. 18 a thread cutter holder, which takes the place of a regular lathe tool post, is shown. This holder is in the form of a block E, which is mounted on cross slide of the lathe. In this block the cutter F is held in the manner shown, and is securely locked in position by means of the screw G, while a screw H holds the block on the cross slide.

Another type of cutter which is quite extensively used in threading is known as a serial point cutter. These cutters are made with a number of teeth, each succeeding tooth being made to remove slightly more than the preceding one. Many of the thread tool holders previously described will handle these serial tools, and the illustration, Fig. 19, shows a thread tool holder with a group of these cutters. The upper illustration in the centre shows a straight holder and an off-set holder. In these the cutter is tongued into the holder, and they are clamped by a screw, which is tightened by a pin wrench. The upper view at the left shows a plain single point cutter, while the upper view at the right shows a single point cutter which cuts the angular portion of the thread, and also cuts the shape at the top of the thread, as in cutting "Whitworth" threads. In the lower view at the extreme left, two off-set single point threading cutters are shown, one of them being but slightly off-set, this being only noticeable on account of one side of the angle being longer than the other. The other, however, is off-set to such an extent as to be very noticeable. In the lower middle views of Fig. 19, a fine and coarse pitch serial threading cutter is shown, while the remaining view at the right shows a threading cutter of a very coarse pitch.

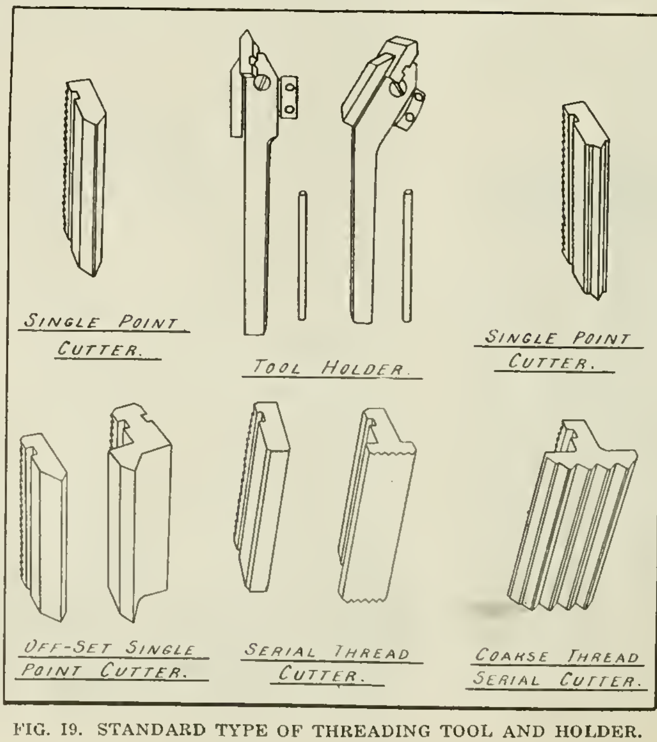

FIG. 19. STANDARD TYPE OF THREADING TOOL AND HOLDER.

Boring Tools

In regard to the problem of boring tools, these are quite varied in design, and consequently but four types will be described in this article, these being confined to lathe boring tools. The first of these shown at the top of Fig 20 is a boring tool holder, which takes the place of a tool post. The view below shows a boring tool which is quite generally used for boring on the milling machine. but may be used to good advantage for some classes of work on the lathe. When used on the lathe it is held in either the lathe spindle or the tailstock spindle, and the cutter is, of course, adjusted by means of the key shown in position at A. This tool bores independently of the cross-slide. An off-set boring tool is shown directly below this. The manner of using the tool is obvious from the illustration, and it might be termed an extension tool post, as it is used similar to the regular tool post while being in turn held to the latter. In the lower view of Fig. 20, a boring tool which replaces the lathe tool post, and will carry a number of different sizes of boring bars, is shown.

Two types of lathe knurling tools, with a group of knurls, are shown in Fig. 21. The principle involved in these two tools is as follows:—The tool at the top contains two studs A and the angular arms which carry the knurls; these are adjusted by the screw B. In the tool holder shown below, this is accomplished by means of a nut C which adjusts the arms D in a vertical plane. This adjusting of the knurls is necessary in order to make them conform to the diameter of the work being machined. In the group of knurls shown below, a fine, medium, and a coarse cut knurl are shown.

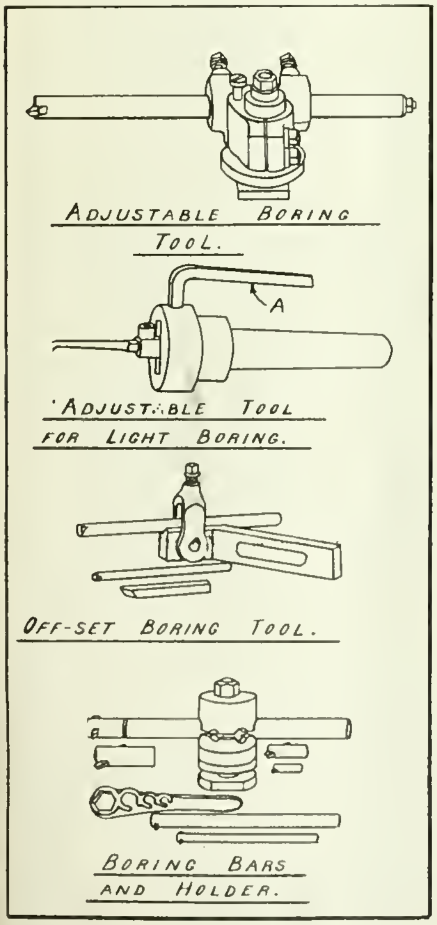

FIG. 20. TOOLS OF STANDARD DESIGN USED FOR BORING.

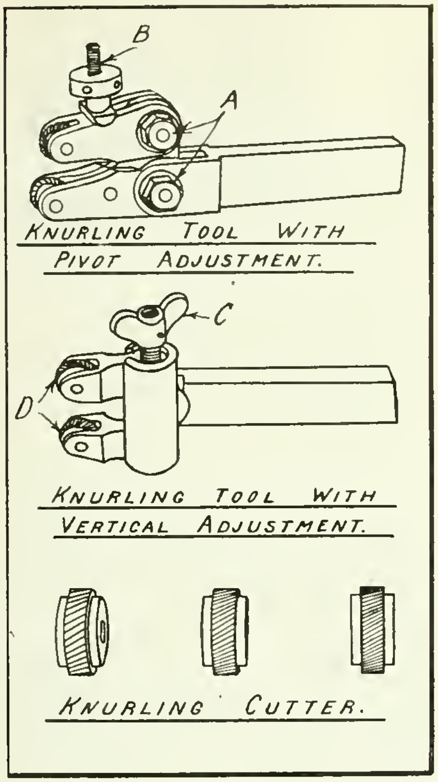

FIG. 21. TWO LATHE TOOLS USED FOR KNURLING.

In presenting this series of articles, it has been the writer's purpose to confine it to the subject of ordinary lathe and planer tools, while avoiding the numerous cutter heads of special design for single purposes; also to show a number of holders which will give good results in their respective fields.

INCREASED TAX ON WAR PROFITS

THE resolution brought down by the Minister of Finance, in the House at Ottawa, to give effect to the proposals contained in his budget speech provides:

1—That in any business taxable under the Act where the annual profits exceed 15 per cent. per annum, the tax shall be increased to 50 per cent. with respect to all profits in excess of the said 15 per cent., but not exceeding 20 per cent. per annum, and where the profits exceed 20 per cent. per annum the tax shall be increased to 75 per cent., with respect to all profits in excess of the said 20 per cent., and such increases as the tax shall be levied against and paid by the person owning such business for each and every accounting period ending after the 31st day of December, 1916.

2—That for the purposes of the said Act, the actual unimpaired reserve, rest or accumulated profits shall, at the commencement of an accounting period by an incorporated company, be included as part of its capital as long as it is held and used by the company as capital.

That any enactment founded on this resolution shall be deemed to have come into force on and from the 18th day of May, 1916.

3—That the tax shall be paid each year within one month from the date of the mailing of the notice of assessment.

4—That with respect to every business liable to taxation hereunder the period for which the returns shall be made and during which it shall be liable for assessment shall be at least thirty-six months. commencing with the beginning of the first accounting period ending after the 31st day of December, 1914, or for such less period as the business may have been carried on from the beginning of the said accounting period to the end of the period for which the said tax may be levied under the said Act.

The following table illustrates the division under the new Profits Taxation Act of a company's profits between the company and the Government:

Profit	Company	Government
10 p.c.	9¼ p.c.	¾ p.c.
15 p.c.	13 p.c.	2 p.c.
20 p.c.	15½ p.c.	4½ p.c.
25 p.c.	16¾ p.c.	8¼ p.c.
30 p.c.	18 p.c.	12 p.c.
50 p.c.	23 p.c.	27 p.c.
100 p.c.	35½ p.c.	64¼ p.c.
200 p.c.	60½ p.c.	139½ p.c.

BIG INCREASE IN DOMINION TRADE

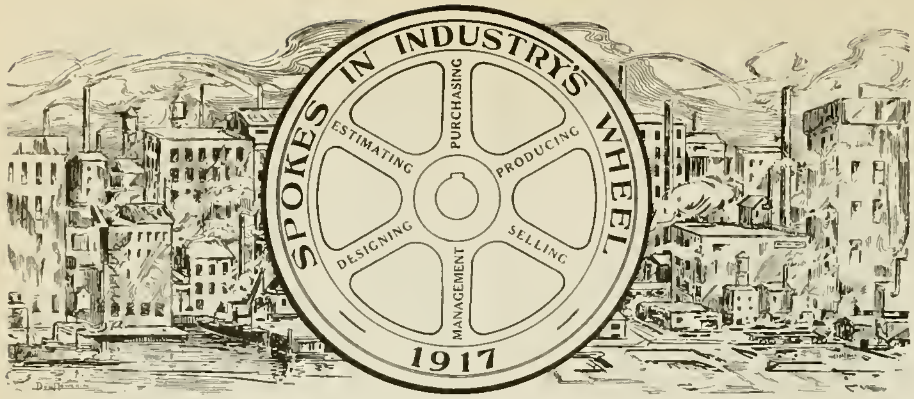
CANADA'S total trade during the fiscal year ended March 31 last exceeded that of the previous financial year by over eight hundred million dollars. Hon. J. D. Reid, Minister of Customs, announced on April 24 that the trade for the year recently terminated amounted to $2,249,-170,171, of which $225,000,000 was in coin and bullion. as compared with $1,-424,916,665, of which $140 000,000 was in coin and bullion in 1915-16.

The exports for the year 1916-17 aggregated $1,151,375,768. as against $741,610,653 in the previous twelve months. Indeed, the great growth in trade was largely due to the expansion in exports of manufactured and agricultural products.

The exports of domestic manufactures increased from $242 034 998 in the fiscal year of 1915-16 to $477 399 676 in 1916-17; agricultural products increased from $249,661,194 to $373,413 701: export of animals and their produce from $102,-882,276 to $127,795,468; products of the mines from $66,589,861 to $85 616 907.

Imports grew from $507,783,361 in 1915-16 to $845,330,903. Of the imports the dutiable goods accounted for $461,-708,206 and free goods for $383 622 697. The Customs revenue was $147 623,230 in 1916-17, as compared with $103,929,-126 in the previous fiscal year.

A leading firm of motor-car builders in England have just been granted a patent on a magnetic non-return valve in which the valve proper is made of hardened magnetized steel and the part of the body on which the seat is formed is of magnetic metal, such as iron.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

WILLIAM NEWMAN

SOME years ago, when a certain shipbuilding yard in the States was making fame for itself through the construction of fast Atlantic liners, it was related of the principal partner that he could go into any department of the plant and replace any workman himself. This thoroughness of training was the formation and mainstay of a particularly close understanding between management and employees, and the almost unique record for efficiency and freedom from trouble in the plant referred to was largely due to the conditions mentioned. Those of our readers acquainted with William Newman, works manager and naval architect of Polson Iron Works, Ltd., Toronto, Ont., will recognize in his interesting career a striking parallel to the conditions related in the opening paragraph. To have developed an intimate knowledge, through personal experience, of all stages in lake shipbuilding from dock newsboy to manager of one of Canada's largest shipbuilding plants is the meantime measure of our Spoke's accomplishment.

Born in Kingston, Ont., Oct. 31, 1873, the son of William Newman and Mary Dehaney, the subject of our sketch early developed that inborn love of boats which was to ultimately influence his life in such large measure. While still at school the attraction of the water was so great that his spare time after school hours was spent in selling papers on the mail boats and other craft with which the waterfront was thronged. With the finish of school days, life's serious work had to be decided on, and accordingly at the early age of 13 years, the "call of the deep" was temporarily suppressed when an apprenticeship was commenced in the Canadian Locomotive Works in his native town. From 1886 to 1890 the duties of a machinist were discharged with considerable ability but even the four years spent in the shade of locomotives did not alter the destiny of our young friend, the "lure of the lake" being so irresistible that immediately his machine-shop apprenticeship was finished he went back to the boats and started to serve his time as an apprentice shipwright in the shipyards of Capt. Robert Davis and the Montreal Transportation Co.

His ability in marine matters was so marked that in the short space of three years he had advanced to the position of foreman in the latter Co.'s yard, a post which he held from 1893 to 1901. The experience which Mr. Newman thus obtained during the receptive period of

WILLIAM NEWMAN.

his life was later to prove of particular value in equipping him for the discharge of ever-increasing responsibilities. During the last six years of this time he did submarine diving for the M. T. Co., and the Donnelly Salvage & Wrecking Co., raising, dry-docking and repairing boats.

From 1901 to 1903, Toronto was the scene of his labors as foreman with the Bertram Shipbuilding Co., which position

superintendent for the late Frank Simp-
superintedent for the late Frank Simpson, C.E., public works contractor, for whom he had charge of laying the six-foot conduit from Lake Ontario to the tunnel under Toronto Bay. All of the floating plant required for this contract was designed and built by him.

On the death of Mr. Simpson in 1908, Mr. Newman became superintendent of the Polson Iron Works, and three years later made a tour of the important shipbuilding plants in Great Britain, France, Belgium, Holland and United States. In the same year, 1911, he was promoted to the post of works manager, and in 1913 undertook the additional duties of naval architect. Mr. Newman looks forward with considerable gratification to the near future when the launching of a number of vessels will mark the completion of the half century of launchings under his supervision, the first of the fifty being the Earl King, launched in 1909.

Notable amongst the work executed during the tenure of his present position are the designs for the big dredge Port Nelson which was built in four months, also the stern-wheel steamer and three steel steam lighters for the Government work at Port Nelson, Hudson Bay. A surpassing effort which is expected to materialize in the near future, however, is a 500-foot electrically operated, steel floating dry-dock, which is to be constructed for the Polson Co.

Mr. Newman's activities further include the managership of the Canadian branch of the American vessel fire register; while he is a member, Naval Architects and Marine Engineers Association, New York; associate member, Institute of Naval Architects, London, Eng.; hon. member, Canadian Society of Marine Engineers; member, Toronto Board of Trade; hon. member, Canadian Quoit Club. He is the possessor of a gold medal presented by the council and citizens of his native city for saving the lives of two women from a burning building while a volunteer member of the fire department, Oct. 2, 1897, and also wears the Diamond Jubilee Medal awarded to representatives of Canadian troops in England on that occasion. His military service includes a twelve-year membership of the 14th Regiment P.W.O.R.; on the outbreak of war he was granted a commission in the 23rd Regiment Northern Pioneers, and is now Captain of No. 5 company.

Mr. Newman owes his success to a large extent to hard work and close attention to details believing in the old adage that it is the little things that count. This principle he has applied to his work with conspicuous success. Some years ago Mr. Newman had the good fortune to meet the late Sir William White the celebrated naval architect, and was much impressed by his personality and kindly advice received on several occasions. Our "Spoke" advises all budding marine engineers to study the career of some man prominent in his profession and considers that no better incentive can be found than in the life of Sir William White, one of whose chief characteristics was a mastery of detail.

While he may deny the fact, our "Spoke" owes not a little of his success to a genial and thoughtful temperament fostered by a study of human nature. During the early part of his career, his occupation gave him plenty of opportunity for observing his fellow men. The knowledge gained has been a valuable asset since, particularly in his present position where he has charge of a large number of men. It is said that when Polsons began to get busy again some eighteen months ago, many old hands who had left when business became slack, returned immediately from all parts on hearing that there was work for them at the old shop. This in itself speaks well for the firm and those in authority.

Mr. Newman being essentially a practical man believes in the practical end of the business. At the same time he strongly advocates the acquisition of the same theory by attendance at night school or college and also by the reading of technical books and journals. He holds that this is necessary for a proper and intelligent understanding of hand books which are of great assistance to those engaged in the construction of ships in any engineering capacity either in the shop or in the drawing office. In his younger days Mr. Newman spent practically all his spare time on study and is deeply indebted to Frank Simpson, for whom he worked at one time, for much valuable assistance and encouragement. He also attended evening classes at Wells Business College, Toronto.

Mr. Newman also states that "there is no institution in Canada where naval architecture is taught, and marine draughtsmen are brought here from Great Britain, Sweden, Denmark and the United States. I think some of our Universities should have a chair in Naval Architecture, as they have in the University of Glasgow and in the School of Technology in Boston, as at the present time, such important positions as loftsman, ship's plater, and ship's carpenter are practically closed to Canadians. There are scarcely a dozen apprentices in Canada to these departments, and outside of the "Old Guard" of ship's carpenter, 90 per cent. of our skilled labor in these branches are brought from outside the Dominion.

"Another industry which Canada must soon take up is the manufacture of ship plates and shapes; also of seamless steel tubes and corrugated furnaces. With her immense wealth of ore, nickel, copper and coal, and her unlimited supply of timber in British Columbia, I see no reason why Canada should not in the future become independent in the shipbuilding trade—something which she is far from being at this writing."

CANADA'S SHELL-MAKING ACHIEVEMENT

THE story of Canada's achievement in the manufacture of munitions was told to the Ottawa branch of the Canadian Society of Civil Engineers on April 25, by Colonel D. Carnegie, a member of the Imperial Munitions Board. He said that when the war broke out Canada's capacity for shell making was confined to three hundred and forty 18-pdr. shrapnel shell per week. Now, she had capacity to turn out 400,000 of the latter per week, including cartridge cases, fuses, propellant, etc., in addition to 400,000 high explosive shells of all varieties—or 800,000 shells per week. To manufacture this huge quantity of munitions requires 25,000 tons of steel per week, 2,500 tons of brass, 750 tons of copper, 250 tons of zinc, 1,500 tons of lead, 200 tons of antimony, 150 tons of resin and 1,300 tons of explosives. The making of boxes required 325,000 lineal feet per week.

Colonel Carnegie said the total value of the shell orders let in Canada had reached the enormous sum of $800,000,000, and there had been shipped to date $500,000,000 worth to France. He emphasized the difficulties at the outset of the manufacturers in making shells. There was difficulty in getting machinery, and a still greater struggle to secure adequate and trained labor. The greatest of all progress had been made by the workers; the skill they had acquired had passed all expectations. So skilled were the Canadian workers now in speed and output that they would excite the admiration of the oldest and most experienced machinists in England.

Shell Factories

There were now 650 factories, distributed through 144 towns (in every province except Prince Edward Island) engaged in turning out shells. He told of the difficulties in securing shell forgings, and the work which was now being accomplished. The value of the steel forging plants was approximately $5,000,000. There had been installed in Canada's factories 18,000 machines for the manufacture of shells, valued at $35,000,000.

In the early stages of the war all our gauges came from the United States, but to-day there were twenty factories in Canada making gauges, and $150,000 per month was spent for gauges. The Imperial Munitions Board had five thousand inspectors, under Colonel Edwards. Col. Carnegie said one of the first projects undertaken by J. W. Flavelle, the present chairman, when he took over the work of the Board, was to establish national factories for the manufacture of shells. To-day there were national factories for loading fuses, making explosives of various kinds, acids and aeroplanes. These were operated by separate companies, the entire stock being held by the Imperial Munitions Board. At the present time the factories are turning out one aeroplane a day, and when the new factories shall have been completed they will have a capacity of five aeroplanes daily.

A Permanent Asset

The factories which had been developed for munition making, he said, would be a permanent asset to Canada for two reasons, first, they had standardized products, and second had standardized skill. No component parts of shells were accepted except under rigid examination, and strict test. Every industry which had been engaged in the manufacture of munitions had passed through processes of refinement. They would return to normal industry after the war much more skilled and competent than before. Munition manufacturing had given an abiding impetus to mining in Canada. The chemical industry, he said, had been accelerated. The electrochemical industry, such as refining copper, which had been developed in the last two or three years, would remain a permanent industry after the war. Every workshop engaged in the munitions industry had standardized skill, which was a permanent asset to Canada. There are now no less than 25,000 skilled workmen, and 12,000 women engaged in munitions manufacture.

Colonel Carnegie predicted an industrial war when peace comes. Germany had been piling up products, which would be thrown on the world's market, and there will be the keenest competition for world commerce. German militarism might be crushed, but German industrial life would be probably stimulated by the war. There would be a struggle for industrial supremacy, and it will take all the ability and experience of Canadian manufacturers to hold their own in this struggle.

SUBMARINE CONSTRUCTION ON PACIFIC COAST

CONSIDERABLE interest is taken in Vancouver's latest acquisition in the way of shipbuilding contracts, particulars of which have just been announced. J. V. Paterson, of Seattle, former president of the Seattle Construction & Dry Dock Co., and one of the best known shipbuilders and marine architects on the Pacific Coast, has closed contracts to build six submarines for the Russian Government. The work will be done at a plant which Mr. Paterson has built in Vancouver, and actual construction of the submarines has been started. Material for all of the half dozen is already on the ground and the plant practically completed, with a force of 150 men now at work. This force will be increased immediately to 350 men, as, while the definite dates of delivery of the vessels are not given out, Mr. Paterson states that they are wanted as quickly as possible.

The order for the submarines is the largest for war vessels for a foreign power yet placed on the Pacific Coast, and is believed to be the only one now pending in Northern yards. A year and a half ago Mr. Paterson built five submarines for the Allies, but he states that these later craft are of a larger and more powerful type than the former order.

MACHINISTS' INSTRUCTION COURSE—XIX

By J. Davies

AFTER deciding how any particular job is to be held in the milling machine, the next point is the selection of a suitable cutter. This is a matter of judgment based on practical experience depending on the nature of the job, the construction of the machine, the rigidity with which the work is held, and last but not least the available supply of cutters to choose from.

Choosing a Cutter

It is quite a common thing to see a milling machine run at considerably less than its maximum capacity for want of suitable cutters; in many cases it is Hobson's choice, this or none. The cutter that will do the work satisfactorily in the least time is the cutter for the job. In a job that would require a number of short cuts, time can be saved by using a cutter of small diameter as a small cutter will pass over a job in less time than a larger cutter would, that is if equal feeds are used. If, however, by using a larger cutter, the greater number of cutting edges on the large cutter would allow an increased feed, nothing would be gained by using a small cutter.

It is very important to keep milling cutter sharp, so much so that many manufacturers have stamped on their milling cutters the words "Keep Sharp." It has been proven that a milling cutter will last much longer if kept absolutely sharp, than it will if used in a dull condition. The dull cutter puts an unnecessary strain upon the machine, the work, and also upon the arbor carrying the cutter, besides the tendency to generate heat in itself and become soft.

Avoid Fine Teeth

Do not choose or make your milling cutters with very fine teeth. It is a mistaken idea to suppose that the finer the teeth the finer the job, or that you can do a job quicker with a milling cutter with fine teeth on account of the greater number of teeth than you could with a wider spaced cutter of the same diameter. If the teeth of your cutter are too fine they are liable to become choked up with cuttings as there is very little chip clearance and you may have to keep on brushing away the chips that have become packed between the teeth.

A proper application of some cutting compound will prevent the chips from clogging up the spaces between the teeth, partly by washing away the chips and partly by changing their character or form, but the chief benefit derived from flooding the work with some kind of lubricant is that it keeps the work and cutter cool and so preserves the cutting edge, allowing a higher rate of feed and speed than would be otherwise possible.

No lubricant is necessary for cutting cast iron, that is soft grey iron, or for yellow brass. For steel, wrought iron, malleable iron, etc., some sort of lubricant is advisable. Lard oil makes a very efficient lubricator for nearly all classes of work, but owing to its cost some sort of soda compound is often used instead. If there is no pump or other mechanical means of applying the cutting compound use a stiff brush and apply to the side of the cutter running away from the work.

Testing the Setting

After securing your work, make a final test to see that it has not moved by the tightening of bolts or clamps. The setting of work that has been secured to the table may be tested for being parallel by a surface gauge from the table, in the same manner as testing a job on the planer. If there is no room on the table or for any other reason a surface gauge cannot be used, a pointer fastened between two washers on the arbor may be used and the table moved under it. A convenient method of setting up an angle plate, parallel with the line of motion of the table,is to put a pointer between two washers on the arbor and bring one end of the plate up until it just touches a feeler or piece of paper placed between the pointer and the plate; then move the table to the other end and test again and adjust until the paper is punched equally at both ends.

For small work the commonest way of securing the work is by a vise the base of which should be graduated in degrees, and have a tongue on the underside to fit one of the slots in the table to ensure it being parallel with the table. The jaws should be of steel and removable, so that special jaws could be made to suit any particular job.

Direction of Feed

Always feed the work against the cutter unless the machine is especially built to feed either way. Some machines one arranged to take care of the backlash existing between the feed screw and the nut, the table being prevented from jumping forward by a weight attached to a cord or chain which passes over a pulley in line with the table. If there is no such appliance always feed against the work Fig. 71 or the cutter will probably draw the work toward itself and climb over it, resulting in a broken cutter or a bent arbor or both.

When setting up work in the vise or on an angle plate where there is a risk of the work slipping, arrange the work so that it will slip from the cutter and not towards it. In taking a light cut that finishes against a radius or shoulder as it is called, be careful as the cutter approaches the end of the cut,—take off the feed and feed very carefully by hand, because if the cutter is allowed to come against a larger mass of metal than it is cutting with any force it will undercut the job. The same remark applies to cutting slots with an end mill—if a slot is cut with an end mill cutting both sides at once, then when the work is fed over again in the opposite direction, the slot will be found to be larger than the mill. The proper way to cut slots is to use an end mill having a diameter slightly less than the width of the slot, and take two cuts one for each side of the slot. If the job must be done in one cut, avoid the common error of setting up the work to cut an equal amount off each side, as the resistance on the side of the mill that is against the cut is not equal to the resistance that is

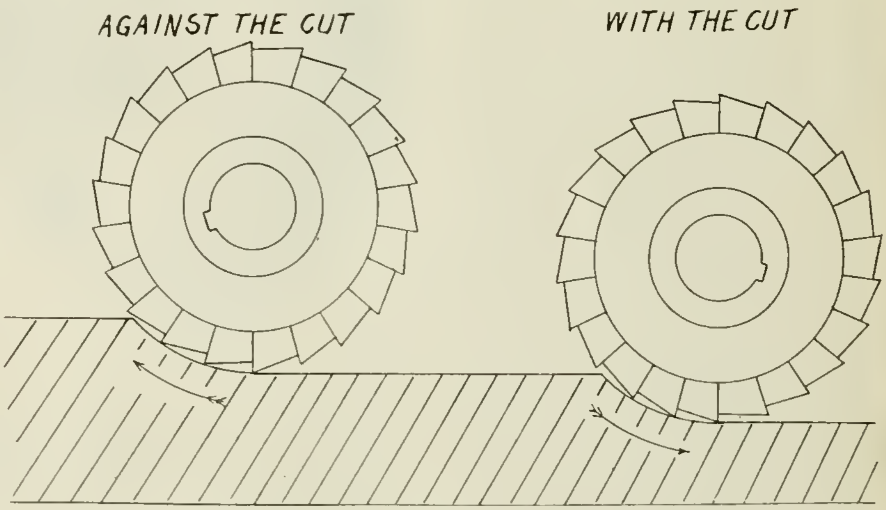

FIG. 71.

on the side with the cut. This fact is responsible for more than fifty per cent. of broken teeth in end mills. Set up the work so that the cutter will remove about twice as much from the side that is feeding against the cut as it will from the side that is with the cut. Also be careful in starting the cut, especially if starting to cut against a square shoulder or the square corner will run in between two teeth and rip a few of them out of the cutter before the damage can be prevented.

DOESN'T BELIEVE IN SAVING TIME.

By N. G. Near.

BOILER factory owners still exist who think they have sound arguments against good time-saving devices. They believe in the old idea—plenty of "elbow grease" as they called it. They think it laziness to permit the brain to do the work through coal and machinery.

I met a friend salesman the other day who told me about an argument he had with such an owner of a boiler factory. He had tried to sell the owner an up-to-date, time-saving machine, but the owner said, "If we used every time-saving device in the world in this factory we wouldn't have anything more to do." Although it is usually fatal for a salesman to be sarcastic with a prospective buyer, this friend of mine said, "Your're right. Henry Ford believes in using as much time-saving machinery as possible in his automobile factory, and that is why he hasn't anything to do nowadays."

It's a fact that some so-called time-saving machines are actually time-losers and they should be carefully weeded out. Again, the time-saving machine may be a time-saver only where it can do jobs over and over, and where it can be kept everlastingly at it. In many instances, holes can be drilled in certain pieces by hand more quickly and more economically than by machinery, and such machinery may be the so-termed "time-saving" variety.

If TIME was MONEY in Ben Franklin's day, doesn't it seem reasonable that time is worth MORE money now?

SETTING A LATHE IN POSITION

By N. E.

UNDUE haste in the setting of machinery is often the cause of subsequent trouble in its operation, much of which may eventually be laid upon the shoulders of the man working it, while in reality it is the machine itself that is responsible for the inefficiency. Neglect in paying sufficient attention to the primary essentials when installing machinery often demonstrates the truth of the saying: "More haste, less speed." Like everything else of lasting value, from the formation of character to the erection of a large building, the nature and permanency of the foundation is the all-important factor. Unless a good foundation is provided for the lathe, it is quite unreasonable to expect that satisfactory work will be produced. Undoubtedly, the chief consideration in the placing of an engine lathe should be the entire elimination of structural stress when setting in position. The legs of a lathe are not alone for the purpose of elevating the mechanism to a convenient working distance from the floor, but they must also be the means of maintaining the bed in its proper alignment; and this is only possible by the relative distribution of weight between the various supports. To attain this, it is necessary that the floor (preferably a special foundation) be previously prepared to receive the machine. A lathe that is not properly leveled cannot be depended upon to perform accurate work. No lathe is so rigid in the bed but that it will develop a "spring" when resting on uneven supports. Spring, no matter how moderate, is detrimental to the accomplishment of good work; irregularity in boring, facing or turning, may result, and chattering may also be one of the faults.

When leveling up a lathe, a fairly sensitive level should be used; one that will respond to the slightest variation from a set position. Thin wedges may be used to attain the objective, but it is more reliable to use suitable liners under the feet that will furnish a wider support than is possible with the wedge, as the sharp edges of the foot of the leg will in time cut into the wedge, thus allowing that corner to sag, and consequently destroying the original setting of the machine. With proper assurance that a lathe has been properly leveled upon its foundation, any faults that may subsequently arise can readily be traced to other causes.

MISTAKES THROUGH VERBAL INSTRUCTIONS

By B. S.

WHO must take the responsibility when errors occur through the misunderstanding of verbal instructions? The inability of any two minds to think exactly alike is often the cause of varying degrees of error in the accomplishment of certain tasks, if there is nothing tangible to verify the orders previously given. In many lines of work, slight divergence from accepted practice matters little in the final achievement, but in other lines of activity it is essential that specific instructions be adhered to, in order that the final result be in keeping with the original intention. In the case of a foreman issuing instructions to a workman regarding the construction of a certain piece of mechanism, it sometimes happens that insufficient details are given the workman for the thorough knowledge of the task before him. The foreman undoubtedly, has given the question much thought before it is submitted to the workman, and when this is done, the instructions are issued from the viewpoint of the foreman who has previously studied the various phases of the subject. The workman, not being a mind reader, thinks he has understood the orders given and proceeds to perform the work, based on the meaning he has taken from the instructions given, with the result that the operation is not accomplished as the foreman had intended.

A case in point was that of a toolmaker receiving instruction to make a forming die to accomplish certain operations. A few brief verbal suggestions, outlining the method of precedure, were given by the foreman, and the workman proceeded to construct the tool according to the understanding he had of the chief's remarks. The die was completed and worked satisfactorily, but the ideas of the workman had varied from those of the foreman to such an extent that the latter was not convinced but that his way would have given still better results.

On another and later occasion, the same shop was confronted with a more complicated problem, that of a stamped piece for which dies had to be constructed. Considerable thought had been given on the part of the superintendent and foreman as to the method of designing the tools, but nothing definite was arrived at when the work was handed to the tool maker with a few brief verbal suggestions as to the purpose of the piece and the method of producing same. In some respects, the workman was given free scope as to the construction of the die, and commenced operations based on his own particular ideas as to what was desired. It chanced, however, that after considerable time and labor had been put upon the tools, the superintendent happened around and told the foreman that the work was not being done as intended, and a general mix-up immediately followed; the outcome of which was an all-round discussion, as to the correct method of construction. There at once arose the question as to who should shoulder the responsibility, as it was not clear just what the original instructions had been. However, after thrashing out the subject from various angles, sketches were developed from the different suggestions that provided a foundation for the construction of the tools, and also indisputable evidence as to workman's instructions.

Definite information, either in the form of sketches or writing, should be issued for the guidance of the workman, where the reasoning factor of the human element is a feature of production. By strict adherence to this rule, better protection is provided for both the foreman and the workman, and will often avoid many of the troubles and misunderstandings common to job shop and special manufacturing practice.

It is a common observation by plumbers that the pipes carrying the hot water from the boiler to the kitchen and bathroom burst from freezing far more frequently than the pipes carrying the cold water. Experiments have been made with glass tubes, the practical conditions being simulated as nearly as possible. The results confirm the above observation, and show that the occluded air in tap water is responsible for the delay or absence of bursting of the pipes, says F. C. Brown in the *Physical Review*.

Development of Wood and Steel Shipbuilding in Canada

By C. T. R.

In addition to the widespread requisitioning of vessels for transportation purposes by the Allies, the war attendant and normal merchant ship losses and the many months' almost complete cessation of new construction on the part of the latter, the merchant marine of the world has had the misfortune to become to a large extent the target for enemy submarine activity. All nations have suffered in this respect, hence the almost feverish anxiety being displayed by shipping interests to have the losses made good at the earliest possible moment.

UPPER LAKES S.S. "WESTMOUNT" LAUNCHED

THE bulk freighter Westmount, which has been built to the order of the Montreal Transportation Co., by the Collingwood Shipbuilding Co., Collingwood, Ont., was successfully launched on April 5, Mrs. L. L. Henderson, wife of the president of the owners company, christening the vessel. The "Westmount" is one of the largest vessels yet constructed in Canada, and is of the single-deck type which has been evolved to meet the conditions prevailing on the Great Lakes of North America in regard to the transportation of bulk cargoes of coal, ore and grain. Her leading particulars are: Length over all, 550 feet 8 in.; length B. P. 537 ft.; breadth moulded, 58 ft.; depth moulded, 31 ft.; load deadweight, 11,000 tons; load draught to suit canals, 19 ft. 6 in.

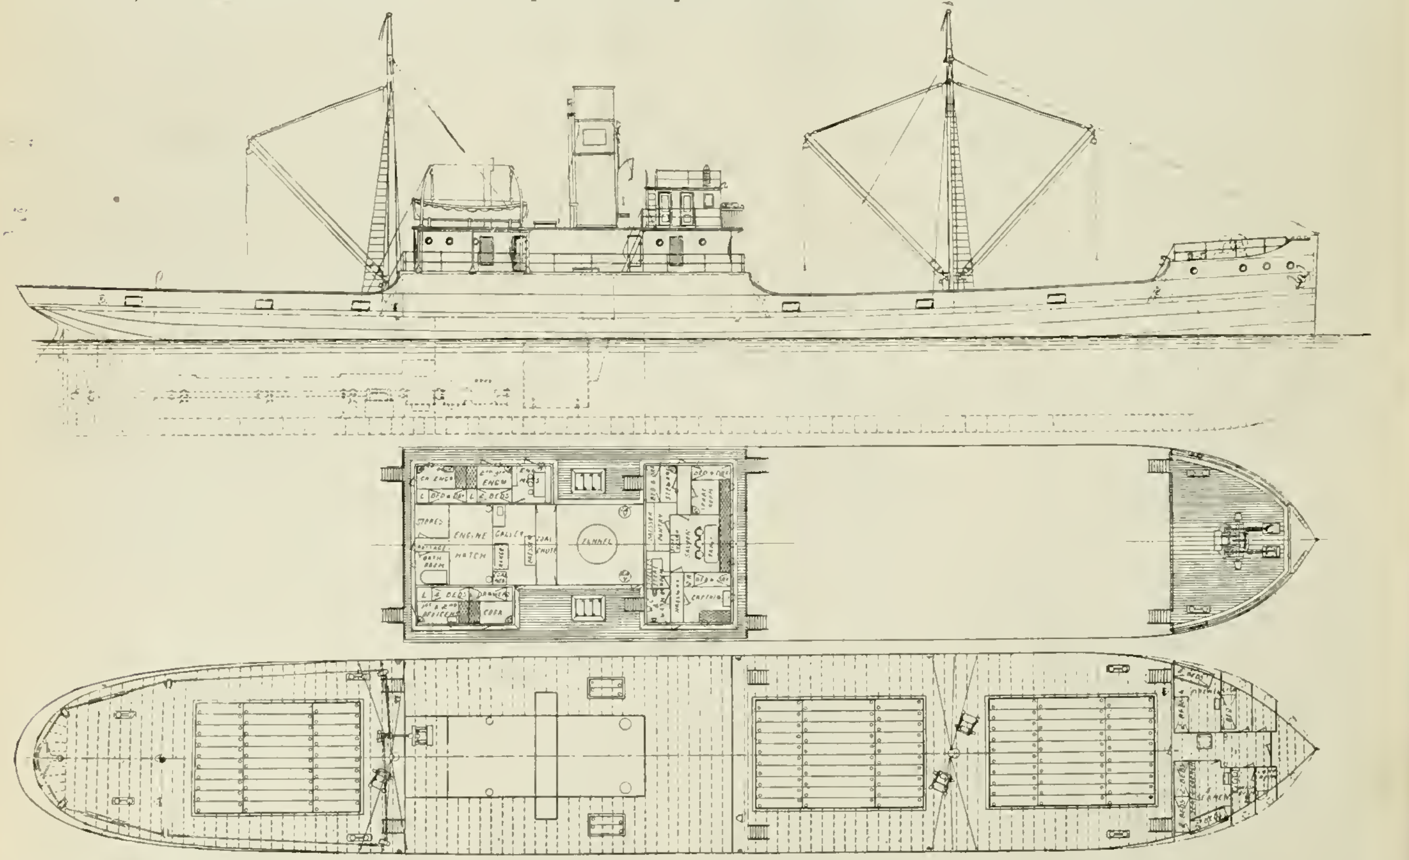
Loading and Unloading Provision

The vessel, in common with the other ships of her class, embodies a number of features introduced to facilitate loading and unloading operations, the short season for navigation on the lakes making quick despatch in port a matter of the utmost importance. No loading or discharging appliances are provided on board, these operations being accomplished by the shore plant. There are 16 cargo hatchways, each having a width of 38 ft. and a length of 9 ft. The hatchways are spaced 24 ft. apart centre to centre to suit the standard spacing of the loading and unloading devices on shore. Between the hatchways, strong arch girders or web frames, extend right round the sections. By the adoption of these girders stanchions are dispensed with and the holds left unobstructed, a necessary feature where coal and ore cargoes are unloaded by clam-shell buckets, as is the case on the Great Lakes. For the same reason there are no deckhouses, spars or other obstructions for the length of the cargo holds.

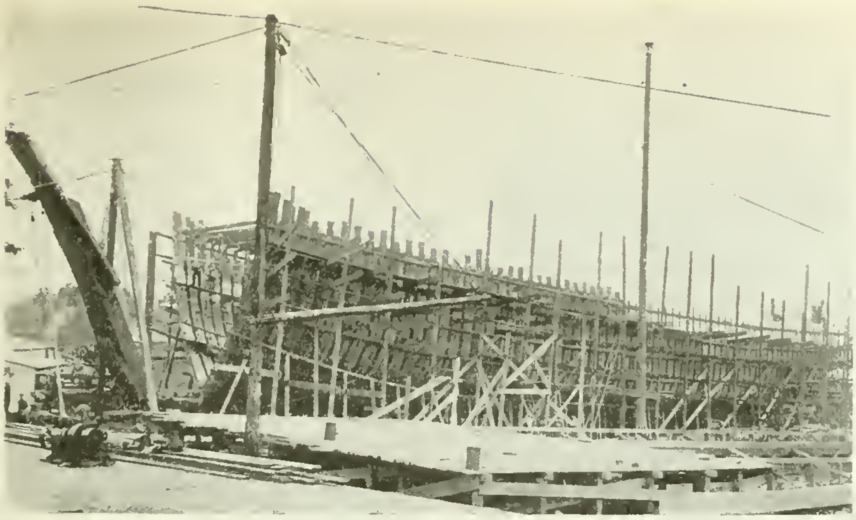
The ordinary transverse bottom and side frames are of channel sections and are spaced 3 ft. apart. The double bottom, which is 5 ft. deep, extends for the full length betwen the peak bulkheads. Side tanks of the same width extend on each side up to the level of the main deck stringer, and thus form a double skin to a height well above the deep load line. The side tanks provide large additional capacity for water ballast, while their inner plating transforms the hold into a compartment of hopper form section, eminently suitable for mechanical unloading operations.

The tank top plating, which carries the weight of the cargo, is supported by the centre girder and by four continuous longitudinal girders on each side of the centre line. Intercostal deep floor plates are fitted in the transverse direction at every second frame, i.e., 6 ft. apart, there being a deep floor at each arch girder and one between. There are two collision bulkheads forward, the space between forming a deep tank.

The cargo hold is divided by screen bulkheads into six compartments and the double bottom by four watertight divisions into five compartments for water ballast. The remaining bulkheads are a cross bunker screen bulkhead, a screen bulkhead between the engines and boilers, and a watertight after peak bulkhead. The upper deck stringer and plating between the hatch



STEEL OCEAN-GOING FREIGHTER BUILDING BY NOVA SCOTIA STEEL & COAL CO., NEW GLASGOW, N.S.



AUXILIARY POWER SCHOONER "MARGARET HANEY" ON THE STOCKS.

and ship's sides are supported by longitudinal channel girders instead of transverse beams. This arrangement is a new feature in a vessel framed on the transverse system, and has the advantage of introducing additional longitudinal strength at a very desirable part.

A short forecastle is fitted above the upper deck right forward. On the port side under the forecastle deck are arranged cabins for the first and second officers, the quartermasters, and watchmen. In a corresponding position on the starboard side are the owner's staterooms. On the forecastle deck above is situated a large steel deck-house containing an observation room and the captain's quarters. The top of this house forms the navigating bridge, upon which stands the wheelhouse.

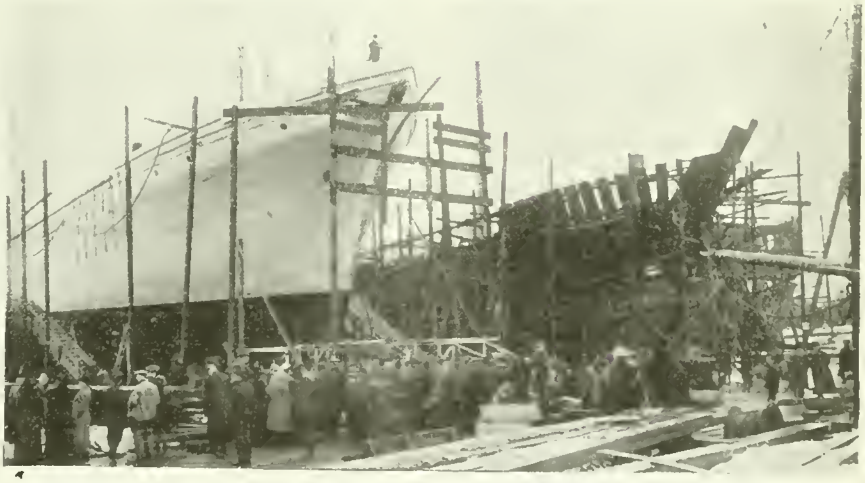
The accommodation provided at the after end of the ship is arranged in a large steel house surrounding the engine and boiler casing. Here are placed the engineers' quarters, galley, dining-rooms for the owner, officers, and crew, respectively, and herths for various members of the crew. The firemen's accommodation is situated on the main deck at the starboard side just abaft the engine-room casing.

Ship Deck Machinery

A powerful steam windlass, of the Emerson-Walker quick-warping direct grip type, is located on the upper deck forward under the forecastle. The cables are 2¼ in. in diameter, each being attached to a "Britannic" stockless anchor of 8,000-lb. weight. The anchors are stowed in suitably shaped pockets, so that they may not foul lock gates or other obstacles when the vessel is navigating narrow waterways.

The main and emergency steam steering engines are situated right aft on the main deck. Both gears consist of a 9 in. by 9 in. steam engine supplied by the American Engineering Co., of Philadelphia, which actuates the rudder directly through a toothed quadrant connected to the rudder stock. This gear is controlled by wires led from the steering wheel in the pilot-house or that on top of same, The emergency gear is always under steam, and can be put into operation in a few seconds by means of a crank on the bridge steering standard, which at the same time throws out of action the main gear.

The deck winches, which number six in all, have been supplied by the Chase Machine Co., of Cleveland. Four of these are 8 in. by 10 in. single-drum mooring units, and are placed two at each end of the row of hatchways. The drums of the mooring winches are arranged in an athwartship direction, fairleads of special design being provided at the ship's side to lead the mooring ropes. Another 8 in. by 10 in. single-drum winch is located in the windlass room forward, while an 8 in. by 10 in. winch, having two drums, is situated on the upper deck aft. One drum of the after winch is intended to take the 3½ in. mooring hawsers, while the other takes the 4½ in. wire hawser which is attached to the stern anchor of 4,000 lbs. weight. The latter, which is also of the "Britannic" stockless type, is stowed on an inclined platform, so that it can be instantly lowered in case of emergency.



AUXILIARY POWER SCHOONER ON LEFT, JUST PREVIOUS TO LAUNCHING.

AUXILIARY POWER SCHOONER "MARGARET HANEY" BEING TOWED TO BUILDERS' WHARF AFTER LAUNCHING

AUXILIARY POWER SCHOONER "MARGARET HANEY" TAKING THE WATER.

General Equipment

The boat outfit consists of two 22-ft. metallic lifeboats and one 18-ft. gasoline launch, for use in harbor, capable of attaining a speed of 8 miles an hour. All the boats are placed aft at the level of the deckhouse top, and are attached to davits and equipped with Huff's releasing hooks.

The vessel has two steel pole masts, one forward and one aft, for signalling purposes and to carry the running lights. Awnings are fitted over the forecastle deck and the pilot-house and at the sides of the after deck-house. Draught gauges are provided at each end of the ship, so that the draught forward and aft may be read in disturbed water or at night.

The ship is lighted throughout by electricity, the total number of lights being about 200. For providing the necessary current there are two electric generators, each having a capacity of about 10 kilowatts. The generators are situated on a flat at the after end of the main engine room. An electric indicator is placed in the pilot-house to show whether all the running lights are in order.

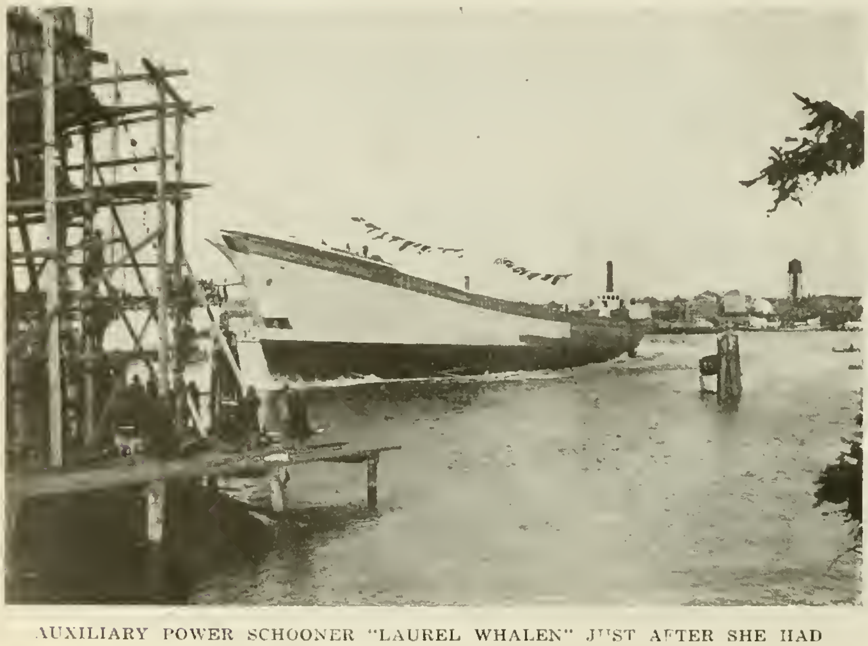
Propelling Machinery

The propelling machinery, which has also been constructed by the Collingwood Shipbuilding Co., is located at the after end of the vessel. Steam is generated by three single-ended cylindrical boilers of the Scotch marine type, each having a diameter of 13 ft. and a length of 11 ft. The boilers are designed for a working pressure of 185 lbs. per sq. in. and are provided with Howden's system of forced draught. From the boilers the steam passes to a single set of triple expansion reciprocating engines having cylinders 24, 40 and 66 in. diameter respectively, by 42 in. stroke. The engines are capable of developing about 2,400 I.H.P. which will drive the ship at a speed of about 13 miles per hour when loaded, and 15 miles per hour when light.

The auxiliary machinery includes one centrifugal and two duplex ballast pumps, one sanitary pump and one deck pump, one duplex main feed pump and one duplex auxiliary feed and fire pump. The air, circulating, and bilge pumps are direct driven from the main engines. In addition to the steam pumps, hand bilge and fire pumps are provided both forward and aft.

The steamer will be sailed by Capt. S. Hill with J. Norris as chief engineer .

AUXILIARY POWER SCHOONER "MARGARET HANEY" READY FOR SEA.



AUXILIARY POWER SCHOONER "LAUREL WHALEN" JUST AFTER SHE HAD LEFT THE WAYS.

AUXILIARY POWERED SCHOONER "LAUREL WHALEN" LAUNCHED

GAILY bedecked, and in the presence of several thousand spectators, the auxiliary powered schooner Laurel Whalen was launched from the Cameron Genoa Mills Shipbuilders' yard, on the afternoon of March 24. Miss Marjorie L. Brewster, the young daughter of Hon. H. C. Brewster, Premier of British Columbia, although only eleven years of age, carried out her role as sponsor with charming grace, and as the vessel started, almost imperceptibly at first, on the downward course the little lady sent the beribboned bottle of champagne crashing against the bow and the Laurel Whalen officially received the name by which she will soon be known in distant ports of the world. In her arms Miss Brewster caried an immense bouquet of American Beauty roses and after the ceremony she was the recipient of a handsome present.

With the launching of the Laurel Whalen there are now four of the fleet of ten vessels ordered by the Canada West Coast Navigation Company afloat, their names being as follows in the order of their launching: Mabel Brown, Margaret Haney, Geraldine Wolvin and Laurel Whalen. The next boat to be launched will be the Jessie Norcross, named after the wife of J. W. Norcross, vice-president and general manager, Canada Steamship Lines. The vessel is building at the Wallace Shipyards, North Vancouver. There remain now on the ways of the local shipyard two more vessels, of the same class as the Margaret Haney and the Laurel Whalen, and work on these two ships will be carried on with all dispatch. The next boat to be launched will be the Esquimalt. The fourth schooner has not yet been named.

Prominent People Present

On the launching stage Premier Brewster was accompanied by other members of the Executive Council, while representatives of every public department and of the business community were present, including civic officers, railway representatives, naval officers, municipal officers, shipping and insurance representatives, the clergy, boards of trade, clubs, legal firms and others.

All four of the schooners now afloat have been chartered to the Canadian Trading Co. The Mabel Brown will load for Sydney, the Margaret Haney for Calcutta, the Geraldine Wolvin for Melbourne and the Laurel Whalen for South Africa.

TRIAL TRIP OF AUXILIARY POWERED SCHOONER "MARGARET HANEY"

WITH a number of invited guests aboard, the auxiliary schooner Margaret Haney spent the greater part of the day of April 5 in a cruise which extended from Victoria harbor out to the eastward as far as Trial Island, and following a semi-circular route, returning by way of Port Angeles, the vessel behaving splendidly throughout the entire trip. A few days later she left for Vancouver to take on a full cargo of lumber from the Rat Portage Lumber Co. mill for delivery at Bombay, India.

Capt. Whitely piloted the Haney on her trial Capt. G. S. Laoraik representing the owners, while included in the passenger list were H. W. Brown, manager of the Canada West Coast Navigation Co., the owners; J. O. Cameron and D. O. Cameron, of the Cameron Lumber Co., who were the first to undertake the building of ships in Victoria; Harry McDevitt of the Empire Lumber Co.; W. H. Bullock-Webster of the legal firm of Bullock-Webster & Bass; S. Baxter, Provincial Boiler Inspector; Geo. Kirkendale, shipping master of Victoria; T. G. Mitchell, Lloyd's surveyor for British Columbia; D. Stevens; Clarence Carter, of the Carter Electric Co.; R. Dowswell, R. C. Ross, W. Cairnes Harper, E. Rochon, E. W. Hume and others.

Makes Good Speed

During the trials, the Margaret Haney made, with sail and power combined, and a breeze of about 3 Beaufort Scale, an average of ten knots per hour. Unfortunately, however, the wind was not of sufficient duration and force to warrant a satisfactory trial with sail power alone, but the management and the experts on board expressed themselves as more than satisfied with the results attained. Weather conditions were ideal for holding the trial, except for the lack of wind, and upon their return to port everybody declared that a most enjoyable and profitable day had been spent, having learnt something about the construction and the working of the locally-built ship.

The auxiliary powered vessels being built on the Pacific Coast are all of the Margaret Haney type, and are capable of being handled by eighteen men, including captain, two mates, three engineers, one donkeyman, two apprentices, seven seamen, cabin boy and cook. The officers' quarters are located under the poop deck and are very conveniently laid out, while the quarters for the crew are situated forward.

Oil Fuel Provision

G. Kingsland, superintending engineer for the company, laid out the engine room, tank, fuel and water arrangements and the engines were installed in the Margaret Haney under his instructions by A. T. Blythe. The fuel used is crude oil. The main fuel pumps draw fuel from any one of the six main fuel tanks and discharge into the service tanks; they can also be used for trimming purposes by discharging back into any one of the six tanks. The fuel pumps are in duplicate so that in case of any accident where one goes wrong the other can be used. The system of filters on the main fuel line is so arranged that either of the filters may be taken out and cleaned without in any way hindering the flow of fuel to the main engines.

Propelling and Auxiliary Machinery

All the auxiliary engines on the boat, which include windlass, four winches, one fire pump, bilge pump and two fuel pumps, can be run on either steam or compressed air. The steam is furnished by a donkey boiler located under the fo'castle head, and the air by two compressors on the main engines and one auxiliary compressor driven from the electric light plant. The main engines consist of two 160 horse power Bolinder engines, from Stockholm, Sweden. The horse power is developed at 225 revolutions per minute, giving the ship a speed of approximately 8 knots under power alone.

The engines are of the two-cycle type, as is most common among semi-Deisel engines. A direct reversible mechanism consisting of a one-way clutch allows the propeller to turn free when the vessel is under sail. This means that practically all drag from the propellers will be eliminated as when the ship attains a speed of over 2 knots, the propellers will turn of their own accord. This clutch is manipulated by compressed air, and the rams used for the purpose were built in Vancouver.

Reversing Gear

The reversing gear is very simple, being controlled by one lever which automatically stops the injection of fuel from the fuel pumps and, as the engine comes to rest, injects a single jet of fuel into the cylinder as the piston is on the up-stroke. The pressure caused by this explosion brings the piston to rest and starts it on the down stroke before it reaches top centre.

The fuel consumption of the engines when developing their rated horse power of 160, is a little over eleven gallons per hour, and as the fuel tanks have a capacity of 30,000 gallons, it will be seen that the vessels have a large cruising area.

Electric light is furnished throughout the ship by a four kilowatt Canadian Westinghouse generator which is driven by an eight horse power Bolinder engine of a similar type to the main engines. This engine also drives an auxiliary air compressor which may be used when the main engines are at rest to furnish compressed air for operating either the bilge or the main fuel pumps.

Ventilation in the engine room is furnished by two skylights, located at the after end, and two ventilators, one on each side. The circulation of air from these keeps the engine room at a moderate temperature, and it is not expected that it will become excessively hot even when the ship is in a tropical climate.

Victoria, B.C.—A survey has been made of the G.T.R. Steamer Prince Rupert which is now in dry dock at Yarrows Ltd. The damage is extensive and repairs will take about two months to complete.

SHIPBUILDING PLANT FOR TORONTO

We are in a position to advise that steps will be taken very shortly towards the establishment of a large shipbuilding plant on Ashbridge's Bay, Toronto, the executive personnel of which we meantime may not disclose. It may, however, be stated that the men behind the project are not only well and favorably known as residents of the Queen City, but as successful business men in enterprises whose scope finds an outlet both there and in a Dominion-wide sense.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

COMBINED STEAM TURBINE AND CENTRIFUGAL BOILER FEED PUMP

THE tendency towards displacement of the reciprocating boiler feed pump by the centrifugal pump furnishes a good example of the necessity resting upon manufacturers of machinery for sustained technical development. Since it must handle a comparatively small amount of water against a relatively great head, the centrifugal boiler feeder should be fitted with small diameter impellers running at high speed. It is therefore well adapted for steam turbine drive. Fig. 1 shows an early steam turbine-driven boiler feeder built in 1910 by the De Laval Steam Turbine Co. The two-stage pump has a capacity of 1,600 gals. per minute against 700 ft. head at 2,800 r.p.m., and upon test gave an efficiency of 60 per cent. The pump is entirely independent of the turbine, a coupling being interposed between the pump shaft and the turbine shaft, and it could therefore have been driven just as well by electric motor or by rope or belt as by a steam turbine.

The unit, however, realized the advantages peculiar to the centrifugal boiler feeder, viz., reliable and uninterrupted service with little, and often unskilled attention, absence of pulsation, shock, water hammer, vibration, or over pressure in pipe lines, elimination of relief valves, suitability for use with automatic boiler feed regulators acting independently at each boiler and with feed water meters, close governing, either by speed governors or by pressure governors, freedom from injury by overloading, lightness and compactness, accessibility, elimination of valves, packings, sliding surfaces and air chambers, small upkeep and attendance expense due to simplicity and few wearing parts, lower cost of maintenance of piping system, small consumption of oil, efficiency, and in the turbine-driven type, ability to use superheated steam or to run upon either high or low pressure steam, oil-free exhaust, and independence of the main units.

A still further development in the direction of compactness and simplicity is shown by Figs. 4 and 5, illustrating a 3,000 horse-power, two-stage centrifugal boiler feeder combined in one casing and on one shaft with a velocity-stage steam turbine. This unit, which also has been developed by the De Laval Steam Turbine Co., weighs, it is claimed, about one-tenth as much as a duplex reciprocating pump of the same delivery and occupies only about one-eighth as much floor space and one-fifteenth as much cubical space.

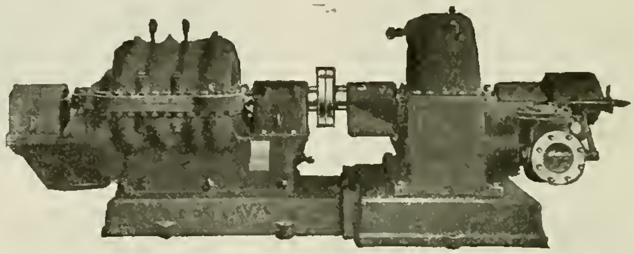


FIG. 1. DE LAVAL CENTRIFUGAL BOILER FEED PUMP COUPLED TO INDEPENDENT TURBINE.

The pump end contains two single-suction impellers cast from a special bronze and carefully finished to exact contours. Two impellers are used for pressures up to 200 lbs. per sq. in., and three impellers for higher pressures. Single-stage boiler feed pumps have been built, but two or three stages are preferable because of the much longer life of the impellers at slower speeds. Each impeller discharges into a volute chamber by means of which the velocity in the water as it leaves the impeller is converted into pressure before the water is led to the eye of the succeeding impeller. This means of energy conversion is claimed to be superior to the use of diffusion rings as it is efficient over a wider range of delivery, and more important still, does not involve the use of small and sharp parts like diffusion blades, which are subject to rapid erosion.

The pump is hydraulically balanced and only one pair of labyrinth rings surrounding the suction opening is required for each impeller except the last, which has two sets of rings. The whole back of the impeller is subjected to a pressure equal to that existing at the periphery of the impeller, the same pressure acting on the front of the impeller, except for the area of the circle enclosed by the labyrinth ring about the suction opening. The last impeller, that is the one from which the water is finally discharged, is equipped with two sets of wearing rings, one on the suction side and one on the reverse side of the web. As some water from the discharge of this impeller will leak between the wearing rings into the space back of the web, this impeller would be equally as unbalanced as the other impellers in the pump if there were no escape for the leakage water. To provide for diminishing the pressure in this balancing space as much as may be required to

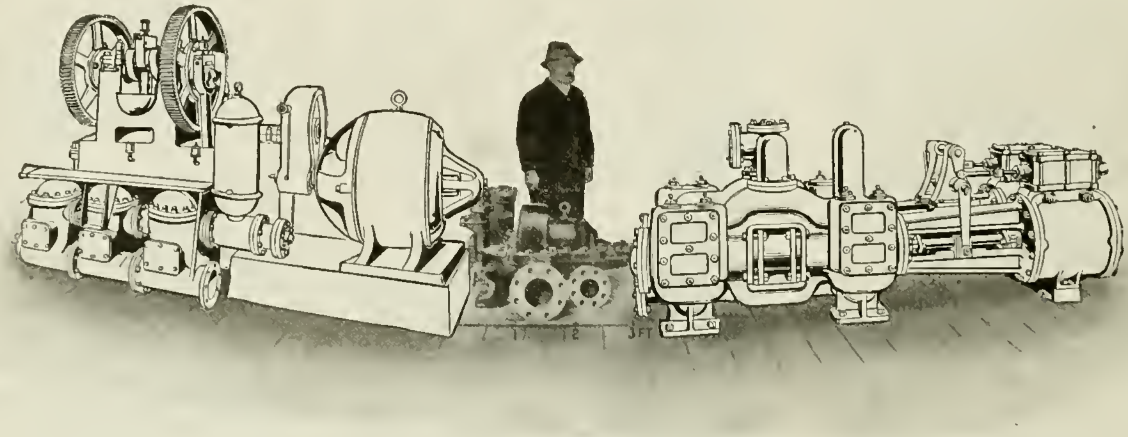

FIG. 2. COMPARATIVE CAPACITY DIAGRAM SHOWING STEAM TURBINE-DRIVEN BOILER FEED PUMP, DUPLEX STEAM PUMP, AND TRIPLEX MOTOR-DRIVEN PUMP.

bring the whole series of impellers into balance, a leakage outlet is provided from which water can be conducted back to the suction of the first impeller.

The outlet leakage takes place between two collars, one attached to the casing and the other carried on the shaft. When the shaft moves towards the discharge end of the pump this escape is closed off and the pressure builds up in the balancing chamber. If the shaft, on the other hand, moves toward the suction, this escape passage is opened wider, allowing the pressure in the balancing chamber to fall and at the same time the inleakage between the labyrinth wearing rings is decreased. By this means direct and positive balancing within very close limits is secured with leakage of but a small amount of water. The so-called natural balancing secured by the use of double suction impellers in a multi-stage pump is in comparison uncertain and imperfect, besides involving an extra long shaft, heavier impellers, and two pairs of wearing rings to each impeller.

The labyrinth wearing rings are readily renewable, the stationary ring of each pair being held in seat in the casing and the rotating ring being screwed upon the impeller. The reduction of leakage secured by the use of intermeshing labyrinth rings is highly important for securing high efficiency in pumps of comparatively small delivery. With the labyrinth type of ring the leakage path is so tortuous that very little water escapes even at high heads, although ample clearance is provided to take up expansion and contraction due to changes in temperature.

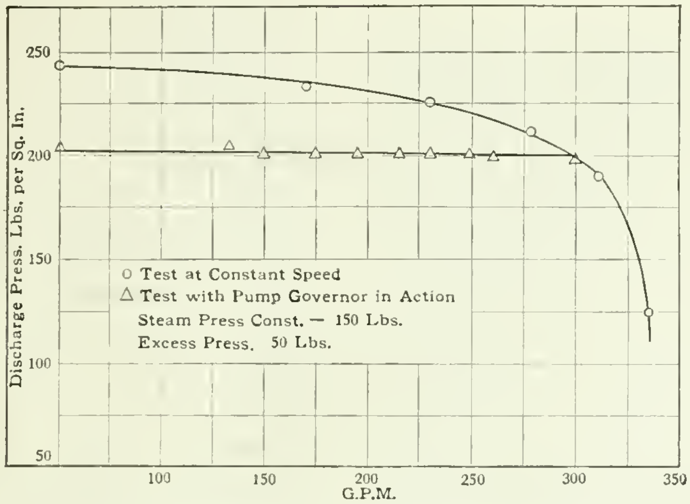

FIG. 3. HEAD DELIVERY CHARACTERISTIC OF DE LAVAL TURBINE-DRIVEN BOILER FEED PUMP UNDER CONTROL OF SPEED AND PRESSURE GOVERNORS RESPECTIVELY.

The suction end of the pump is adjacent to the turbine, and the shaft packing between the turbine and pump chambers is hence subjected to turbine exhaust pressure on one side and the suction pressure on the other. A simple packing is therefore sufficient, and in any case, any small leakage of steam in one direction or of water in the other does no harm. As the leakage space adjacent to the balancing chamber at the discharge end of the pump is connected back to the pump suction, the packing about the shaft is subjected only to suction pressure. Aside from the intermediate packing already mentioned, there is only one steam packing, which is subjected to exhaust pressure.

The steam end of the unit consists of a velocity- stage turbine with either two or three rows of moving buckets, according to the steam economy desired. The nozzles can be proportioned for either high pressure steam exhausting to feed heater or to condenser or for low pressure steam exhausting to condenser, or the unit can be made interchangeable, thus permitting of a great degree of flexibility in plant design. Where the exhaust steam from the boiler feeder is consumed in heating feed water, the thermal efficiency of the turbine- driven boiler feeds is greater than that of a boiler feeder driven by electric motor, or even than that of the main unit itself.

The unit is in some instances fitted with a speed governor mounted upon the end of the shaft, and when running at constant speed, the head varies with the delivery, as shown by the curved characteristic in the accompanying chart. As will be seen, the rise in pressure at reduced capacity is not excessive. Ordinarily, however, a pump governor controlled by the pressure at some point in the feed line near the boilers is employed to control the speed, giving a practically uniform pressure at all deliveries, as shown by the lower and straight line in the chart. In case of failure of the pressure governor to operate, the control of the unit is automatically taken over by the speed governor.

However, to provide against any possibility of racing, an emergency governor is also fitted. This consists of a pin contained within a hole bored diametrically through the shaft. This pin is held by a spring from flying out under the influence of centrifugal force. When the speed reaches a certain point, the spring is compressed so that the pin strikes a trip, releasing another spring by which the governor valve is closed at once and completely. Racing and excessive over-pressure are therefore impossible. The normal speeds of these pumps vary from 1,800 to 3,500 r.p.m., according to pressure and capacity, and due to the heavy shafts employed are far below the critical speeds.

The bearings are of the straight, split ring-oiled type, and like other parts subject to wear, such as the pump impellers, turbine rotor labyrinth rings, and governor valves, are built to a limit-gauge basis, so that they are all interchangeable. The entire rotating members and all wearing parts, with the exception of the governor valve, are accessible for inspection or removal upon lifting the casing cover and taking off the bearing caps,

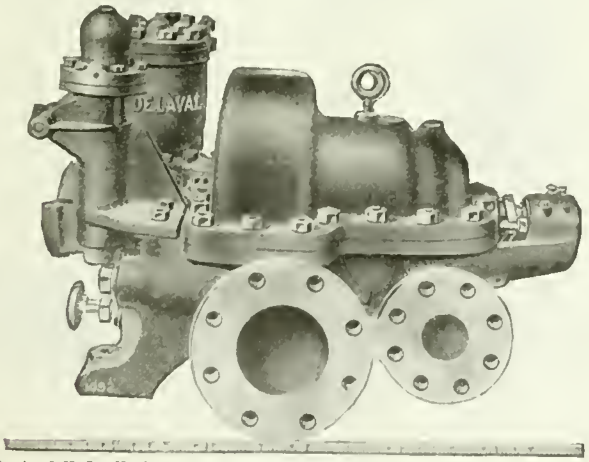

FIG. 4. DE LAVAL COMBINED TURBINE-DRIVEN BOILER FEED PUMP. CAPACITY 3,000 BOILER-HOUSE POWER.

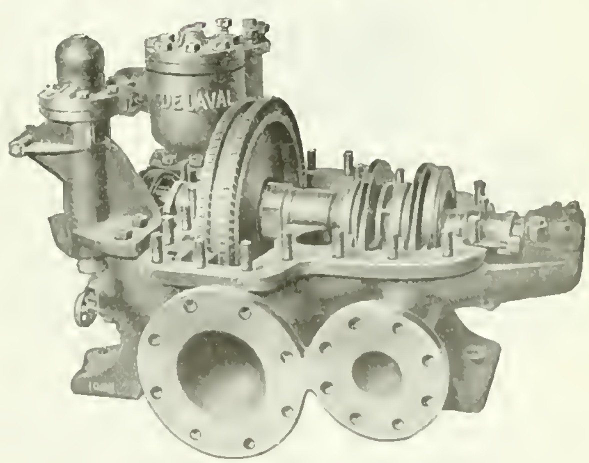

FIG. 5. DE LAVAL COMBINED TURBINE-DRIVEN BOILER FEED PUMP WITH CASING COVER REMOVED.

all of which can be done without breaking steam or water pipe connections.

In specifying the capacity of boiler feeders ,the temperature of the water to be pumped should always be stated, as the capacity is nearly 50 per cent. greater with water at 75 deg. F. than with water at 210 deg. F. For the same reason, capacity and efficiency tests of a pump should be carried out with water at the temperature at which it will be received by the pump when in actual service. The De Laval Steam Turbine Co inform us that they are equipped to make such tests on all pumps that it builds.

TRIPLE PURPOSE RADIAL DRILLS

A NEW triple purpose radial drilling machine has been developed by the American Tool Works Co., Cincinnati, which is so designed that in addition to performing the work of a standard radial machine, will do boring operations efficiently and economically that heretofore could not be handled on a radial drill. This result is accomplished by providing a quadruple gear head affording four distinct speeds, the two lowest forming the heavy tapping and boring range, and the other two speeds being adapted for high-speed drilling and light tapping.

The lower speed range in conjunction with the eight gear box speeds offers, sixteen speeds from 15 to 31 rev. per min. which are obtained through an internal gear drive on the spindle, while the high speed range consists likewise of sixteen speeds which vary from 94 to 500 rev. per min., these latter being obtained through an external gear drive which is so arranged that it is non-interfering with the internal drive. A striking feature of this machine is the manner in which the head mechanism is fully enclosed by a single housing which displaces the numerous gear guards usually employed and contributes greatly to increased safety in handling the machine.

Convenience of handling and simplicity of construction have received more than ordinary consideration. Two traversing hand wheels are fitted, one on each side of the head, and also two spindle racking levers. A conical roller-bearing is interposed between the column and bottom of the sleeve to insure easy swinging, while a radial ball-bearing at the top of the column takes all side thrust from the sleeve. The simplicity of the entire mechanism is evidenced by the fact that only 15 gears are required in the speed changing mechanism to provide for 32 spindle speeds.

In view of the increased field of applications of the machine, the question of material has received more than ordinary consideration. With the exception of a few feed gears, for which manganese bronze is employed, every gear is of steel, the pinions and clashing gears being heat-treated and hardened. All shafts in the head and gear box are made of high-grade crucible steel, while the long vertical and horizontal shafts are made of 45 point carbon special ground stock. Every cylindrical bearing is the machine is renewable, and is bushed with a high-grade of phosphor bronze.

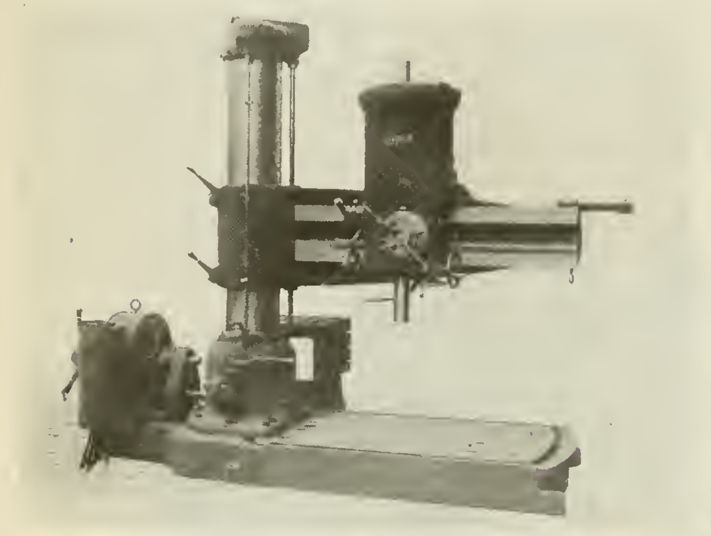
Centralized lubrication is a prominent feature, eliminating all possibility of trouble from overlooking any one point of application. Every oil duct is brought to centralized locations on the head and cap, at which points the oil is introduced. Annular oil chambers are formed on the outside of each bushing, the flow of oil onto the shaft being through a strip of felt inserted in a lengthwise slot in the bushing, this construction insuring a continuous and uniform supply of clean oil to the bearings and preventing waste of oil before it has performed its duty.

Eight feeds are provided in geometrical progression from .005 to .040 in. per revolution of spindle. This mechanism is direct reading and only one dial is required for its operation. The feed mechanism is thoroughly protected against sudden shocks or excessive stress by a friction which forms the connection between the mechanism and the spindle, and acts as a slipping point.

A similar device is incorporated in the elevating mechanism, so that the shock of gear engagement is completely absorbed. Automatic "'knock-outs" on the elevating shaft prevent the arm from travelling beyond pre-arranged points on the column.

The cone and tumbler type of gear box has an automatic silent clutch auxiliary drive which keeps the shafts and gears running while the speed changes are being made, removing most of the shock of engagement. Provision has been made for the use of an arm support when doing heavy boring. The standard motor drives are through gear box, and direct connected.

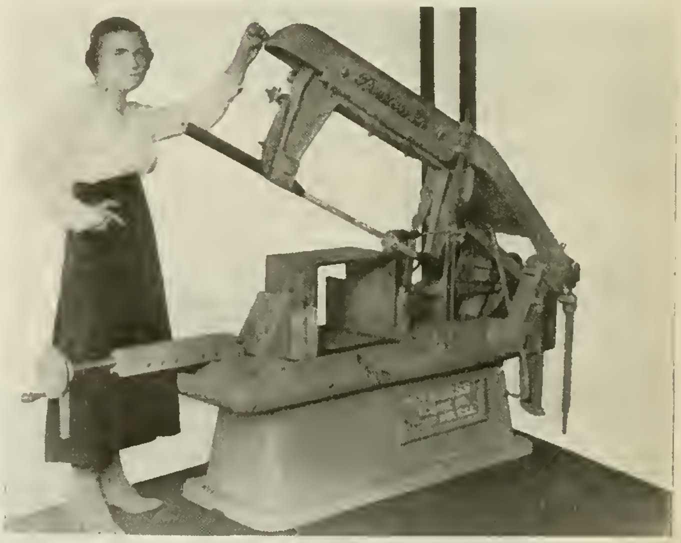
Regular equipment includes plain box table 28 in. square, with a machined side surface 28x14 in. mounted on an extension to the base at side of column, double friction countershaft, and cone pulley drive. No wrenches are required.



TRIPLE PURPOSE RADIAL DRILL

HIGH-SPEED HEAVY DUTY CUTTING-OFF SAW

ABILITY to perform heavy duty work to the full extent of its capacity and at the same time possessing a sensitiveness of operation which adapts it to work of smallest size, characterizes the high-speed cutting-off saw illustrated herewith. This machine is a recently developed design by the Peerless Machine Co., Racine, Wis., the principal feature of the tool being the manner of controlling the saw guide, which is counterbalanced by the four coil springs mounted in such a way that the bearings are relieved of all strain while the tension in the springs acts so as to raise the saw frame upwards.



HIGH-SPEED HEAVY DUTY CUTTING-OFF SAW.

An adjustable spring-controlled feeding mechanism is so arranged that the frame cannot feed down unintentionally. Feeding of the frame down to the work is accomplished by two ratchet dogs which give a uniform feed pressure on the blade throughout the entire cut. The pressure of the feed is controlled by a hand lever which is instantly adjustable, and the mechanism is so connected to the belt shifting lever that the feed does not engage until the belt is about three-quarters on to the tight pulley; this allows the machine to get up full speed and supply a stream of cutting compound to the blade before it comes in contact with the work. Should the machine be inadvertently started while the saw blade is above the work, it will feed down by means of the feeding mechanism until the blade comes in contact with the work, after which the feed is decreased to whatever the blade will cut.

Should the blade break, the frame feeds down to an adjustable stop when it is automatically released and returns to its upper position, the belt being simultaneously returned to the loose pulley .

The saw frame has square ways with provision for taking up wear in the slide. It is driven by a steel crankshaft of the centre crank type. The rear vise jaw swivels to allow for handling mitre work, and the front jaw is of a quick acting type, with handwheel for rapid adjustment and ratchet lever for tightening up.

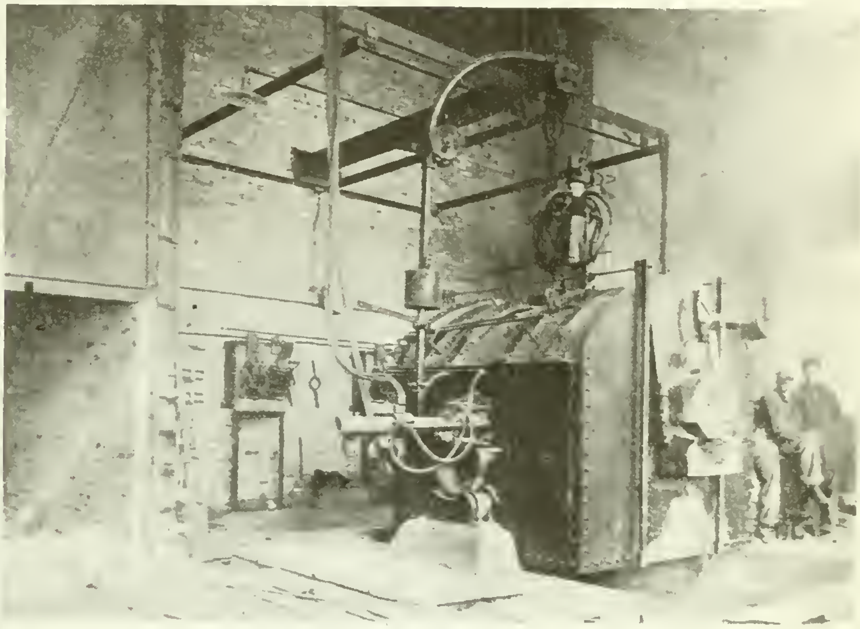
A brass gear pump is located in the cabinet base for supplying cutting compound, and the table is provided with two tee-slots for bolting irregular work, while a deep tray surrounds the tble for catching compound and chips.

The machine illustrated has a capacity of 13x16 in. stock and weighs 1800 lbs. It can also be equipped with direct motor drive and also with 6-speed gear box.

RENNERFELT ELECTRIC ARC FURNACE

DURING the past two and a half years, or since the inception of the shell industry, the utilization of the electric furnace for the production of steel has made rapid and remarkable progress, and the knowledge acquired during this period of activity will, in all probability, open a still wider field for this process of manufacturing steel and other metals on a commercial basis for many domestic requirements.

Electric furnaces are not only finding a place in the foundries of the steel industry, but are proving themselves to be an essential factor in the evolution of this branch of engineering practice. While the principle of all electric furnaces is similar, the method adopted by the different manufacturers of applying electric current for the dissolution of metal provides a means of comparison for the various makes of furnaces. The outstanding features of the Rennerfelt electric arc furnace, illustrated herewith, are the location of the three electrodes. ... electrodes, and this forces the entire radiating arc, by the resolution of forces and electro-magnetic action, down on the bath. The horizontal electrodes are about 15 inches above the bath or slag in some of the larger size furnaces, and the operating distance from tip to tip of the horizontal electrodes is usually from 18 to 22 inches or more. These dimensions give an idea of the size of the flame, which, striking the bath, mushrooms to the side and ends of the furnace. The heat reaching the roof is consequently very indirect, thus favoring low roof-maintenance costs.



"RENNERFELT" ELECTRIC ARC FURNACE INSTALLATION.

On account of the peculiar characteristics of the Rennerfelt arc, it is very steady with hand regulation, and the furnace operation is electrically simplified to a marked degree, by avoiding all automatic electrode regulation, although motors with push button control are contemplated. As only 4 or 6 pounds of Acheson graphite are burned away per ton of cold steel scrap or pig iron, melted and treated, it is evident that the electrode regulation with such a steady arc, made between three points of stability, that is, the tips of three electrodes, is a minimum. Light metal scrap or turnings can be heaped in the furnace with the electrodes touching the charge, and yet before many minutes the free burning arc between the electrode tips has established itself. The majority of these furnaces are operating with basic bottoms; but in the case of a few, where high-class raw material is available at reasonable prices, the acid bottom has been adopted.

The wear of the electrodes seems to depend upon three things—first, the density of the current; second, the cir- ... of the cooling boxes is also made less. Only ⅛-inch clearance is allowed, which is just enough room to compensate for the slight irregularity in the manufacture of what are ordinarily perfectly round electrodes.

Probably the greatest advantage that can be accorded to this type of furnace is its adaptability to the satisfactory dissolution of all kinds of metal, such as copper, bronze, red brass, nickel, aluminum, and such mixtures where zinc does not predominate, or where the percentage is low. The quiet state in which the metal is retained during the melting process is one of the chief reasons why the oxidation and volatilization is kept very low, thus preventing the escape of poisonous gases from copper charges. This may also explain in a measure why the burn-off in ordinary miscellaneous steel scrap is only about 3 per cent. in the Rennerfelt furnaces. These furnaces are being placed on the Canadian market by the firm of Hyde & Sons, 12 Bleury Street, Montreal.

Some Loan.—A Kerry peasant sued another for a loan. "It was a Kathleen Mavourneen loan, yer honor, an Paddy Kane knew it was at the time he gave it to me," said the defendant.

"A Kathleen Mavourneen loan?" said the puzzled judge. "What sort of a loan is that?"

"That's what we call one kind of loan, yer honor, down in our part of the country; it may be for years and it may be forever."

OBJECTIVE OF MUNITIONS SCRAP CONSERVATION

AS a result of the demand for munitions steel, the rolling of rails for either domestic or export purposes has now been at a standstill for many months in each of our two steel mills specially equipped for same. The need of steel rails is only less urgent than that of munitions steel, and just here there exists ample evidence that as shell requirements become less pressing, and cease ultimately, a period of more or less abnormal activity will continue to mark steel plant operation on rail production.

It may readily be taken for granted that the initiation of the big electric steel plant now under construction in Toronto for the Imperial Munitions Board was inspired with the idea of relieving one or both of our rail mills of their munitions steel burden, and while the electric steel plant referred to will not produce from the raw materials —the latter as commonly understood, in another sense, the material from which its product output will be derived, may readily be classed as essentially raw. In a word, our quite enormous tonnage of scrap shell ends, shell crop ends, shell machining turnings and borings, defective billets and forgings are going to be conserved, instead of shipped out of the country as scrap, and will be reproduced in shell billet size and quantity to conform with immediate requirement.

The needs of our railroads become daily more pressing, steel for almost any one of their departments being quite as urgent as that relative to rails. The Imperial Munitions Board is alike in intimate touch with Empire and our own specially national needs, and as we have on former occasions voiced a word of appreciation of their efforts in directing our munitions and shipbuilding industries, it seems fitting that the highly important matter of our railroad maintenance should also be mentioned as coming within the scope of their vision and activities.

THE BIG SHELL SITUATION

AN editorial in our April 19 issue gave very positive indication that 8 ins. and 9.2 ins. high explosive shell manufacture would shortly cease so far as Canadian machining plants were concerned. The capacity of Britain's National Shell Factories to more than meet the needs of our forces in the field with respect to the above named type and size projectile was given as the primary reason the all too rapid depletion of the world's merchant marine from enemy "plunger" activity was nevertheless, in large measure, the deciding factor. The supply of munitions has been fully assured for many months now, and is little likely to suffer diminution; the really crucial stage was passed quite early in the war, comparatively speaking. An equally crucial situation is, however, menacing us—that with respect to food supply and its overseas transportation, therefore, while there is assurance that the guns are being fed, there is much less certainty that those who serve the guns in the field and in the workshop may not be crippled in their effort through not only insufficiency, but positive lack of food.

Admittedly, the decision to eliminate the production of completed 8 ins. and 9.2 ins. high explosive shell in Canada is not relished by the various plants concerned, and not a little activity is being displayed by the different executives with a view to renewal of contracts whose extent will enable existing equipment being conserved until all possibility of its further need for shell making shall have vanished, and its relative usefulness shall have been at least compensated for. Naturally, the Imperial Munitions Board are far from desirous that our big shell making plants should seek to dismantle while the war is not yet won; as a matter of fact we are safe in saying that the Board is fully alive to every phase of the situation as it exists, and is earnestly endeavoring by negotiation and personal effort in the proper quarter to secure such modification of the order relative to the suspension of big shell production, as will involve the minimum of hardship to our metal-working institutions. C. B. Gordon, vice-chairman of the Board is in England in connection with big shell contract renewals, although, of course, not solely, and during the sojourn of the British diplomats on this side of the Atlantic, it can confidently be assumed that the Chairman of the Board, Mr. Flavelle, has taken prompt steps to bring the necessary pressure to bear in that quarter with the like end in view, supplementing Mr. Gordon's efforts.

CANADA'S 1917 BUDGET

IT may be said of our Finance Minister's Budget, brought before the House of Commons, Ottawa, a few days ago, that its substance is nothing more or less than an expansion of the scheme of taxation of war profits, now operative. In another section of this issue a condensed detail is given of its leading provisions.

Considered either apart from or in conjunction with the present war taxes, or an income assessment, there are other taxes which, if made immediately effective, would help to pay our war debts as we go with no other effect than checking public extravagance of which there is so much evidence.

If the tax on automobiles were increased by $10 there would be no burden on anyone who could not well bear it. The amount would be large and could be readily collected. In fact it is a tax which might well be continued after the war and the fund used to the betterment of the national highways. The tax on theatre tickets could well be doubled. There would be no increased cost for collection. The proportions are such that the poorer classes would not be greatly affected. It is a tax which would not be a burden to judge by the crowds attending houses of entertainment. Even if these crowds were decreased there would be no great harm and the public spirit would be curbed to something more appropriate to the time. In addition to the foregoing, there are numerous other commodities in the nature of luxuries which might similarly constitute a means of increasing national funds without affecting, at

INDUSTRIAL NOTABILITIES

WALTER BAKER CHAMP, secretary and treasurer, and a director of the Hamilton Bridge Works Co., Ltd., Hamilton, Ont., was born in that city, March 22, 1874, son of William S. and Sarah Emily Mitchell (Hillman) Champ.

After receiving his education in Hamilton Public Schools, Mr. Champ began his business career with the Hamilton Bridge Works Co. in 1891; was appointed treasurer of the Company 1898; secretary and treasurer, 1905; and has been a director of the Company since 1910.

Mr. Champ is a member of Hamilton Board of Trade and was president thereof

WALTER BAKER CHAMP.

during 1909. He is a member of the Canadian Manufacturers' Association, having been a member of the Executive Council from 1909-1912. Additional administrative activities include, member of Executive, Hamilton Patriotic Association; treasurer, Babies' Dispensary Guild (Incorporated) Hamilton.

On April 17, 1908, he married Jessie Coates, daughter of John Coates, Ottawa. In politics he is Conservative, and in religion, Anglican.

Mr. Champ's clubs are: Hamilton; Hamilton Jockey; Hamilton Golf and Country; Hamilton Thistle Curling (President, 1915-1916), his recreations being golf, tennis and curling.

Mr. Champ resides at 333 Caroline Street South, Hamilton.

The General Market Condition and Tendency

THE industrial situation, while favorable in regard to volume of business, is not so satisfactory in other respects. There is still a shortage of many lines of raw material, and the freight situation is not as it should be. There is still considerable congestion in the railway yards, and as a result deliveries are delayed. The coal situation is also causing considerable uneasiness owing to shortage of supplies and continued high prices. The advance in miners' wages and increase in cost of transportation will result in higher prices for the consumer. The situation in the steel market in the United States is becoming more settled and prices continue to advance. The demand for steel products is steadily increasing in spite of the abnormally high prices, and there is no sign of any decline in either respect; in fact, indications point to further advances and increases in volume of tonnage. The pig-iron situation is unchanged. Domestic iron is still off the market, and quotations therefore are unobtainable. Prices of copper and brass scrap have declined in sympathy with the virgin metal market. Steel and cast iron scrap on the other hand are firm and in good demand. The non-ferrous metal markets are unsettled on account of the uncertainty prevailing as to the requirements of the United States Government and fixing of prices. Copper and spelter are weaker and have declined, but tin is stronger and higher. The machine tool market is fairly active, but deliveries continue slow except on lathes. Prices continue to advance, affecting high-speed drilling machines and millers.

Montreal, Que., April 30, 1917.—Industrial and commercial interests are at present closely watching developments in the United States. That the general situation will experience some change is admitted, but to what extent, the trade here is still in doubt. The easing off in the production of the heavier shells has resulted in the return of some of these plants to pre-war activity, and the domestic efforts of manufacturers are again coming to the fore. Inland marine is becoming more active and shipping interests are preparing for the season's work; river buoys are being rapidly placed in position and within a few weeks summer activity is expected to be resumed. The steel industry continues to hold the center of the stage and is featured by further advances in many lines. Owing to the preparations now going on in the States the general industrial is rather unsettled but without seriously affecting the strong tone of the market.

Pig Iron

While production proceeds at very high pressure, the market itself has had a relatively quiet week respecting the usual advances, but this temporary lull may be followed shortly by further climbing in price quotations. The advance orders on pig iron at all furnaces retain this market in a remarkably firm position and even first half 1918 positions are being largely filled. Prices on Chicago iron have been advanced approximately $2 per ton, but other grades have had a week's rest. The week's advance on composite pig iron is about 30 cents per ton. The local situation is practically unchanged, Canadian iron still being an absent feature in market quotations.

Steel

If such a condition is possible the steel situation is entering another phase of additional activity, that of supplying the requirements of the United States government. This demand is gradually assuming large proportions but it is not definitely known at what price this business is being placed. The delivery of this material will of course require some calculation by the producing mills, owing to the filled up condition of the various branches of the steel industry. While the Canadian situation has experienced no serious effect as yet, there is a pronounced increase in the difficulty in obtaining delivery on certain classes of steel products. The increasing pressure that is being placed upon the mills and the heavy demand for future positions is reflected in the advances that are constantly being quoted for all grades of steel. The inability to fill the requirements of the sheet trade has resulted in sharp advances at different times in the price of sheet bars. The Pittsburgh quotation on sheet bars this week is $85 per ton, an advance on the week of $5 per ton. The enormous call for forging billets has resulted in still higher prices, the most recent advance of $20 per ton raising the current quotation to $110. The Pittsburgh price on wire rods has again been advanced. this week's quotation of $95 representing an advance of $5 per ton. Railroads are showing special interest in far future requirements and considerable business is being placed for 1919 delivery. Pittsburgh quotations on both light and heavy rails have been advanced $5 per ton, the prevailing price being $61 and $62 respectively. The Chicago price on iron and steel bars have been advanced $5 per ton. Local conditions are unchanged but dealers here are anticipating advances on certain lines.

Metals

Little change is noted in the general conditions. The American situation is still influencing the market and until the policy of the government is definitely announced the trade will be rather unsettled. Copper continues to fall off owing to the lack of any heavy buying movement. Tin is the feature this week, having advanced three cents on the New York market. Spelter is stronger on prospective buying. Lead is very firm with independents asking increased prices. Antimony and aluminum are both steady on fair demand.

Copper.—The market is still featured by the unsettled conditions that have prevailed during the past six weeks and prices continue to decline. Prospect of further heavy buying by the American Government has again created something of a sensation in producing circles and it appears doubtful whether additional orders will be considered at the original low figure. While the general tendency in the open market is toward lower levels, the irregularity of existing conditions does not warrant a prediction as to early future conditions. Copper may go still lower but active buying would steady and also strengthen the market. London continues to weaken and New York quotations are easier than last week; prices quoted being 31c for lake and electro, and 27¼c for castings. On a slightly better demand the market here has advanced one cent during the week. the prices quoted being 38c for lake and electro, and 37c for castings.

Tin.—Considerable interest is being shown in the tin situation and activity has increased. The possibility that freer permits will characterize the shipment of tin seems to have developed a special dealers' movement on the part of British buyers and a stronger market has resulted. The recent entrance of the United States into the war has developed quite a complicated situation, owing to the fact that quantities of tin that were being held by German interests are coming on the market, but through fear of having to make explanations the trade is somewhat reluctant about buying this metal. The ever present risk of loss in transport is one of the features of the existing strong market. During the week London has made quite a jump in price quotations and the same has happened in New York; the advance on the latter being 3c per lb. New York is now asking 58¾c per lb. Locally, the market has advanced 2c, the quotation being 58½c per lb.

Spelter.—The dullness that has prevailed in this metal has apparently been halted and a stronger tone has followed recent activity. This appears to have been started when it was reported that heavy additional buying of copper would probably be made by the American Government. This possibility has increased the confidence of the trade and the demand for supply is becoming heavier. The producers are showing the same anxiety as last week and are not so eager to sell. New York's quotation of 9⅝c shows an advance of ⅛c per lb. A stronger tone has developed on the market here and dealers are asking 13 cents, an advance of ½c per lb.

Lead.—This metal continues to maintain its firm position in spite of the fact that the demand has shown some slight falling off, but the producers are showing no concern owing to their heavy bookings for early future requirements. The trust price continues to be quoted at 9c, but some of the independents are asking as high as 10c, this being a ¼c advance over last week. Local dealers continue to quote 12½c on a steady market.

Antimony.—The market has been quiet for spot metal but futures are fairly active. New York is quoting 33½c, a decline on the week of ⅛c per lb. The local market is firm at 27c per lb.

Machine Tools and Supplies

While no definite developments of great activity have taken place in the machine tool circles, the business reported this week is undoubtedly an improvement over that of the past few weeks. The demands for shell equipment are not heavy, orders being confined to single tools for replacements. However, the improvement that has been shown in other lines is a very encouraging factor in connection with the future of machine tool activity. The situation in the States is still unsettled owing to the developments that are continually taking place. Machine tool builders are now in a position to make very good delivery on all classes of tools. Better conditions are evident in the supply market but prices are well maintained.

Scrap

Conditions in the scrap market are comparatively unchanged, prices continuing to fluctuate but with very little variation. The situation in the pig iron market has experienced a quiet week and this has apparently influenced the trade in old metal. With the exception of tin scraps the general quotations on the New York market shows a downward tendency. Local dealers continue to quote last week's prices on a steady and firm market.

Toronto, Ont., May 5.—The new tax on war profits, while more drastic than was expected, has been received philosophically in business circles, and manufacturers are to be commended for the spirit in which they have accepted the taxation. There are not many industrial concerns who will be seriously affected, and the arrangement of the schedule is such that the heavy assessment falls largely on those who are able to pay. General business conditions show no important change, although the scarcity of raw materials continues to handicap manufacturers and is restricting production. The coal situation is perhaps the most serious, for, not only is there a scarcity, but prices are going up, notwithstanding the season of the year when coal is usually cheaper. The outlook for next winter is not at all hopeful, unless some drastic steps are taken this summer to prevent another famine. In any event, it seems that high prices are inevitable, owing to increase in miners' wages and higher cost of transportation.

Steel

Recent developments in the steel market seem to indicate that prices will continue to advance indefinitely. The fixing of prices on steel products for the American Government has not caused any cessation in the upward movement; in fact the tendency is all the other way now that Government's purchases of steel are becoming more clearly defined. The expectation that the Government will ultimately require considerable tonnages of steel at a time when the mills are in a sold-up condition is giving a fresh impetus to the market and forcing prices up. Generally speaking, the extraordinary high prices on steel products are not curtailing the demand as much as might be expected, due principally to the fact that a large proportion of the tonnage is required, either directly or indirectly, for war purposes. Consumers who can wait for their material are staying out of the market until conditions become more favorable, both as to price and delivery. In regard to deliveries, the situation is becoming worse, especially on steel imported from the States, where congestion at the mills is getting more acute as the demand becomes more insistent. The Canadian mills have all the business they can take care of for several months, and as practically their entire output is bespoken for the Imperial Munitions Board, steel for ordinary purposes is very scarce. Although price changes are not so numerous this week, it is no indication of a weakness in the market. Further advances are looked for in the near future, which will affect black sheets, plate, wire products, and possibly bolts and nuts, chain, and tubes. Ship plates have recently sold at 10c base, Pittsburgh. Although business has been done at a lower figure, it is an indication of what may develop over here. Smooth steel wire recently advanced to 6c base for Nos. 0 to 9 gauge, which will doubtless be reflected in prices of wire products. Quotations on hoops and bands are nominal, as most manufacturers have withdrawn from the market until Nov. 1. Bolt and nut prices advanced 10 per cent. in the States, which may result in higher prices here.

Prices of black sheets continue to advance, and the demand in the primary market is getting heavier. The latest advance on sheets is equivalent to $10 per ton, which brings No. 28 gauge to $7.75, and No. 10 to $7.50 per 100 lbs. The United States War Department has purchased a large tonnage of sheets at what is practically the market price. In view of further Government requirements, sheet makers have practically withdrawn from the market. Prices of galvanized sheets have not advanced, but may do so in the near future, although costs are getting almost prohibitive for consumers.

Government requirements in the United States feature the steel market there, and are helping materially to force prices up. Prices of finished steel are advancing, bars being now quoted at 3.50c, and structural shapes 4c, Pittsburgh. Sheet bars have been quoted at $82.50 mill to domestic consumers, while it is reported that 1,000 tons of open-hearth sheet bars have been sold to Canadian interests at $90 mill. Structural shapes, Chicago warehouse, are now quoted at 4.75c. Iron bars have advanced to 3.75c Pittsburgh.

Pig Iron

The situation in the pig iron market remains unchanged. No prices on domestic iron are obtainable, and available supplies are light. At Buffalo practically the same prices as prevailed last week are still current, ranging from $42 to $45, according to the ability of the furnace to supply material, and without much difference as to grade.

Scrap

The scrap market is weaker for red and yellow metals, but firmer as regards heavy melting and similar materials. Copper prices have declined practically 2½c, and brass 1½c. Heavy melting is up 1c, No. 1 machinery cast iron 1c, and malleable scrap 3c. Steel turnings have recovered from the slump last week, and are now quoted at $8. A market for this material will open up probably in July, when the electric furnace plant at Ashbridge's Bay starts operating. In the meantime supplies will accumulate.

Machine Tools

Business generally is on the quiet side, although there has been a fairly good inquiry for radial drills, punches, shears and similar machinery. Tool room equipment continues in good demand, but deliveries are backward. Developments in the States are being followed with interest by local machinery houses, as it is not yet clear what effect the United States participation in the war will have on the trade in that country. Prices of machine tools in the United States are still going up, principally by reason of the increase in cost of pig iron. Some makers of milling machines have announced another advance of 10 per cent. on their product, while others have raised their prices 20 per cent. on high-speed drilling machines.

Supplies

Prices of machine shop supplies continue firm with advances on some lines. A sharp advance of 75c has been made on white lead in oil, bringing the price up to $15.75 per 100 lbs. in ton lots. This is a phenomenal price, and is due to the high cost of pig lead and linseed oil. Gasoline is firm and unchanged, but fuel oil is down to 11¼c in gallon lots. Plumbers' oakum has advanced to 9c per lb.

Metals

Considerable activity has developed in the metal markets, being featured by declines in copper and spelter, and an advance in tin. The market in New York has been unsettled owing to the uncertainty as to the U. S. Government's requirements for war purposes, and the low prices originally fixed on copper. More recently the price of copper to the Government was raised to 25c, which helped to improve the situation. The expectation of a low price being fixed on spelter has unsettled the market for this metal. Tin has advanced, following a higher price in London. Lead continues very firm, but is unchanged in the meantime. Antimony is in good demand, although quotations continue nominal. Aluminum is unchanged.

Copper.—The market is very irregular and prices have declined, but are still nominal. The knowledge that the U. S. Government's requirements for copper are to be heavy, and that a 25c price has been fixed, and that the Allies will soon be in the market is having much to do in strengthening the position of copper. Notwithstanding this and the continued heavy demand, it is likely that prices will decline further. Local quotations have declined 2c, and are as follows: Lake and electrolytic 37c, and castings 36c per pound.

Tin.—The market is stronger and higher both in London and New York. The advance in New York is due to the present limitations on imports and higher cost of freight and insurance. There is also some fear of a scarcity of tin on account of the growing demand. Tin has advanced 2c, and is now quoted at 58c per pound.

Spelter.—The possibility of a low price being fixed on Government purchases has unsettled the market in New York. Early in the week it was reported that the price of spelter had been fixed at 5.85c, but this was later denied. Spelter has declined 1c locally, and is now quoted at 12c per pound.

Lead.—The market continues very firm on good demand. The position of lead is strong, and the expectation of increase in demand is tending to advance prices. Local quotation unchanged at 12¼c per pound.

Antimony.—The demand for spot antimony has fallen off, but futures are more active. The market is strong and prices continue nominal at 36c per pound.

Aluminum.—The situation is unchanged, although an increase in demand is anticipated. Local quotations are unchanged at 68c per pound.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Sydney, N.S., April 27.—The coal production in Nova Scotia is resting at the diminished level of the past six months, no further noticeable decline having taken place. The Dominion Coal Co. output for April will be about 330,000 tons as compared with 380,000 tons last April. For the first four months of the year the aggregate production shows a decline when compared with the first four months of 1916 of 210,000 tons.

Labour matters continue unsettled. A Commission has been appointed by the Minister of Labour to enquire into the question of wages as between the Dominion Coal Co., and its Glace Bay employees. The Commission consists of Dr. Forrest, ex-president of Dalhousie University, Judge Chisholm, of the Nova Scotia Bench, and John T. Joy, a member of the Workmen's Compensation Board of Nova Scotia. The personnel of the Commission is excellent. It is expected that in addition to the consideration of the wage question, the Commission will pay some attention to the disputed questions regarding the miners' unions.

Considerable activity is noticeable in all the coalfields in the opening up of abandoned collieries, and the development of easily accessible coal areas. This is a reflex of high prices for coal, but it can have no appreciable effect on the production of coal, because of the irremovable restriction of the shortage of miners. It may cause an increase in the production of smaller mining companies, but it will cause a corresponding, or probably greater decrease in the production of the large coal companies, because the workmen obtained will be taken from the large concerns, and will be attracted by less onerous working conditions, principally in the matter of the walk to work.

For the first time since somewhere in 1913, there are signs of capital expenditure at the collieries. The Domin-

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbegd No. 4, Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Care British Consulate General, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

ion Coal Co. is largely increasing the production of electricity at its Dominion No. 2 Power House by the installation of a 1,500-kilowatt turbo-generator, purchased second-hand. The installation of second-hand machinery is being forced on companies by the impossibility of getting early delivery of new machinery, particularly electrical machinery.

The work of excavation for new coke-ovens at the Dominion Iron & Steel Co.'s plant has commenced.

CANADIAN RAILWAYS MAKE NEW RECORDS.

THE annual report of the Comptroller of Railway Statistics, Mr. J. L. Payne, tabled in the House of Commons, Ottawa, April 23, shows that the railways of Canada established new high records in regard to practically all branches of the transportation service during the statistical year ending with June last. Gross earnings amounted to $263,527,157, as compared with $199,843,072 in 1915. Operating expenses last year totalled $180,542,259, as compared with $147,731,099 for the preceding year. Net earnings last year totalled nearly eighty-three millions, as compared with fifty-two millions in 1915.

The total operating railway mileage at the end of June last is given as 37,434 miles, which included 1,852 miles of new line added during the year, but did not take into account 3,150 miles additional which was officially classed as being "under construction," although a considerable proportion of this was actually under operation. In addition to the main line track, there are 8,396 miles of yard track and sidings, and 2,489 miles of second line track, thus bringing the total of all tracks up to 48,319 miles.

Capitalization and Aid

The railway capitalization, including capital liability on lines under construction, has now reached an aggregate of $1,975,358,919, not including Government owned and operated lines, adding a mileage of 4,178 and a capital cost of $306,053,937. During 1916 there was an addition to railway capitalization of $18,066,886, made up of $488,487 in stocks and $17,598,499 in bonds.

The total cash aid to railways at the end of June last by the Dominion, the Provinces and municipalities, amounted to $240,062,359. Land grants totalled 43,983,952 acres, while Dominion and Provincial bond guarantees totalled $417,612,941.

The Bawden Machine Co., of Toronto, recently incorporated a subsidiary company called the Bawden Pump Co., for the manufacture of centrifugal and steam pumps for waterworks, sewage, filtration and industrial purposes. They will also make valves and hydrants. The Bawden Machine Co. have been manufacturing steam pumps for some years, but have decided to develop the scope of their business.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Perth, Ont.—Thomas B. Caldwell has purchased the Facer Car Wheel Co.'s plant here.

Vancouver, B.C. — The Vancouver Forge Co., plans extensions to its plant, including the construction of new machine shop.

Niagara Falls, Ont.—The Hydro-Electric Commission are making preparations for the construction of the Chippewa Creek development.

Toronto, Ont.—The Toronto Lock Mfg. Co. have been granted a building permit for an addition to their machine shop on Patterson Place, to cost $2,000.

Montreal, Que.—The American Can Co., New York, will erect a can factory at Maisonneuve, and will call for tenders at an early date. N. M. Loney is engineer.

St. Thomas, Ont.—F. N. Gadsby has opened the blacksmith shop next to the London and Lake Erie car barns, Talbot street west, which was conducted by A. Monteith who enlisted recently.

Windsor, Ont.—The Canadian Lamp & Stamping Co. is having plans prepared by Architect Gilbert Jacques, for an addition to its plant to be 1-storey, 60 x 210 feet, brick and steel construction to cost $25,000.

Sudbury, Ont.—The British American Nickel Co. will build two complete units of the plant near here, and will produce 10,000 tons of nickel a year instead of 5,000, as originally intended.

Dunsmuir, B.C.—The Canadian Colliers, Ltd., has commenced the construction of 120 coke ovens, and is considering 30 coke ovens for the Ladysmith smelter which is preparing to start operations.

St. Mary's, Ont.—Fire on April 22 caused $8,000 damage at the plant of the Thames Quarry Co. The big new stone-crusher building, situated close to the C. P. R. tracks, was burned to the ground. The loss is covered by $3,400 insurance.

Toronto, Ont.—A fire, caused by an overheated oil furnace in the forging shop of the John Inglis Co., Strachan Avenue, on April 24, completely gutted the frame structure, and the machinery was badly damaged by water. The damage is estimated at $25,000.

Sudbury, Ont.—The Board of Control has received a letter from Morris & Hedden, of Buffalo, N.Y., regarding the manufacture in Canada of internal combustion engines of the four-cycle, multiple cylinder type. The firm has been manufacturing in the United States for eleven years, and is thinking of establishing a branch of their industry in Canada.

Cobalt, Ont.—The Northern Ontario Light & Power Co. have taken over the power plant at Charlton, and from this time forward will operate it as part of their large power concern in the north country. The taking over of this plant by the N. O. L. & P. gives this company practically a monopoly of the power plants in the North Country. It is the intention of the new owners to make many improvements and additions to place their new unit on a more up-to-date basis.

Port Hope, Ont.—The Port Hope munition plant, now known as the Port Hope Supply Co., is asking the town to guarantee its bonds to the amount of $50,000. The company, it is said, holds a contract for 3,500 shells per week up to September, and to carry the contract it is necessary to instal additional machinery. Mr. Brandon's proposition is to the effect that the town guarantee his bonds to the amount of $50,000. The matter will be discussed at a public meeting.

YARROW'S LTD. TAKE STERN WHEELER CONTRACT

YARROW'S LTD., shipbuilders of Esquimalt, B.C., have been awarded a contract for the construction of another steel sternwheel vessel, and are expecting daily to sign up contract for a fourth boat, all of them being for the same concern which ordered the two already built by the firm. If the fourth order comes along it means that Yarrows, Ltd., will have two of these steel boats under construction in their yard at the same time, which will add considerably to the general activity in shipbuilding on this coast.

The vessels are to be employed on river service in India. They are 132 feet in length, 32-foot beam, with a draft of three feet, and have accommodation for passengers and freight. They will be capable of making a speed of ten knots. The boats themselves are shipped, knock-down, to India via the Blue Funnel boats leaving Victoria, the parts being marked and placed in crates so that when they reach their destination it is a more or less simple matter to rivet the parts together.

All the machinery equipment, including engines and boilers, is being manufactured at the Yarrow plant on the Clyde, being shipped to India from there. The first vessel built in Victoria by Yarrows, Ltd., was shipped across the Pacific on one of the Blue Funnel liners some time ago and the second one is all ready to be shipped on the next sailing of the Blue Funnel liner Protesilaus.

In these days of steel shipbuilding, it is a very difficult matter to get the steel for the smallest sized vessel. The major portion of that used in the construction of these river boats is being secured by Yarrows, Ltd., from the United States. That further orders are being placed here for these boats indicates the satisfaction with which the owners have viewed the work turned out.

GENERAL

Toronto, Ont.—The Royal Company have been given a permit to erect a one-storey brick factory at 23 River Street, to cost about $7,000.

Oshawa, Ont.—The W. T. Trick Co., whose factory was recently burned down, havet refused an offer of a free site and loan by the town council.

Toronto, Ont.—The Logan Brick Works will construct a brick kiln at 473 Greenwood Avenue at a cost of $2,500, for which they have obtained the required permit.

New Toronto, Ont. — The Dupont Fabrikoid Co., manufacturer of leather goods, etc., will complete its new plant and be ready for operation in about a month.

Kincardine, Ont.—T. B. Watson, proposes to establish a furniture factory and wants the town to assist with a loan of $20,000. A by-law will be submitted to the ratepayers.

Portage la Prairie, Man.—A. Forsythe & Co., grain merchants, of High Bluff, have begun the erection of a big elevator in this city. It will have a capcity of 100,000 bushels. It is understood that the company will erect elevators at other points in Manitoba.

Smiths Falls, Ont.—The Ontario Hydro-Electric Commission has decided to come to Smiths Falls, and negotiations are now under way for the taking over of the power sites acquired by G. A. Burgess at High Falls and Rosebank, on the Mississippi river and for the development of them to supply this town, Perth and other places on the line with power.

MUNICIPAL

Hamilton, Ont.—The Board of Control may purchase a motor street flushing machine.

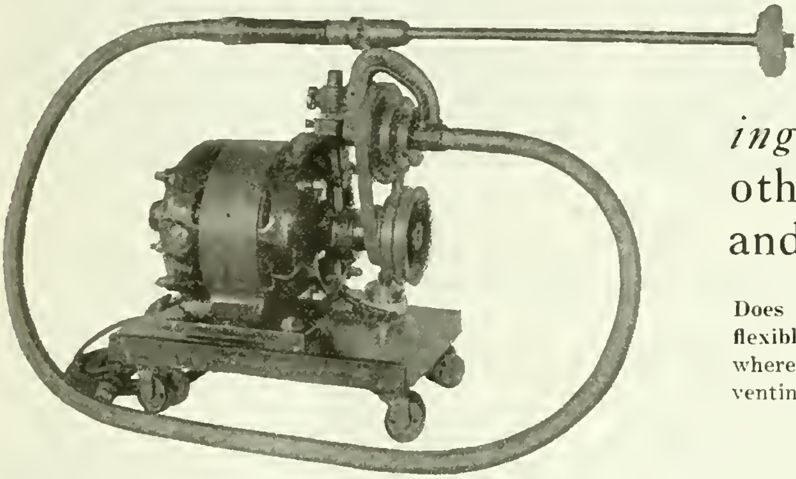
Tillsnburg, Ont.—A by-law will be voted on by the ratepayers on May 14, to raise $10,000 by way of a loan to the Tillsonburg Foundry & Machine Co.

Simcoe, Ont.—Fire Underwriter's Inspector Norman R. Wilson has reported that a number of improvements are desirable to the fire fighting system here.

Aikenhead's M-6 Shell Machine

for cleaning out insides of 4.5 inch Howitzer and 6-inch shells and for retouching rough spots.

This machine has been used with immediate success in a number of large shell factories in Canada. A 14½" special spindle is supplied for 4.5 shell work and a 20" spindle is used on 6" shell work. Specially adapted for cleaning the base of shells *inside*.



The Strand flexible shaft has a *metal casing* that will outwear any other now on the market and adds life to the shaft.

Does away with the trouble common to other flexible shafts. Freely flexible to a certain radius, where it automatically forms a stop, thus preventing accidental short bends.

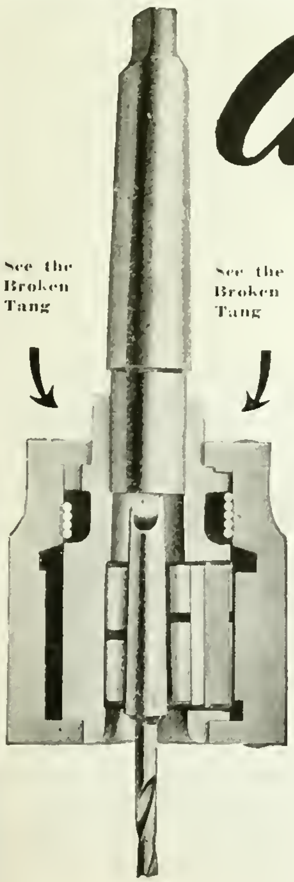
AIKENHEAD HARDWARE LIMITED

17, 19, 21 TEMPERANCE STREET, TORONTO



Aikenhead's New Chuck

Don't Throw Away Broken Tang Drills

Perhaps you are about to discard some taper shank drills because the tangs are broken off—DON'T DO IT—they are worth their weight in gold. You can use them just as they are with a

Wahlstrom Automatic Chuck

One chuck holds drills from 1/16" to 1¼"

and you won't have to take time from your production to repair them.

Tool changes are made in two seconds—just grasp the shell of the chuck with one hand and put in or remove the tool with the other—no collets—no lost time, for the spindle never stops. The jaws grip NOT BY THE TANG, BUT ON THE SIDE OF THE TAPER—there's no chance for slippage—a Wahlstrom won't even mar the shanks.

AIKENHEAD HARDWARE LIMITED

17, 19, 21 Temperance Street - Toronto, Canada

Aylmer, Ont., proposes to spend $7,-000 for the installation of electrically driven pumps for its waterworks system and a gasoline pump for fire purposes.

Wolseley, Sask.—A by-law has been passed by the Council authorizing a loan of $9,000 for extension to the municipal light and power plant and deep drainage system.

Aylmer, Ont.—A by-law to install the Hydro-electric was carried here last Monday by a majority of 288. The power will be brought from St. Thomas, and is expected to be in operation within three months.

Winnipeg, Man.—The letting of the half-million dollar aqueduct contract for cast iron piping, valves and specials, was shelved at a meeting of the administration board of the Greater Winnipeg water district, on April 20.

North Bay, Ont.—The Quinlan by-law will be submitted to the ratepayers on May 7. The J. P. Quinlan Mfg. Co. propose to extend their furniture factory and want the company's bonds guaranteed to the extent of $15,000.

Winnipeg, Man.—Tenders for the supply of cast iron pipe to the Greater Winnipeg Water District were as follows:—United States Cast Iron Pipe & Foundry Co., $393,888.62; Canada Iron Foundries, Ltd., $390.290.56; R. D. Wood & Co., $387,518. No tenders were accepted, and the work will probably be held up until next year.

Alliston, Ont.—A by-law will be voted on by the ratepayers on May 7 to raise $32,000 to provide for the taking over of the Alliston electric light plant and repairing and improving same for the purpose of distributing electric power to be supplied by the Hydro-Electric Power Commission.

Winnipeg, Man.—Tenders for the supply of valves for the Greater Winnipeg Water District were as follows:—Crane Co., Chicago, $15.038.70; Canadian Fairbanks-Morse Co., $12.749.92; Kennedy Valve Co., Elmira, $12.345.44; Rensselaer Valve Co., Troy, $12.196.54; General Supply Co., Winnipeg, $12,184; Drummond, McCall Co., Montreal, $11,138.25. No tender was accepted.

Port Hope, Ont.—The Town Council has approved of the Nicholson File Co. proposed extensions. The company will build a foot bridge over the river and extend their plant at a total cost of about $40 000. The council has agreed to submit a by-law to the people, giving the company a fixed assessment of $35.000 for ten years. Bowman & Connor, engineers, have been requested to make a report on the proposed bridge.

ELECTRICAL

Hamilton, Ont.—City Engineer Gray reports that additional transformers are required for the Beach pumping station. The cost is estimated at $20.000. The Board of Control has the matter under consideration.

PERSONAL

F. N. Sinclair, of New Westminster, B.C., has been appointed a Dominion pilot commissioner for the pilotage district of New Westminster.

T. M. Jones, of Canadian Allis-Chalmers, Ltd., has joined the staff of the Bawden Machine Co., Toronto, as chief engineer and general manager.

John Collins who has been with the Canadian Steam Boiler & Equipment Co., Toronto, has been appointed manager of H. L. Peiler & Co.'s Toronto office in the Kent Building.

C. N. Schrag, sales engineer of the Ontario District Office of Canadian Allis-Chalmers, Ltd., has resigned to become general sales manager of the Bawden Machine Co., Sterling Road, Toronto.

T. S. Downham is again actively connected as manager with the Canadian Steam Boiler & Equipment Co., Toronto, after a holiday of several months duration. Mr. Downham has fully recovered his health.

Capt. John Baillies, a well-known seafarer, who has plied for years on the British Columbia coast, has received instructions to report to the senior naval officer at Esquimalt for appointment under the new regulations whereby master mariners are taken into the naval service with the rank and pay of "skipper." Captain Baillies is a deepwater man, but for many years has been in the coasting service, and at present he is with the G.T.P.

R. P. Butchart of Victoria, B.C., has been requested by the Imperial Munitions Board to associate with the Board in its work of shipbuilding on the Pacific Coast. A large organization will have to be formed in connection with the plans decided upon for the building of a large number of wooden ships. Mr. Butchart will act as business adviser and will have supervision of the organization on the coast on behalf of the Board. Mr. Butchart is a leading Victoria business man, head of the Pacific Cement Co.

W. Shives Fisher, of the hardware firm of Emerson & Fisher of St. John, N.B., has on request of Sir Edward Kemp, Minister of Militia, on behalf of the Government, accepted an appointment as commissioner in charge of the Dominion rifle factory, formerly the Ross rifle plant, during the period of appraisal. Mr. Fisher is being placed in complete control. His work will involve matters of supplies and outstanding contracts, as well as the investigating of any disputes arising.

Lieut.-Col. T. C. Irving, was recently gazetted as colonel in the 4th Canadian Division. Col. Irving left Toronto with the First Canadian Contingent as a captain in charge of the 2nd Field Company of the Engineers. Capt. Irving received the D.S.O. at the Battle of Langemarck, and shortly afterwards obtained his majority, while the latest gazette raises him to the rank of lieutenant-colonel. Lieut-Col. Irving was formerly vice-president of the C. W. Hunt Co., engineers and the Moffat-Irving Steel Works, Toronto.

George Bury, vice-president of the C.P.R., has arrived in Montreal from Russia, which country he visited at the request of the British and Russian Governments in connection with transportation. He was present in Russia during all the recent revolution. Mr. Bury said that his experience gained by close personal contact and association with Lord Shaughnessy, enabled him to make recommendations which were accepted by the old Russian Government as well as by the new who are now putting these recommendations into force with great vigor.

CONTRACTS

Montreal, Que.—The Board of Control has awarded a contract for the construction of the Lasalle bridge over the aqueduct to A. Pion at the price of $277,000.

East Angus, P.Q.—The Brompton Pulp & Paper Co. have awarded a contract to the Canadian Allis-Chalmers, Ltd., for water turbines and governors, value $100.000, and to the Canadian General Electric Co., for generators, exciters, transformers, etc., at $150,000.

Toronto, Ont.—The Otis-Fensom Elevator Co. have tbeen awarded the contract for nine elevators for the new Union Station. The price is understood to be about $200,000.

Montreal, Que.—The Board of Control has decided to buy twenty flushing and street cleaning automobiles at a cost of $146,415. The contract for ten flushing machines was awarded to A. Jennings & Co., furnishing a Kelly-Springfield truck chassis, and the ten sweeping machines will be supplied by the Comet Motor Co., with Packard truck chassis. The flushing machines will cost $7,399 each and the sweeping machines $7,-242.50 each, making a total of $146,415.

Trenton, Ont.—Pierhead construction, it is said, has been contracted for at a cost of $600,000 by the Harbor Commission. The contracts are split among three concerns—R. Weddell & Co., Trenton and Toronto; Port Arthur Construction Co., and J. O. Roddick, Toronto. These three contracts will constitute the summer work on the harbor improvements, and call for the construction of crib superstructures and concrete superstructures of the inner harbor wall. The total distance is 6.000 feet, and it is understood that each concern contracts to construct 2.000 feet of wall.

TRADE GOSSIP

The Burlington Steel Co., of Hamilton, Ont., has increased its capital stock to $650,000.

Hudson Bay Railway.—According to a statement made by Hon. Frank Cochrane in the House recently, the Dominion has spent $17,790.587.74 on the Hudson Bay Railway and Port Nelson terminals.

The Canadian Fairbanks-Morse Co., Toronto and Montreal are asking extended powers to permit of engaging in other manufacturing business than is granted under present articles of incorporation.

War Trophies on Exhibition.—A varied assortment of Vimy Ridge trophies, machine guns, mortars and field guns are being prepared to be shipped out to Canada. These will be a feature of the Canadian National Exhibition at Toronto in August.

B. C. Coal By-Products.—An important branch is to be added to the Mining Department of the Government of British Columbia by the Hon. William Sloan. Special investigations have been made, and it is believed that many useful coal by-products can be exploited for the benefit of the Province.

The Wetmore Mechanical Laboratory Co., of Milwaukee, Wis., makers of special tools such as milling hobs, reamers, taps, etc., for shell production, have opened an office at 608 Kent Building, Toronto, in order to take care of their increasing business in Canada. P. B. Rogers secretary-treasurer of the company is manager of the Canadian office.

Fish Concerns Amalgamate. — An amalgamation of fishing interests in which are merged several of the oldest houses in the fish business in the provinces of New Brunswick, Nova Scotia and Quebec has been consummated, and the new concern is now known as the Leonard Fisheries Ltd., with headquarters at Montreal, with branches throughout the three provinces named, and with a capitalization of $1,000,000.

G. T. R. Asks Higher Rates.—Presiding at the Grand Trunk meeting in London, England, on April 26, Chairman Smithers said if railways were to continue to exist, higher rates must be charged. Manufacturers and farmers were all highly prosperous, and could afford to pay more, or the railways could not continue to expand their accommodation on which the prosperity of manufacturers and farmers depended in the long run.

Copper Mining in Newfoundland.—The Colonial Government is assisting in the work of developing copper mining activities on the northeast coast of Newfoundland, in the expectation of providing additional supplies of the metal for the Allies. Three large mines in the vicinity of Notre Dame Bay were worked profitably by old methods forty years ago. It is estimated that many million tons can be recovered under modern means.

Embargo on Tin Plate Likely.—Tin plate users and canners in Canada are much perturbed over the possibility of the American tin manufacturers placing an embargo on tin plates and cans. The shortage there is such that canners have been urged to can only perishable fruits, so as to conserve as far as possible supplies. Most of the tin supplied Canada comes from the States, and the proposed embargo would be a serious thing for consumers here.

Quebec, Que.—C. C. Laplerre, of Montreal, has organized an independent cement company that will operate the property owned by the Canada Cement Co., at Neuville, in the county of Port Neuf. This property was bought by the cement merger from the Eastern Canada, the price being a few hundred thousand dollars. The company had already started the building of a mill. The capital of the new company is $1,250,000, and it is planned to have a daily production of 1500 barrels per day.

Toronto Customs Record.—All records were broken again in April, by the Toronto customs returns, which are approximately given at $3,650,000 or about $900,000 in excess of the figure for the same period last year. These figures beat those of March which were $3,494,174.87 and constituted a record. The total for the four months of this year is $13,232,413, compared with $10,303,860 for the first four months of 1916, and just a little over two and a half millions less than the total for the whole period of twelve months in 1915, which was $15,821,426.

Britain Orders 30 New Steel Ships in Canada.—Sir Thomas White announced in the House on April 23, that orders had already been placed by the Imperial Government for 22 steel vessels in Canadian shipyards. A further order for eight steel vessels would be placed and these ships would total 175,000 tonnage. All the plants in Canada had orders sufficient to carry them into the middle of 1918. He had taken up with the Imperial Munitions Board the question of building wooden vessels in Canada. He was prepared to furnish a ten-million-dollar credit for the building of wooden vessels.

Massey-Harris Reorganization.—At a meeting of the Board of Directors of the Massey-Harris Co., held in Toronto on April 24, the reorganization necessitated by the death of Sir Lyman Melvin-Jones, who for many years was president and managing director, was considered and partially completed. Thomas Findley, former vice-president and assistant general manager, was elected president and general manager; Joseph N. Shenstone, formerly treasurer, was elected first vice-president; C. L. Wisner, formerly secretary, was elected second vice-president, and George Valentine, formerly assistant to the general manager, was appointed general manager.

Investigate White Pine Rust.—Plans for the further investigation into and control of the white pine blister rust have been outlined by the Hon. Martin Burrill, after consultation with the authorities of Ontario and Quebec who will co-operate. The disease destroys much valuable timber, the heaviest infestation being in the Niagara district and certain parts of Quebec. W. A. McCubbin, of the Federal Department of Agriculture, has been appointed to make scientific investigation and co-ordinate efforts in stamping out the pest, while the provinces will co-operate in "scouting" work.

ILLINOIS TOOLS
THE manufacturer who includes ILLINOIS ALL-QUALITY TOOLS in his equipment is preparing himself to produce work of the highest degree and at the same time handle greater volume. A fact proved by *results obtained* in many of the country's largest factories.
It will be to your advantage to confer with our engineering department, no matter what are your Hob and Cutter requirements. Standard tools in stock. Prompt delivery on specials. Write or wire for quotations.

ILLINOIS TOOL WORKS CHICAGO
WHITWORTH

Ross Rifle Factory Expropriation.—A copy of the Order-in-Council passed a month ago providing for the expropriation of the Ross rifle factory at Quebec by the Government was tabled in the Commons on April 24. The Order provides that the price to be paid for the property owned by Sir Charles Ross shall be determined by the Exchequer Court, but shall not exceed three million dollars. It is further provided that Sir Charles Ross shall not receive anything in consideration for the site which was granted to him for the factory when the original contract was made in 1902, but that this site shall revert to the Crown.

Commission Reports on C. N. R.—The special commission appointed to investigate the affairs of the Canadian Northern Railway has submitted its report to the Dominion Government. The commission was composed of Edward E. Loomis, president of the Lehigh Valley Railway, and John W. Platten, president of the U. S. Mortgage and Trust Co., New York. They were assisted by the firm of railway experts, Coverdale & Colpitts, of New York. The report is of considerable length, and is entirely favorable to the railway. It states briefly that the transcontinental undertaking is fundamentally sound, and that the capital invested has been economically secured and wisely expended.

Toronto Union Station.—The work is proceeding in a manner, considering war time, that is satisfactory to the engineers, and they declare that the contracts are not more than two months behind the original time specified. Chief Engineer J. R. W. Ambrose stated recently that wings could be ready for occupation about a year from next August, and that the station proper would be completed about two years from now. The structural steel work will be completed about May 15, while it is hoped to have the wings enclosed by the stone work within six weeks. The masonry work is progressing favorably, and the walls up to the main floor of the station proper are nearly finished, and it is expected that all the stone will be in place within the year.

Canadian Shipping Increased in March.—An increase in the tonnage of shipping on the Canadian register took place during the month of March, according to statistics prepared by the Department of Marine, Ottawa. At the close of February there were steam vessels with aggregate tonnage of 794,314 tons, and sailing vessels of total tonnage of 475,693 registered in Canada. At the end of March the tonnage of steam vessels was 812,906, and of sailing vessels 476,301. During the month steamers aggregating 26,677 tons were added to the register, chiefly by transfers from Great Britain, and 6,628 tons were stricken off by reason of wrecks or unfitness for use. Sailing vessels of an aggregate of 6,294 tons were added to the list, and others of 5,686 tons, which were wrecked or broken up as unseaworthy, were dropped from the register.

No Time Extension on Demurrage Rates.—The Dominion Railway Commissioners have refused to grant the railways an extension of the time over which the increased demurrage charges may apply. Accordingly, after the end of the month the old rates and duration of free time will apply. Last fall, on account of the great car shortage that prevailed throughout America, permission was granted the railways to increase the charge of one dollar per day for each day a car was held after the expiration of the free time to a graduated one that reached five dollars per day within a few days after the expiration of this free time. The length of the free time was also decreased. The railways have recently submitted to the board a new set of car demurrage rules containing several contentious clauses, and in which $3 per day demurrage is asked after 48 hours free time has elapsed.

TENDERS

Toronto, Ont.—Tenders will be receivable up to May 5, for supply of approximately 100 tons of pure soft pig lead for the York Township. Further information may be obtained at Township Engineer Frank Barber, Toronto.

Winnipeg, Man.—Tenders for the additions to the city light and power plant at Point du Bois, decided on in January by the city council, are to be called at once and will close May 15, so that no time will be lost in taking advantage of the summer working season. The new work which will include the installing of generators sufficient to carry the constantly increasing load for many years to come, will cost approximately $180,000.

Trenton, Ont.—Tenders will be received until May 15, for the erection of a nine-roomed Collegiate Institute in the town of Trenton, Ont. Plans and specifications may be seen at the Architect's office or at the office of C. W. Saylor, Chairman of Committee, Trenton. All information, tender forms, etc., may be had at the office of S. B. Coon and Son, Architects, Excelsior Life Building, Toronto Street, Toronto.

Dungannon, Ont.—Tenders, addressed to the undersigned, will be received up to May 12, for the material, plant and equipment of the Ontario West Shore Railway between Goderich and Kincardine. The material is practically all on the right-of-way, and consists approximately of six pairs of steel bridge girders for bridges of 25 ft. to 70 ft. spans; 2,400 cedar fence posts, 8 ft.; 710 boxes of spikes (about 324 lbs. to box); 135 boxes of bolts (about 125 lbs. to box; a large quantity of fish-plates; one engine, three flat-cars, scrapers, etc., used in construction work; a quantity of square timber, from 8 ft. to 24 ft. long; about 2,000 feet of 2 in. hardwood plank; about 900 tons of 70-lb. steel rails.; also fourteen miles of track of 70-lb. rails, bolts, spikes, fish-plates, ties, bridges, etc., laid complete. For further particulars apply to the trustee, Thomas Stothers, Dungannon, Ont.

BUILDING

Toronto, Ont.—A building permit for a one-storey brick warehouse at the corner of Dufferin Street and Lappin Avenue, was granted to the Royal Flying Corps by the city architect.

Toronto, Ont.—The City Architect has issued a building permit to Western Canada Flour Mills Co., for the construction of a three-storey reinforced concrete warehouse and elevator, on Macpherson avenue, near Poplar Plains, at a cost of $20,000.

Toronto, Ont.—The Dominion Waste Co. will soon erect a three storey brick addition to their warehouse and an additional storey to the warehouse at the southwest corner of Paton Road and Browns Road at a cost of $20,000. The building permit for the work has been taken out at the City Architect's Office.

Toronto, Ont.—The Wellington Properties Corporation, will erect a seven-storey reinforced concrete warehouse building costing $300,000, on the Baldwin Estate property at the corner of Bay and Wellington Streets. The first two stories will be Indiana limestone, and will have a frontage of 212 feet on Bay Street with a depth of 73 feet on Wellington Street.

WOODWORKING

Collingwood, Ont. — Wilson Bros., whose planing mill was recently destroyed by fire will probably rebuild. The company has been reorganized and tenders are being called for clearing the site and purchase of scrap.

Toronto, Ont.—A syndicate headed by M. K. Haney is understood to have taken over the lumber mill and plant of the Canadian Pacific Lumber Co., at Port Moody, B.C. The mill, which is situated on Tidewater at Burrard Inlet, will be improved and operated to its full capacity. Associated with Mr. Haney are Richard P. Gough, C. A. Barnard and J. F. M. Stewart of Toronto.

RAILWAYS—BRIDGES

Ottawa, Ont.—The Manitoba & Ontario Railway Co., is applying to Parliament for an act of incorporation authorizing the construction of a railway line from Brereton Station, on the National Transcontinental, in Manitoba, to the English River, in Ontario, and thence northerly to Hudson Bay, between the mouths of the Albany and Nelson rivers.

Windsor, Ont.—A fire, supposed to have originated from spontaneous combustion, broke out in the Kingsville car barns of the Windsor, Essex & Lake Shore Railway on April 25. Three passenger coaches and an electric locomotive were badly damaged; they will be out of use for some time. General manager Eastman was unable to place a close estimate on the damage, but the material and equipment in the barns represented $150,000.

Toronto, Ont.—Good progress is being made on the construction of the Bloor street viaduct, and it is the opinion of

Works Commissioner Harris that the Rosedale section will be open for traffic from Parliament street about the end of July. There is no possibility, he states, of the viaduct being completed and ready for through traffic before the summer of next year. The agreement with the contractors expires on December 24 of this year, but the work has been greatly delayed by the severe weather, and it will likely be late spring of next year before it is completed.

MARINE

Pilot Charges Raised.—An Order-in-Council has been passed increasing pilotage rates. The charge for pilotage for any sea-going vessel has been increased from \$3 to \$3.25 for each foot of draught, and for coasting vessels, from \$2.50 to \$2.75, but the charge for inland vessels remains at \$2.50.

Sault Ste. Marie, Ont.—Ice conditions at Whitefish Point this year have delayed navigation at least ten days past the time that the freighters are usually able to proceed on their course up the lakes, which will mean a big loss to the shipping interest. A large number of vessels have been held up at the Soo.

North Vancouver, B.C.—The auxiliary schooner Jesse Norcross, which was launched on April 25 at the Wallace Shipyards, was named after J. Norcross, vice-president and managing director of the Canada Steamship Lines, director of Canadian-Vickers, and recently appointed by the Dominion Government to have charge of the national shipbuilding scheme.

Sarnia, Ont.—The deal whereby the holdings of the Reid Wrecking Co., including tugs, steamers, etc., with the exception of the drydock property, are to be disposed of to outside parties, is still pending, according to the statements of the officials of the company. No further details of the transaction, than those already published will be given out by the company until the deal is consummated.

Haileybury, Ont.—The boats of the Temiskaming Navigation Co., which ply between points on Lake Temiskaming, with headquarters at Haileybury, have been sold to Mr. Seymour, the member for Pontiac County, representing Ville Marie interests. The line will be operated this coming season under the name of the Ville Marie Navigation Co. Mr. W. Chenier, of Ville Marie, is the new manager.

Victoria, B.C.—The speedy C. P. R. steamer Patricia, which regularly maintains the service between Nanaimo and Vancouver, is again on the ways at the Victoria Machinery Depot for the third time within about as many months, the cause of her being laid up on the present and the last previous occasion being the same in both cases, namely, that the vessel struck some submerged object resulting in injury to one of her propeller shafts.

Victoria, B.C.—The G. T. P. steamer Prince Rupert will be repaired at Yarrows, Ltd., Esquimalt. Reports already received here from Prince Rupert and the scene of the wreck indicate that the damage is very extensive, extending over a length of 180 feet. The repairs are expected to take a period of about three months. The difficult feat of salving the Prince Rupert was carried out by the B. C. Salvage Co., under the direction of Capt. T. Thompson.

Ferry "St. Louis" Sunk.—The St. Louis, owned and commanded by Captain P. McLean, sank on the morning of April 20, at its moorings in the Elgin Basin, Montreal. The vessel had seemed all right when the captain left it on the previous night, but at 7 o'clock the following morning only the bow was above the water, being held in that position by the mooring ropes. The St. Louis has been in the Verdun and La Tortue ferry service for the last ten years. Ice is stated to have caused the sinking. The vessel, which is of 269 tons, will be raised.

Canadian Vessel Rammed.—The Canadian freighter Durley Chine, bound in ballast from a Canadian to an American port, was rammed and sunk on the morning of April 22, in collision with an out-bound British freighter, about sixty-five miles east of Sandy Hook. The latter vessel returned to New York with her bow stove in, leaking badly forward, and brought in the captain and the twenty-eight men of the crew of the Durley Chine. She will probably discharge her cargo and go into dry dock for repairs. According to the captain of the damaged vessel, he left New York the previous afternoon. His vessel struck the Durley Chine amidships and almost cut her in two. The Durley Chine was a single screw steamship of 1,918 gross tonnage, built in Sunderland in 1912, and owned by the Canadian Government. She was 279 feet long, 40 feet one inch beam, and 18 feet four inches deep of hold.

INCORPORATIONS

J. & P. Davignon Ltd., has been incorporated at Ottawa with a capital of \$45,000 to carry on business as contractors and engineers at Montreal. Incorporators are Joseph and Pierre Davignon and Joseph A. Lacasse all of Montreal.

C. L. Perkins Ltd., has been incorporated at Toronto with a capital of \$45,000 to take over as a going concern the business of C. L. Perkins Machine Co., Ottawa. Provisional directors are James P. McMullen and Matthew J. Armstrong of Ottawa.

Welland Shipbuilding Co., has been incorporated at Ottawa to carry on the business of constructing ships and other general construction business at St. Catherines, Ont. The incorporators are Francis H. Keefer, Harold A. Keefer and Donald Munro all of Thorold, Ont.

Ontario Molybdenum Co., has been incorporated at Toronto with a capital of \$40,000 to carry on the business of mining, smelting and refining metals. The head office is at Toronto and the incorporators are Theodore Burrel, Irene O. Allan and Lily Guylar all of Toronto.

INDEX TO ADVERTISERS

Machining the 18 Pounder High Explosive Shell

By A. F. Menzies

Although in the initial period of Canada's munitions industry, the production of 18-pdr. high explosive shell contributed no inconsiderable part of the general activity, the demand for this size and type projectile fell off comparatively early, and gave little promise of being again revived. A few months ago, however, further orders were placed with our metal-working plants, the machining procedure of the latter constituting the subject of this article.

THE operations, methods and devices herein described were observed in a shop turning out four hundred 18-pdr. high explosive shells every twenty-four hours. The work carried the shells to the plugged stage, the banding, varnishing, etc., being done at a central plant. As the shifts were of 11 hours each, operations for which there was only one machine had to be arranged to allow of their being performed in not more than three minutes, including an allowance for changing and setting tools, etc. This gave an output of 20 shells per hour, which allowed for losses due to defective material and rejections. The equipment employed consisted in the main of standard machine tools fitted with special attachments, which were all made on the premises. Special single purpose machines were built for some of the operations, same also being designed and built in the shop.

Cutting Bars to Length

The shell steel was received in bars of varying length up to 10 ft. 3 in., and was measured with a long rule graduated on one side in feet and other side in billet lengths. The first operation was to cut the bars into lengths of 19¾ in. on two Racine high speed draw-cut hack saws. The saws were speeded to 112 strokes per minute, and made a cut in about 11 minutes. The blades 10 in. x ¾ in. x 18 gauge, had 11 teeth per inch, and were supplied by H. Disston & Sons. They were changed whenever the time to make a cut had risen to about 14 minutes. From 8 to 10 blades per shift was found to be sufficient. The discarded blades, while too slow for this work, had still a lot of life in them, and were kept for cutting the square shank off the base-plates and for cutting soft steel. A convenient table was provided to serve the saws. It was built to hold sufficient steel to run a shift, and was filled night and morning by the day shift. The height of the table was such that the operator could easily roll the bars into the rollways leading to the saws. Fig. 1 shows the saws with the steel table behind them.

The second operation, parting the 19¾ in. piece into two billets was done on a special machine. This consisted of a cast iron head carrying a hollow spindle. The head was secured to a pair of I-beams which formed the bed, and which also carried the compound rest. The piece to be parted was pushed into the hollow spindle, and secured with two set screws. The parting tool was a piece of 3/16 in. x 2 in. high speed steel held in a mild steel holder. The tool was fed into the work by hand until the parting was about 1¾ in. diameter, after which the piece was withdrawn and broken across a length of shafting secured to the floor. The broken end was made the base of the shell, and the fracture was examined by the Munitions Board examiner before more work was done on the billet. For examination, the billets were stacked fractured ends up in a box holding a series. After being examined and found O.K., the acceptance mark was placed on the billet. The parting machine is shown on the extreme left, in Fig. 1. It was driven at 67 revolutions per minute by a 6 in. quarter-turn belt.

FIG. 1. SAWING AND PARTING BILLETS.

Drilling Billets

The drilling was done by the inverted method, three machines being used, two of which are shown in Fig. 2. This method of drilling has much to commend it in comparison with the usual method of using twist drills. The billets being inverted, the chips fall out readily and the cutting compound is delivered to the place where it is wanted. Excellent proof of this is obtained by feeling a billet drilled in the usual manner and then feeling one drilled by the inverted method. The latter will be found quite cool, while the former will be found, quite often, too hot to handle. The billet was held in a chuck which was machined from a piece of shafting, the chuck being fitted to the drill press spindle by the usual taper shank. A hollow-headed set screw locked the billet in place while adjustment for varying size of steel was obtained by four set screws located at 180 degs. from the locking screw.

The drill bar was of tool steel, 1¾ in. in diameter, and had two flutes milled in it for the egress of the chips. Two slots were also provided, into which were soldered brass pipes to carry the cutting compound. The lower end of the bar was secured to a flange bolted to the drill press table and carefully lined up with the spindle. The upper end was slotted to take the drill bit and a small pin was provided to hold it central. The bits were of high speed steel machined to shape and hardened and ground. The time taken to drill a hole was between seven and eight minutes.. After being drilled, the fracture was faced off the base end. The machine used on this operation was similar to that for parting. Care was taken to see that a good surface was left on which to start the centering drill. A Rockford Lathe & Drill Press Co. sensitive drill was used for centering, a large cast iron table being substituted for the original small one because giving a better bearing for the swinging table which carried the centering post. The upper end of the centering post was ground to the same angle as the drill bit. thus centering the base end. The post. being a close fit for the hole, assisted in holding the billet true.

Rough Turning

Rough turning was done on the machine shown in Fig. 3, which is a 24-in. MacGregor, Gourlay lathe, fitted up with a roller chuck. Two tools were used, one at the back, held in a heavy cast iron holder, being of high speed steel, while the front tool was ½ in. square stellite held in a No. 6 Efficiency holder, secured in the regular tool post. A jet of cutting compound was directed on each tool, that serving the back tool being made to point upwards and discharge on the work just before it reached the tool. The back tool holder was a fixture, and the tool was adjusted by setting it to a gauge. The size was made with the front tool, and was regulated by the cross feed. It was not necessary to set the tool for each shell, however, as, when the tool had reached the end of the shell, the lathe was stopped and the shell removed. The carriage was then run back and another shell put in. The lathe was next started up. This procedure was kept up until through wear the front tool required adjusting or grinding. The roller chuck shown in the illustration had three 7/16 in. hardened steel rollers working on a hardened cam. It gave excellent results and was very quick. The size made in the rough turning operation left about .03 in. of stock for the finish operation. The speed of the work was 96 revolutions per minute, giving a surface speed of 88 ft. per minute, figured on the original diameter. The feed was 22 per inch. The actual time required to make a cut was 2 min. 20 sec., while it required 20 sec. to take a shell out and put in another.

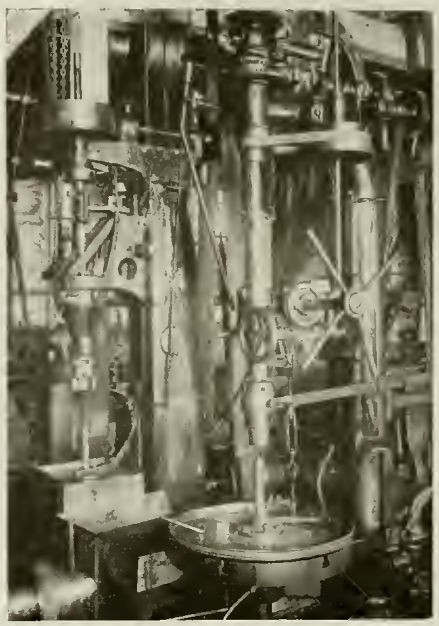

FIG. 2. INVERTED METHOD OF DRILLING

Rough Nosing

The next operation, rough nosing, was done on the special machine shown in the foreground in Fig. 4. It is similar to the other specials, except that the head was geared and the tools revolved while the work was held in a vise. Three forming cutters and a facing cutter were used, the latter to bring the shells to a standard length. As the work being done increases from a very light cut at first to a very heavy one when the facing off cutter got into action, a hand feed was adopted. The machine did excellent work, as many as 265 shells having been put through in a shift. The rate of revolution was 34 per minute. The vise had one fixed and one movable jaw, the latter being fitted with four hardened insets, which had teeth cut in them to grip the shell.

Outside Finishing and Profiling

The outside finishing and profiling were done at one operation on an 18-in. American lathe, shown in the background in Fig. 4. The machine was fitted up with a profile bar and a roller 2 in. in diameter, kept in contact with it by means of a helical spring. The profile bar was mounted so as to be adjustable transversely. The cross slide screw, of course, was removed, the size being made by adjusting the compound rest. The same procedure to avoid changing the tool setting was adopted here as that used on the rough turn lathe. The tool, ½ in. square high speed steel and sometimes stellite, was held in a block holder, adjustable longitudinally, in order to bring the profile in the correct location. The rate of revolution was 200 per minute, while a feed of 28 per inch was found to be satisfactory. To drive the shell, a three-jawed chuck gripping in the hole was used; it was operated by a hand wheel (late steering gear of a Ford car), working on a screwed rod passed through the headstock spindle. The hanging mallet was used to tap out the rod and expanding cone after slackening the wheel.

To assist in obtaining concentric bores, a rough boring machine was used. This was a special machine fitted with a collet chuck and a hand wheel for operating it. The tool was held in a bar carried in a travelling head, which was fed into the shell by a screw driven from the headstock spindle. A cone friction was used on the feed and the return was by hand.

Finishing Bore

Finishing the bore was done on two LeBlond lathes, one of which is shown in Fig. 5. The illustration shows three

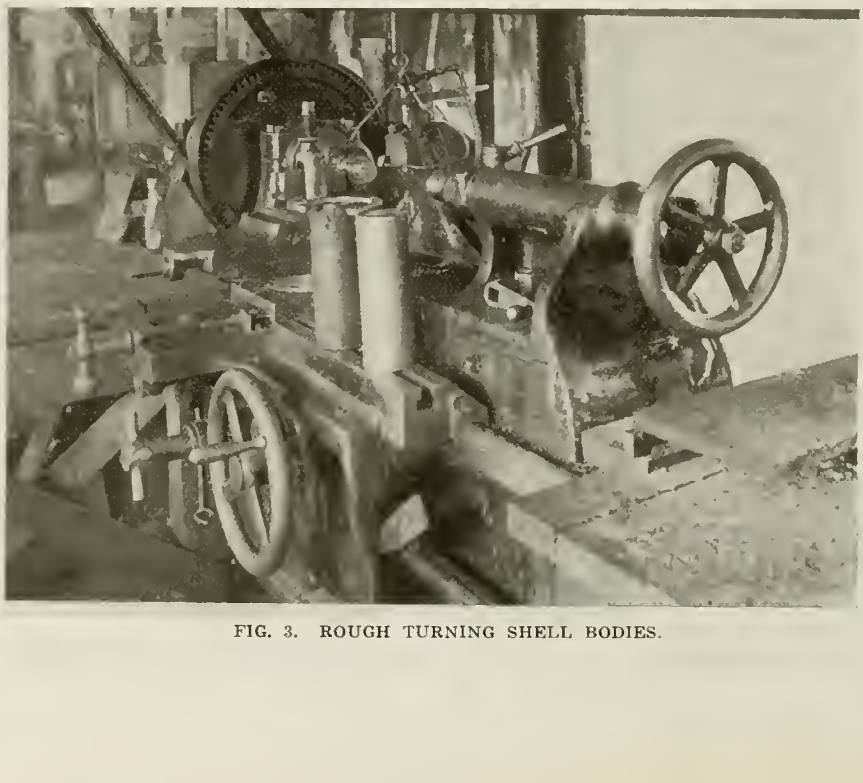

FIG. 3. ROUGH TURNING SHELL BODIES.

bars the one pointing to the shell was not, however, regularly used, it carried a point tool and was only employed if the rough boring machine was out of business. The first cutter enlarged the hole to about 1.70 ins. in diameter and hogged out the bottom. The second cutter made the finish size and depth; as very little stock was left for this tool to take out a good finish was easily obtained. The lathes were both fitted with collet chucks having hand wheels for operating them. The turrets were very substantial, as can be seen from the illustration, a large bearing being provided for them to turn on. Cutting compound was fed through pipes let into the boring bars, and which communicated with the hollow turret stud to which the supply pipe was attached.

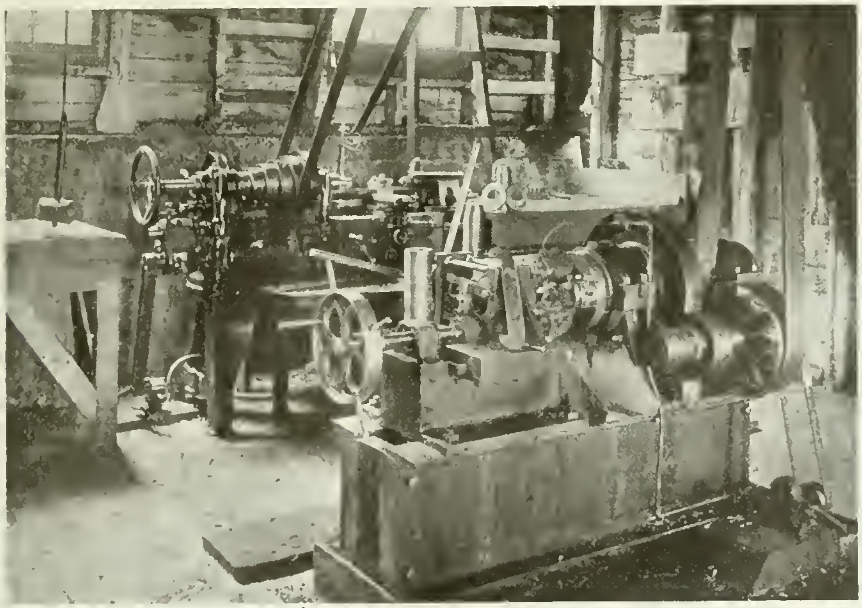

FIG. 4. ROUGH NOSING AND PROFILING

It may be mentioned here that all lathes on chucking operations were fitted with similar chucks, except the machine on the band recess. The chuck bodies were of cast iron, while the jaws were of chrome nickel steel. The jaws were operated by a nut, on the outside of which a hand wheel was keyed. The hand wheels proved to be great time savers. Cutting compound was fed to each machine by individual geared pumps, belt driven from any convenient revolving part. This method allowed of varying the compound to suit the particular work and was also useful when experimenting with new compounds.

Nose Operations

Boring out the nose of the shell, forming the nose, and undercutting for the fuse thread formed the next operation. It was carried out on a 16 in. MacGregor, Gourlay lathe, fitted with a turret secured to the saddle. The turret was of similar design to that used on the inside finish; but was a little smaller. The shell was located in the collet chuck by means of a cup fitting on the profile and secured in the turret, the method being to place the shell in the chuck and tighten it slightly. The shell was then pressed home in the chuck by the cup, until the saddle came in contact with the stop, when the shell was firmly tightened. The shell was then correctly located in regard to the tools in the turret.

The fuse hole was first bored out with a point tool, the boring bar also carried the two bevelling tools required to finish the nose. Power feed was used until bevelling tools began to cut, when hand feeding was resorted to. The fuse hole undercut was put in with a tool mounted on a sleeve working on an eccentric bar. The tool was formed to make the undercut and also to slightly round off the under shoulder. A small bevelling tool was also mounted in this holder and was used to bevel the mouth of the hole to prevent a rag being set up when milling the thread.

Copper Band Recess

The band recess was put in on a 16-inch C.M.C. lathe, fitted with a special attachment in place of the cross slide. The shell was held in a three jaw Cushman chuck and was located by a stop striking the bottom of the hole, the base of the shell being carried on the tail stock centre. The special attachment was fitted up with four tools. The first, a roughing out tool, was carried in a holder under the shell and was brought into action by drawing the attachment toward the front. As the tool passed the centre, it finished its cut and brought the attachment up against a stop which located it correctly for the two undercutting tools carried inverted in a block at the back. The undercutting tools were held in blocks fitting into slides planed to the angle of the undercut. They were fed to the work by one revolution of an eccentric spindle, and returned by springs.

To form the waved ribs, the attachment was run back against a stop, bringing the cam and roller into engagement, causing the ribbing tool to reciprocate. The ribbing tool was fed in by hand against a stop giving the correct size. Fig. 6 is a view of the machine showing the attachment. The work turned out was exceptionally good and there was no difficulty in getting the rated capacity.

Finishing Base Recess

A 16-inch Le Blond lathe was used to finish the base recess, it having been previously hogged out on either one of the inside finish lathes, or on the rectification lathe, which was always available. The tools used on the recess were mounted on a square turret built on the cross slide of the lathe. The bottom of the recess was first faced off, just enough stock being left from the hogging operation to make a true and smooth finish with one cut. As the facing tool passed the centre and ceased to cut, a forming tool came into opera-

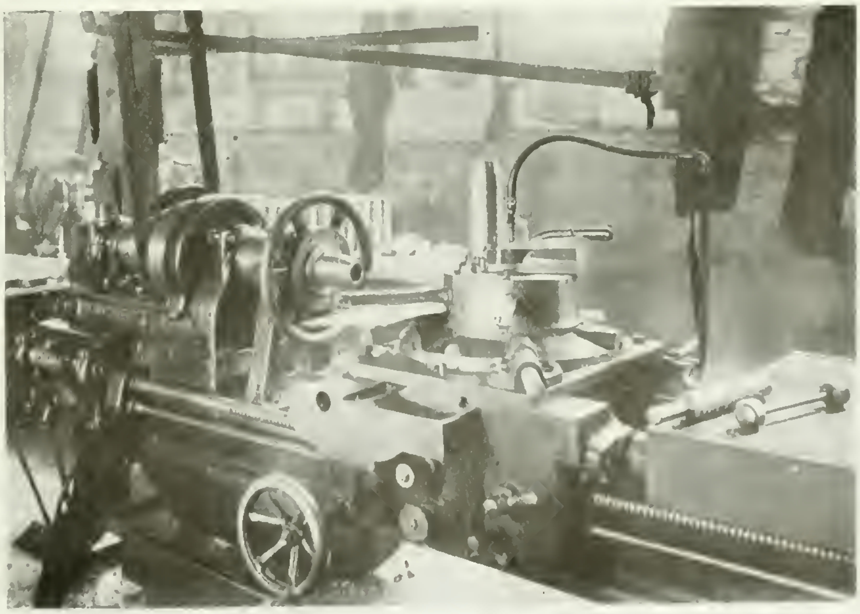

FIG. 5. INSIDE FINISHING OPERATION.

tion and put a small radius on the base end of the shell. This radius was put on for the benefit of the thread miller. It will be noticed that no work other than to remove the fracture has been done on the base of the shell. The radius, being true with the shell, assists in centralising the work in the miller. The turret was then swung a half turn, and the recess reamed to size with a flat reamer. Two sizes were made, one for the thread and one for the counterbore. The same side of the turret carried an undercutting tool by which an undercut was put in below the part to be threaded. The machine and tools used on the base recess are shown in Fig. 7, the unit being run on the open belt at a speed of 140 revolutions per minute.

A Holden Morgan thread miller was used to thread the fuse hole. These machines are so well known that a description will be omitted. After being milled the fuse hole was sized with a hand tap.

Tapping Out Base Recess

The base was tapped out on a Hoeffer Mfg. Co., 24 in. drill press, using a solid tap. The shell was held in a vise which was allowed to float on the drill press table. The tap was held in a friction holder secured to the spindle and tightened only sufficiently to drive it. A forward and reverse drive was obtained by means of an open and a crossed belt driving pulleys with a friction clutch between them. The tap, which had 10 lands 3-16 in. wide, was started into the work by the hand feed lever. Provided care was taken that not too much stock was left in the hole to be tapped, very good threads were obtained, and the operation was very quick, 350 to 375 being an ordinary eleven hours output. The shells were next thoroughly cleaned and subjected to a complete shop inspection. rectifications being made on a Boye & Emmes lathe, fitted with various convenient tools and attachments, before the shells were submitted to the Munitions Board Examiners.

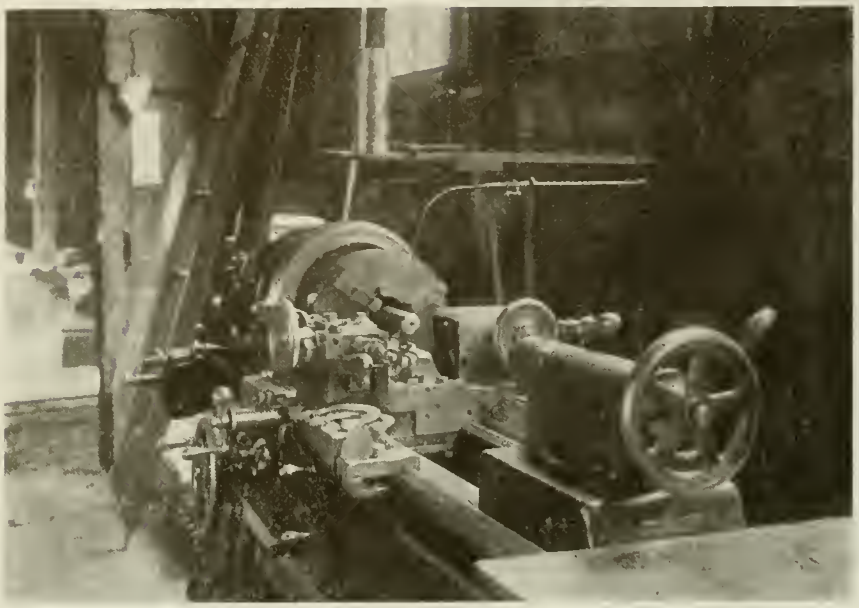

FIG. 6. COPPER BAND RECESSING EQUIPMENT.

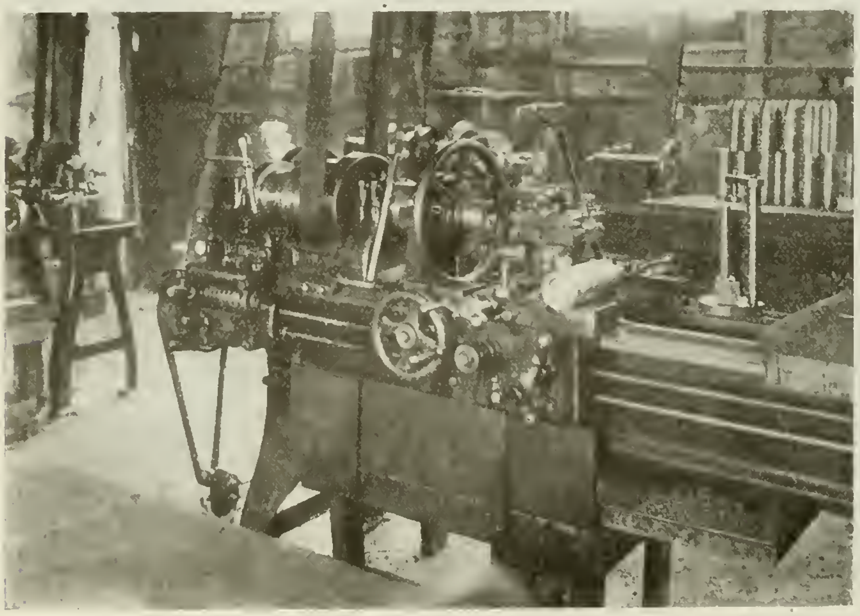

FIG. 7. BASE RECESSING OPERATION.

After passing the preliminary examination, the base plates were screwed into the shells. The base plates were machined on a 14 in. Sebastian lathe fitted with a turret on the cross slide and a screw cutting dial on the saddle. The chuck gripped the shank of the base plate and was tightened by means of a couple of cap screws. The diameter and face were first roughed off, the same tool being used for both operations. The diameter was then turned down to size with a wide tool having a projecting lip for putting a slight bevel on the face to prevent the formation of a rag. The threading tool holder carried a small wheel which, when it touched the face, located the threading tool in the correct place. Three or four cuts with the threading tool were found to be sufficient. The face of the base plate was next finished off with a flat tool set to give the required .002 in. of camber.

After the base plates were screwed in. the square shank was cut off in a hack saw. The saw had a very short stroke and two shells were put in at once, thus using up all of the blade. As previously mentioned, the blades used on the operation were those discarded at the machines cutting up the billets.

Facing Off Base to Weight

Facing off the base to weight was done on a machine built up on the bed of the rough turn lathe which was amply long enough to accommodate the two operations. The projecting portion of the base plate and a slight amount of the shell was first faced off. A side cutting tool was used which had a notch ground in it to leave a ridge at the seam. The ridge was then rolled in by three small rollers carried in a sliding block and forced against the work by the tail stock screw. The base was afterwards faced off again to remove the mark made by the rolls.

Compressed air is obtained on a large scale without employing either steam or motor-driven or other moving machinery at a copper mine in Michigan, where about 82 per cent. of the actual power of the falling water through tubes is transformed to compressed air under a pressure of 118 lb. The air is delivered to the hoisting engine, the stamp-mill power units, and to the mine proper practically dry and at the temperature of the water. The system is almost automatic, and as there are few moving parts, the upkeep is very low. Water for compression purposes is taken from the Ontonagon River, and after passing through the system is returned to it at a point about one mile down-stream. Automatic regulation is obtained by utilising the air pressure built up in the compressor chamber. Excessive air pressure is automatically relieved by means of an escape pipe running from the air chamber to the surface.

PRODUCTION METHODS AND DEVICES

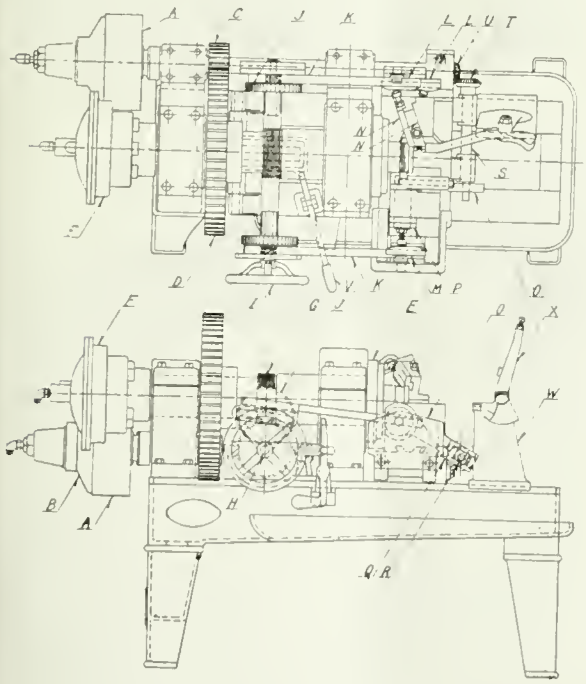
A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

INTERESTING WAVE AND GROOVE MACHINE

By R. Hamilton.

MANY interesting and ingenious devices have been designed and constructed for the operation of grooving and cutting the waved ribs on the various types and sizes of shells. The wide range of practical experience that the mechanical world has been able to put into the "game" of manufacturing munitions of war has resulted in the development of innumerable methods and attachments for the accomplishment of the many different machining operations involved in their production. Plant executives in all parts of the Dominion have, in many respects, been forced to rely upon their own resources for the success of this industry, and too much credit cannot be given those men, who through their inventive genius, have done so much in the development of suitable facilities as to make the manufacture of shells more rapid and certain.

When it is understood that the specifications call for specific results, and when on first thought it might appear that the objective could only be obtained in one or possibly a few ways, it is, to say the least, remarkable, when we learn in course that the operation is being performed in perhaps more than a score of ways, showing the different channels through which the mind of man will run even when the same identical result is required. The operation that has probably been given greater attention than any other in connection with the manufacture of shells is that of cutting the groove for the copper bands. The feature that makes this particular operation so interesting is the oscillation that is required of the tool when the waved ribs are being formed. Many methods have been adopted for the achievement of this object, the principal one now in use being that of placing a suitable cam on the face-plate for the lateral movement of the tool. The cutting tool in the majority of cases, remains stationary in relation to the axis of the shell, with the exception of its lateral and forward movement. This naturally necessitates slightly more clearance on the tools owing to their tendency to rub upon the sides of the ribs. The design of the machine illustrated was advanced for the purpose of eliminating this factor and at the same time making the entire unit practically automatic, and while the mechanism has the appearance of being rather complicated, this "grasshopper" as it is called is an extremely efficient machine.



INTERESTING WAVE AND GROOVE MACHINE.

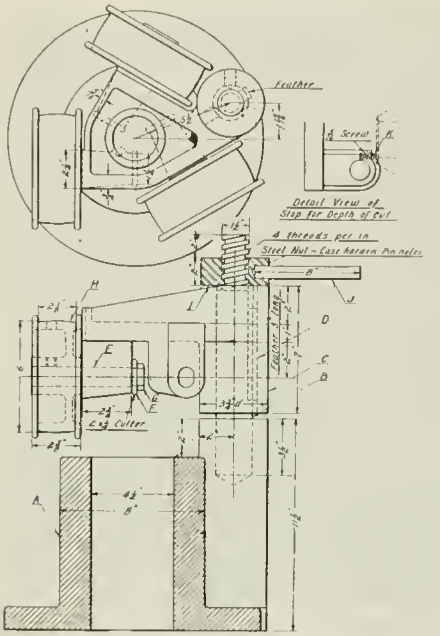
The driving pulley A is of the friction clutch type, being operated by the pneumatic cylinder B. The pinion C, keyed to the driving shaft, meshes with the larger gear D, which in turn is secured to the main spindle, the front end being provided with the collet chuck E, which is operated by the application of air in the cylinder F, located on the rear end of the spindle. Between the main bearings and integral with the spindle is the large single pitch worm G, meshing with the worm gear, directly below, on the cross shaft H, the outer end or this shaft carrying the hand wheel I, for hand manipulation. At either end of the shaft H, a small pinion is secured that drives the gears JJ, one of these being on each side of the machine. These gears are provided with a small crank that converts the circular motion of the shaft into a reciprocating one, the medium being the rods K on either side. The opposite end of these rods carries the cams that furnish the feed to the tools; the two at the back, LL, operating the undercutting tools, these being held in the two slides NN, set one above the other end at the proper angle to the axis of the shell. The cam M at the front of the machine is for the feed of the waving tool. This tool is held in the forward end of a bell crank block O, the trunnion of which fits in the tool slide, lateral play being taken up by the two lock nuts P. The outer end of the bell crank O is provided with a slot in which the small crank block is free to move. This small block fits over the crank that is turned on the end of the shaft S, the latter being driven by means of the bevel gears T and U, these in turn being secured to the end of the primary driving shaft. When the driving clutch is in, the "grasshopper" is jumping, but the feed, or the movement of the cams, can be stopped by disconnecting the worm gear from the driving worm G.

The operation is as follows: The shell is placed in the chuck and gauged to position by lowering the gauge X and turning on the air to operate the pneumatic chuck F. The lever V is then raised, and the machine commences its automatic operation. The ratio of the driving pinion to that of the main gear provides the proper oscillations for the cutting tool. With the machine running, the crank on the end of the shaft S causes a rocking motion to the bell crank O. This is one of the principal features of the complete mechanism, as the tool is always maintained in a position at right angles to the direction of the waved rib. As the shell is revolved, the cranks on either end of the shaft H slowly turn, causing the cams to move slowly back and forth, thus feeding the tools into the work. This machine has been in constant use for two years in the plant of the Jenckes Machine Co., and has given complete satisfaction.

NICKING OF SHELL NOSES

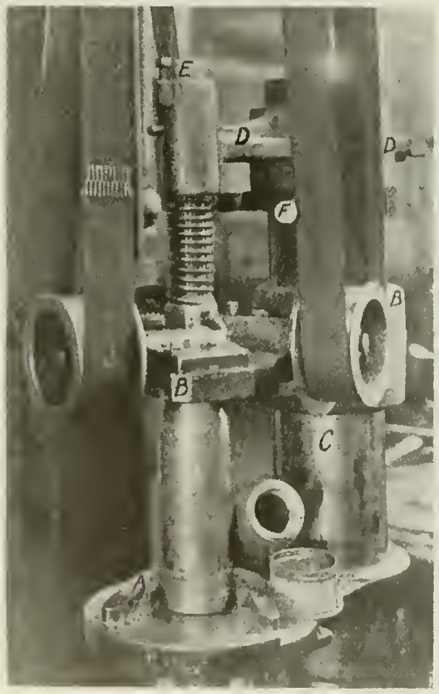
By J. H. R.

TO simplify the details of machining operations and at the same time speed up the assembling of the various sizes of shells, changes in the specifications have been made from time to time, the fulfilment of which has often necessitated new methods to achieve the desired result. One of the changes instituted during the past year has been the method of securing the fuse to fixed position after it has been screwed into place. Formerly, this was accomplished by means of small headless screws passing through the nose of the shell or socket and bearing against the thread of the fuse body. The general practice on the latest type of shell is to lock the fuse in position by burring down three points on the outer edge of the fuse platform into corresponding grooves cut at an angle in the outer edge of the shell nose bevel. This objective has been attained in different ways dependent on the initiative of the shop executives and the resources of plant equipment. The accompanying sketch shows a device constructed and use by I. Matheson & Co., of New Glasgow, N.S., and is giving very good satisfaction. The fixture is a unit in itself, being operated from a countershaft overhead. The base A, which forms the chuck for holding the shell, is firmly



NICKING SHELL NOSES.

secured to the bench, and from a boss at the back, the shaft B extends perpendicularly. Mounted on this shaft is the housing casting C that furnishes the bearings for the three cutter shafts E. To retain the three cutters in their relative position to the axis of the shell when the latter is held in the chuck, the shaft B is fitted with a feather D, permitting vertical but no horizontal movement. On the inner end of each cutter shaft is a small cutter F, which is retained in position by the nut G. These cutter shafts are driven by the small pulleys H, fitted to the outer end, the belts passing across an overhead shaft. When the shells are secured in position in the chuck, the three cutters are fed simultaneously into the nose through forcing down the housing C by revolving the nut I, which acts upon the coarse pitch screw at the top of the shaft B. A short rod J is provided for the convenience of operating this nut. The detail to the right of the illustration shows the small screw used for adjusting the depth of the cut and the point that it strikes on the nose of the shell.



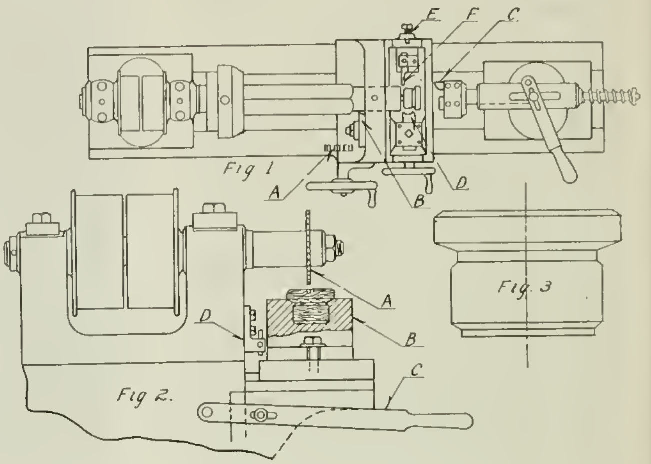
NICKING SHELL NOSES.

A similar arrangement has been designed and constructed by the Lachine Manufacturing Co., the method of operation varying a little from that shown in the accompanying sketch. The horseshoe piece A, which is fitted to the table of the fixture, gauges the location of the shell in a central position and has a vertical movement to feed the cutters into the work. The housing B is rigidly secured to the column C, and above this is secured another arm D that supports the clamping shaft E, the vertical movement of which is controlled by the stop pin shown at the front. The large spring keeps the lower end of the clamp shaft pressed over the nose of the shell, thus holding it firmly while the cutters are being fed into the work. When in the position shown, the nose of the shell is free from the cutters, so that when the shell is pushed upwards, the nose is brought into contact with the clamp before the cutters begin to cut. Small guide pulleys F are provided to assist in keeping the belts in place.

MACHINING WOOD FUSE PLUGS

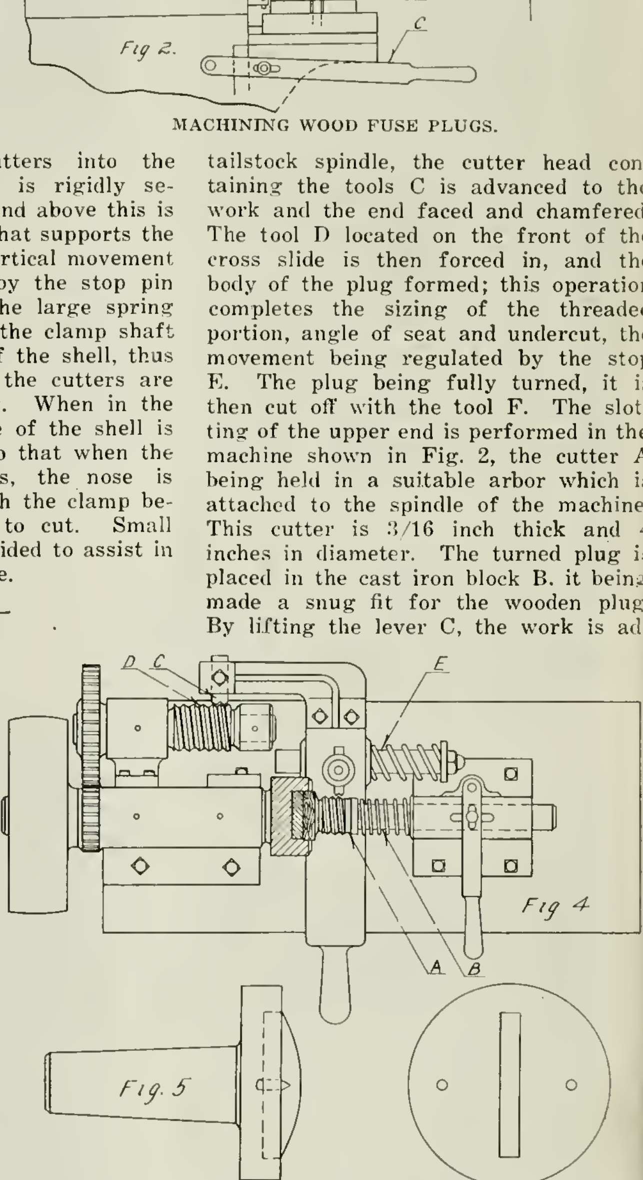
By S. B.

TO protect the noses of the shell from injury while they are being transported from one place to another, dummy plugs are placed in the threaded end; these plugs may be made from metal or wood, as their duty is only a temporary one. The line drawings herewith illustrate a special attachment for the manufacture of these wooden plugs. Fig. 1 shows the fixture used for turning the plugs from the stick. The timber is first dressed and cut into lengths 2⅝ square; one end is then turned to 2½ inches diameter so as to enter the hole in the steady head attached to the saddle. The lateral movement of the saddle containing the cutting tools is obtained by the pinion operating in the rack fitted to the bed of the machine. While moving the saddle along to the desired position, the stock is roughed from the stick by the tool B secured to the front of the steady rest. By pulling on the lever fitted to the



MACHINING WOOD FUSE PLUGS.

tailstock spindle, the cutter head containing the tools C is advanced to the work and the end faced and chamfered. The tool D located on the front of the cross slide is then forced in, and the body of the plug formed; this operation completes the sizing of the threaded portion, angle of seat and undercut, the movement being regulated by the stop E. The plug being fully turned, it is then cut off with the tool F. The slotting of the upper end is performed in the machine shown in Fig. 2, the cutter A being held in a suitable arbor which is attached to the spindle of the machine. This cutter is 3/16 inch thick and 4 inches in diameter. The turned plug is placed in the cast iron block B, it being made a snug fit for the wooden plug. By lifting the lever C, the work is ad-



MACHINING WOOD FUSE PLUGS.

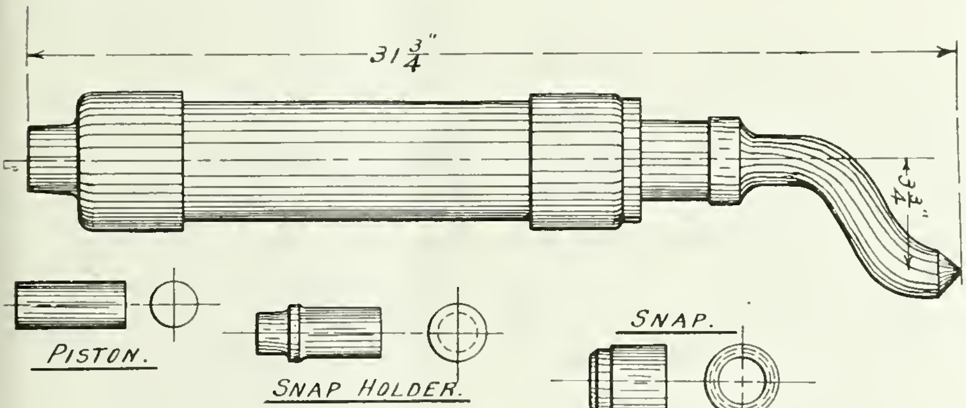
vanced to the cutter, the depth being governed by the adjustable stop located in the bracket D. Fig. 3 shows the plug ready for slotting. The machine used for threading the plugs is illustrated in Fig.

4. The plug is placed in the chuck, the driver having a projection to fit the slot in the end of the plug. It is held in position by the cup centre A which is kept forced against the end of the plug by the action of the spring fitted about the tailstock spindle B. The sketch Fig. 5 gives a clearer idea of the driving plug. By pressing down on the large handle the back end is tilted up bringing the form C in contact with the guide thread D, this latter being fitted to the auxiliary spindle at the rear of the machine. The spring on the rod E is for the purpose of returning the cutter bar to its original position after the thread has ben cut.

STAYBOLT RIVETING KINK

By S. W.

THE sketch shows an arrangement whereby the blows of a pneumatic riveter are distributed around the head of a



STAYBOLT RIVETING KINK MECHANISM.

staybolt or rivet, being riveted up in such a manner that the edges are caulked tightly down to the plate. The crank end is inserted in place of the straight centre and, as the riveting proceeds, the whole gun is rotated by the operator.

ENGINEERS AND OTHER MUNITION WORK IN THE FIELD.

AN interesting paper was read recently by C. G. Barber before the Junior Institution of Engineering on "Engineering ond Other Munition Work in the Field." He said that the workshops at the Front for the repair of equipment which may require attention, either through wear or through the effect of hostile fire, has, during this crisis, become a very important factor, because, wherever a repair can be effected at the seat of activity, considerable advantage is gained. As far as possible the most urgent repairs, such as gun and gun carriage repairs, are carried out within a few miles of the sphere of action, while some of the minor, though not unimportant, repairs are effected on the spot. It, however, falls to the lot of the base workshops to deal with the majority of repairs, and it is such that are specially referred to here. The workshops may probably employ two or three thousand hands, the majority of whom are men of H.M. Forces, and the remainder women of the town wherever the workshop chances to be pitched.

Workshop Site.

The site of the workshop, in the first place, has to be carefully chosen, with a view to speedy erection and also economy in erection. In this case an old mill was chosen, having some very useful machinery, and also most of the buildings which would be required for the different workshops. Further power being required as time advanced, was obtained by the erection of one or two engine sets of about 20 h.p. Perhaps the most important of all was the receiving department, by whom everything from the Front is taken and dispatched either to the incinerator, England, or the workshops for repair, according to the condition of the article. The unloading by the department from the trucks on the sidings is done by the French women, who are supervised by a few soldiers. In all probability these women will, for this work, will be replaced by black labor before very long.

Machine, Carpenter and Wheelers Shop

The fitting and machine shop presents nothing of very special interest, or, at least, only on some occasions, such as when carrying out some special scheme of conversion or modification to conform to suggested improvements on guns or their carriages. With few exceptions all guns and carriages which cannot be repaired up country (a few miles behind the lines), are sent home to England.

In the carpenters' and wheelers' shop all vehicles are repaired. Perhaps the most trying duties in this shop are the repair of civilian wagons, which had previously been bought by the military from farmers, when the need for such was greater than it is now. An average of forty to fifty vehicles are repaired in this shop weekly. Wheels, being standardized, are dealt with separately. The spokes and felloes are supplied from home ready cut, thus expediting the repairs. An average of 400 are repaired weekly. When the accumulation of those awaiting repairs grows above about 2,000, say, 1,000 are dispatched to England for repair.

Smoke Helmet Repair Department.

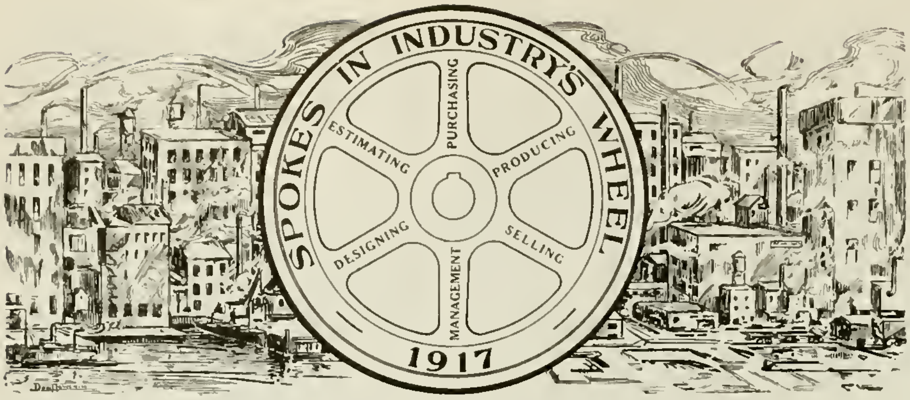
The smoke helmet repair department is responsible for the periodical redipping of the smoke helmets, which is done in specially prepared solution. Each soldier is provided with two of these helmets, one in reserve, it being the duty of the C.O. to arrange for a periodical inspection to satisfy himself that they are still effective against the poison gas. It is easy to decide. Within a few miles of the firing line it is a breach of military law to be about without one of these helmets. About 50,000 of these helmets are received from the Front weekly for re-dipping and repair as may be necessary. The eyepieces and mouth-pieces are first removed; the helmets are then washed in hot water to remove all impurities. They are then placed in centrifugal hydro-extractor to remove the excess of water, and afterwards hung in a drying cupboard, steam heated to about 180 degrees F. When sufficiently dry they are examined and repaired where necessary. Following upon this they are passed to the re-dipping plant, which is under the control of a chemical expert, who is himself responsible for the preparation of the solution in which they are dipped. The helmets are dipped and then passed through a mangle to extract the excess of solution. They are then ready for the final drying cupboard. The effect of this process is more to permeate the solution into the pores of the helmet than to dry it, and in reality the helmet leaves this cupboard in quite a moist condition. They are then ready for the assembling room where the mouthpieces and eyepieces are replaced, after which they are placed in wallets of waterproof cloth, and are then ready for dispatch to the units. The daily output of these helmets is about 6,000.

Mackintosh Cape Department

The Mackintosh cape department is responsible for the repair of capes and also ground sheets. I have sometimes seen the ground sheets being prepared for a patch the size of a dinner plate, which is applied exactly the same as a patch to a puntured cycle tire. About 6,000 of the mackintosh capes are dealt with in the course of a month, and nearly half of these are found to be beyond repair, and in some cases certainly look as though they had been in an explosion. These hopeless cases—or capes—are passed to the tent-mending department, where, including the repair of all tents, tarpaulins, etc., these old capes are cut up and utilized for the manufacture of wallets for smoke helmets, and also covers for steel shrapnel helmets.

The smoke helmets which are put aside as being beyond repair are also sent to this department, where they are cut up. Referring to the steel helmet covers, many are covered with this waterproof cloth; but, on the other hand, another favorite method of making them khaki is to paint them, and while quite wet sprinkle them with sand. This provides them with a very serviceable covering, and is more largely adopted where they are used in sandy districts.

—Practical Engineer.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

GEORGE CHADWICK GREGSON

On the seaward side of the hammer-shaped peninsula, forming part of the district of Furness, between the estuary of the Duddon and Morecambe Bay, where a narrow channel intervenes between the mainland and the long low Island of Walney, is the small but thriving town of Barrow-in-Furness. This sea town is noted for its modern and remarkable growth during the past century. The growth has been dependent primarily upon the existence of veins of pure haematite iron ore in the adjacent district. Early in the nineteenth century, mining operations were in progress, and the subsequent development was so rapid that the export of ore in 1847 amounted to 50,000 tons per year, the town at that time having a population of about 325. Some few years later, large iron works were erected, to be followed shortly thereafter by other industries. The location being a highly desirable one for shipbuilding purposes this industry soon surpassed all others, and now occupies the foremost place in the town's activities. The yard of the celebrated firm of Vickers, Ltd., is located here, and from the human element of this plant our "Spoke" for this issue received his training.

Education and Apprenticeship

George Chadwick Gregson, superintendent of the munitions department, Canadian Vickers, Ltd., Montreal, was born in Barrow-in-Furness, Lancashire, England, on December 10, 1886; his father being Robert Gregson, master mariner, and his mother Georgina Agnes Chadwick. Having come from a long line of sea-going ancestors on his father's side, it was the early ambition of our "Spoke" to cast his lot upon the briny deep, but a combination of circumstances willed it otherwise. George received his boyhood education at the High Grade School, Barrow-in-Furness, and at the age of fifteen started his apprenticeship with Vickers, Sons and Maxim, naval constructors, in the gun mounting department. The first three years were divided between bench, marking-off tables, tool and jig drawing office, and assembling of heavy guns on ships, the last two years being spent on the machines, principally lathes. Much of the success of our youthful "Spoke" is attributed to instruction given at the excellent local technical school in which the firm took special interest, encouraging the boys in every way to attend regularly. Boys who did well at the night school had their hours of work shortened, were granted bonuses, and, if so inclined, were given positions in the draughting offices.

Old Country Apprenticeship Practice

Boys of to-day apparently do not realize the difficulties contingent to the serving of an apprenticeship in British industries, and probably would not relish the early hours of rising, that is the general practice in that country. Living some distance from the works and being required to start at 6 a.m., it was necessary that our "Spoke" should "get up" at five in the morning to answer "roll call"; and to his credit be it said, that he was not late more than half a dozen times during the five years of his apprenticeship. In addition to this, George was a regular attendant at night school, two to three nights a week, acquiring the fundamental essentials in steam, machine construction and drawing, mechanics and mathematics, in order to establish himself in the theory of his practical accomplishments.

GEORGE CHADWICK GREGSON

Promotion Rapid

Honest effort is always rewarded, and a few weeks after the completion of his apprenticeship, the subject of our sketch was called into the office of Mr. Fender, works superintendent, and asked if he would like to go on his rate-paying and efficiency staff. This new departure was to the liking of our "Spoke," and for six months he was estimating and fixing prices in the Field Carriage Department, following which he was promoted to be assistant foreman in the same department. Realizing his abilities, the management transferred him to the shipyard, where for twelve months he was engaged in fixing prices and looking after costs on all ship fittings. Similar positions were filled in the Marine Engine Department, fixing prices on all classes of machinery; the same duties in the large turbine erecting pits, and at the same time looking after the cylinder and shafting shops. During his sojourn in this latter department, the engines of the large battle cruisers, Lion and Princess Royal, were under construction, these consisting of turbines developing 75,000 horse-power; also those for the Japanese battle cruiser, Kongo, of 80,-000 rated horse-power. Trouble having arisen in connection with the maintenance of the heavy oil engine department, our "Spoke" received instructions to establish order there, as a result of which he gained further new and interesting experience. During the seven years that followed his apprenticeship, he covered all the machining and assembling sections of the works, which at that time was employing from 18,000 to 20,000 men, and which has justly earned the reputation of having the most satisfactory and complete cost and process system in the world; that is, for a plant of its size and character. A constant source of inspiration to the members of the rate fixing staff was the opportunity given to study the editorial contents of various trade and technical periodicals, the firm supplying these, as a result of which tool and jig design were in many cases materially influenced.

Accepts Position in Canada

While still in the heavy oil engine department, our "Spoke" was approached by the Ingersoll-Rand Co., of Sherbrooke, Que., with a view to accepting a position to assist in establishing a planning and efficiency department. Negotiations being satisfactorily arranged, G. C. G. came to Canada in the spring of 1913 and spent two pleasant and instructive years, the experience gained being of inestimable value. In March of 1915, our "Spoke" again returned to Vickers' employ, this time, however, to the Canadian plant at Montreal, P.Q. At this time the manufacture of munitions was occupying the attention of many Canadian industries, and our "Spoke" was given the position of superintendent of a shell shop which was just being inaugurated. Much of the success of Canadian Vickers, Ltd., during the past two years of shell activity can be credited to the untiring efforts and executive ability of Mr. Gregson, although he admits that he has thought, many a time, that his friends would be visiting him in Verdun. (There is a place there where the guards do your thinking, and entertainment is supplied by the Government.)

Travel, Recreation, and Social Side

Whether G. C. G. is a believer in the adage that "A Rolling Stone Gathers no Moss," is not known, but at any rate his traveling has been confined to a few trips to the States on the lookout for machinery. However, the call of his forefathers is still heard, and during his summer holidays, particularly before coming to Canada, he spent his recreation periods upon the deep blue sea. He remembers with pleasure that a few years back he used to pack his "sea bag," go over to Fleetwood, and ask some trawler skipper if he would take a passenger, the answer generally being favorable to our "sailor's" ambition. Many a two weeks were spent in this way, either on the South Coast of Ireland or to the lonely rock of Rockwell, on the West Coast of Scotland. Being an Englishman, G. C. G. is also passionately fond of walking, and in pursuit of pleasure he has walked over many portions of England, Ireland and Wales.

Early in 1914, eleven months after his arrival in Sherbrooke, P.Q., Mr. Gregson married Mary Constance Vernon, youngest daughter of Mr. and Mrs. J. W. Vernon, of London street, Sherbrooke. George's wife is a Canadian, and a great booster for this country, her mother's name being Bliss, and one of an old Eastern Townships family. The present residence of our "Spoke" is at No. 22 Third Ave., Montreal, about three minutes' walk from the plant; this feature during the past two years proving especially handy when it is necessary to be called to the works at all hours of the day and night.

Views on Technical Study

In religion, Mr. Gregson is an Anglican, and in politics (English), was a Liberal; but the strenuous times of the past few years has given little opportunity to declare himself in this country. Mr. Gregson, when time permits, uses his recreation hours in cricket, football, tennis, and fishing.

Speaking of the advantages of technical study on the part of young mechanics, Mr. Gregson says: "In my opinion, the technical papers have, and are, playing a very important part in the development of the modern machine shop; in their pages one sees all that is new; you are brought into contact with what is going on in other shops throughout the country. Many and many a time we have just got the idea we wanted by running through a bundle of technical papers in search of a simple jig, or inexpensive and quick production tool. The idea of a jig and tool designing office without these journals is too ridiculous to think of. If the young mechanic of to-day has any ambition outside of being just a good mechinist, he has simply got to study, and study hard. These are days of keen competition, and the man who has a little more knowledge than his fellow, and the ability to use it, is the one to gather the plums."

BRITAIN'S ORE AND PIG IRON SUPPLY

DISCUSSING Great Britain's supplies of iron ore and pig iron, also the shipping situation in general, Premier Lloyd George said:—"We are melting millions of tons every year of iron ore, and we cannot cut down the supply by a single ton. It is essential for the munitions of war, essential for shipbuilding, and essential for the machinery required in agricultural work. Therefore, we must find ships for this work at all costs. There is plenty of ore in the country, but its quality is not too good, and it has not paid to dig it. It has been cheaper to get the better class of ore from Spain.

"This, however, is not a commercial question. It is a question of getting ore, and getting it without using up our shipping tonnage. It involves, unfortunately, the increasing of our number of blast furnaces. That means more labor for building and carrying on the work, and there is a very limited supply; in fact, there is no margin of supply of highly skilled men to work these blast furnaces. We have protected them against recruiting for months, but in spite of that fact, we are short of the necessary supply of labor for our blast furnaces.

"There are mines in Lincolnshire, in Cumberland, and there are the famous Cleveland mines, all producing excellent ore; and if we could increase the labor in those mines we could augment by millions of tons a year the quantity of ore which can be produced at home. Here, again, you require skilled as well as unskilled labor. I want to make a special appeal to both classes. There are a certain number of mines which might be able to spare a few miners for this purpose. In those two directions we might be able to secure the necessary number of skilled men, and for the unskilled men we must trust the people to place their services at the disposal of Neville Chamberlain for the purpose of assisting in this all-important task."

As to the supply of pig iron, the secretary of the Cleveland Blastfurnacemen's Association stated some time ago that during the past six months six additional furnaces have been put into operation in the Cleveland district, which should mean an increase of between 4,000 and 5,000 tons of pig iron weekly. The work at the seventy-six furnaces now in blast is being carried on with the minimum number of men. Before additional furnaces could be put to work the skilled men necessary must be relieved from military service.

The Barrow Steel Co. has had a furnace waiting for several weeks to be put into operation, and the Askam Ironworks is ready to start when a regular supply of ore is assured.

PRESERVE FIELD PRODUCTS FROM LOSS BY FIRE

THE fire waste of the Province of Ontario for the first three months of 1917 as shown by reports to the Fire Marshal, amounts to \$3,321,931. In 1916 it amounted in round figures to \$12,000,000, and if the waste is not stopped, the year 1917 threatens to be as disastrous as its predecessor. The unfortunate part of the whole matter is that the waste comes largely from the destruction of field products in barns, elevators, and warehouses, or in canning factories, cereal mills, and other places where the raw product is being turned into food for our own needs and for the armies of the Allies It is equally true that many fires, probably one half of them, could be avoided by a little care and thought. Surely, as a people we should be ready and willing to take up this Empire call and preserve what we produce.

By way of example, reference is made to barn fires. Last year, in Ontario alone, over 600 barns were destroyed, involving a loss of more than one million dollars, of which six hundred thousand dollars was on produce, implements, and live stock. If by a little care we can save one half this loss we should be doing the equivalent of that much extra production, and who is there among us who is not prepared to do his "bit" on this line? Three very simple suggestions are thrown out which if adopted will go a long way to accomplish the result:—

1.—Install lighting rods on barns and save fires from lightning. The Department of Agriculture, Parliament Buildings, Toronto, will furnish any one with a pamphlet showing how the rods should be made and erected. It is an absolute fact that barns properly rodded and grounded are not liable to be struck by lightning.

2.—The crops should not be put in until it is certain they have been properly cured. Evidence is daily accumulating that the heavy clover crops of last year did not receive full and proper care and resulted in the firing of barns from spontaneous combustion. Many doubt this theory but recognition of the cause is growing very rapidly.

3.—Ventilate the barn so that gases caused by the fermentation of imperfectly cured crops will be successfully carried off. In an unventilated barn to keep the doors and windows closed after harvest, and then admit air by the opening of the doors, windows, or other apertures during the warm fall weather is to invite the fire fiend to get in his work.

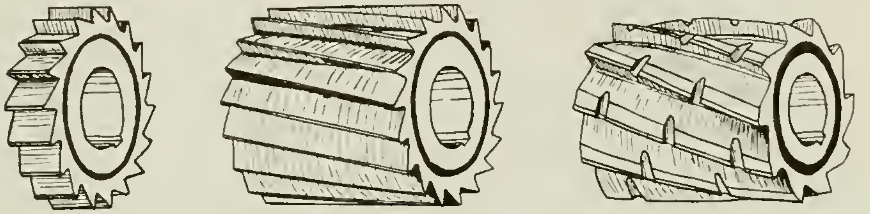
MACHINISTS' INSTRUCTION COURSE—XX.

By J. Davies.

THE most common cutter used in milling machines is the plain miller, sometimes called cylindrical. It is simply a plain, round cutter with teeth cut straight across, see A, Fig. 72; it is a cheap cutter to make and answers very well for milling narrow surfaces. It is not very suitable for milling wide surfaces, however, because the full length of the cutting edge comes in contact with the work at one time. This has led to the construction of milling cutters with helical teeth, see B. Fig. 72. In a cutter of this kind the cut commences at one end of the cutting edge and gradually works across the full width, which prolongs the life of the cutter, makes a smooth job, and takes less power to drive.



A B C

FIG. 72.

Far very heavy milling on extra wide surfaces, a cutter with helical teeth is used, the teeth being so nicked that a cutting edge comes behind each nick so that it does not affect the finished surface. The nicking of the teeth causes the chip to be broken up, enabling a heavier cut to be taken than would be possible with the ordinary milling cutter, see C. Fig. 72.

Inserted Tooth Cutters.

Owing to the high cost of tool steel, every benefit that can be obtained by the use of inserted teeth, or built-up cutters, ought to be taken advantage of. Not only is the saving due to the reduced cost of the steel, but also in the convenience of manufacture and handling, replacing of broken teeth, and better results in hardening. There is quite a variety of designs of inserted teeth milling cutters, some people preferring one kind and some another. Three typical designs are shown in Fig. 73. In A, the body is made preferably of machinery steel, although wrought iron or even cast iron is sometimes used. The hardened tool steel teeth are held in place by taper plates or bushings and screws, and can thus be easily adjusted or removed. The bushings, screws and teeth are interchangeable. The second, B, differs from the first only in the method of securing the inserted blades. A hole is drilled between every blade and reamed out taper to suit a standard taper pin, and after reaming, slots are cut through the reamed holes. The taper pins are driven into the holes expanding the metal, which secures the blades very effectually. The third type, C, is another variation of the same idea, only in this case taper dovetailed keys are fitted into the slots milled to receive them. This makes a particularly solid cutter, and by tapering the ends of the blades and fixing them to project past the body of the cutter a good side-cutting miller can be made.

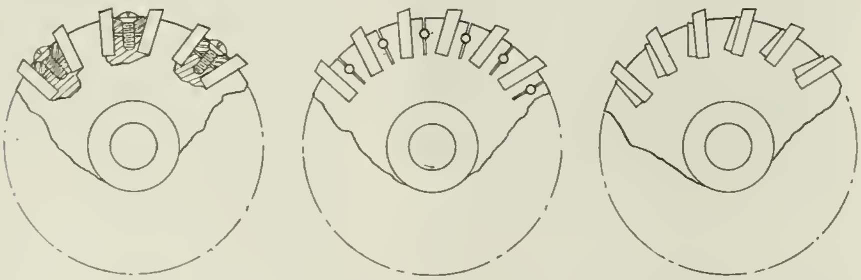


FIG. 73

For milling tee-slots and dovetails, a solid end mill is generally used with a taper shank which is driven tight into the spindle of the machine. See Fig. 74. In driving, care must be taken not to break the teeth; use a lead hammer, if possible, or, if not, drive with a piece of hard wood. In any case be sure that the taper of the shank fits the spindle and that it is driven home good and snug.

Holding and Setting Cutters.

In some milling attachments extra precautions are taken to keep the end mills from coming loose. Sometimes they are drilled and tapped at the end to receive the spindle and are thus kept in place; or perhaps a taper pin passes right through, or a safety set-screw. No matter how it is done, be sure to keep it tight. If being used on a repetition job, it is an easy matter to make some sort of a jig or fixture to hold the work; in like manner, special cutters are made for nearly every conceivable kind of a job.

Setting the cutters is a problem that is worth some consideration. It is not often that a cutter can be set for depth by direct measurement, and the guess and try method is very unsatisfactory. The most practical method is by using the indicator dials attached to the feed screws, which are usually graduated in thousandths.

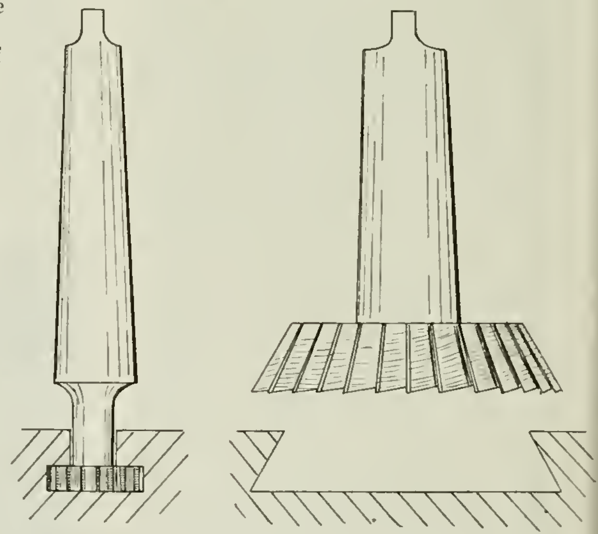

FIG. 74.

When setting the cutter by use of the graduations, bring the work and cutter together close to each other, and start up the machine, in case the cutter may not be turning perfectly true, as a cutter that is not running true will cut deeper than a true one of the same diameter, if set to the same mark. Bring the work up to the cutter until it just touches, and be sure that all the lost motion, or back lash, as it is also called, is taken out of the feed screw before the cutter touches the work.

When the cutter is just touching the work, a reading of the indicator is taken, and the work run clear of the cutter.

Add the amount equal to the depth of the cut required and set the machine accordingly.

If the nature of the work will permit the trying of a gauge or testing with micrometers, test as soon as enough finished surface is milled to permit of doing so. It will be found that in most cases a little more will have to be taken off on account of the spring of work and cutter. The graduations are very useful at this stage, as the table can be raised just the amount required as found out by careful measurement.

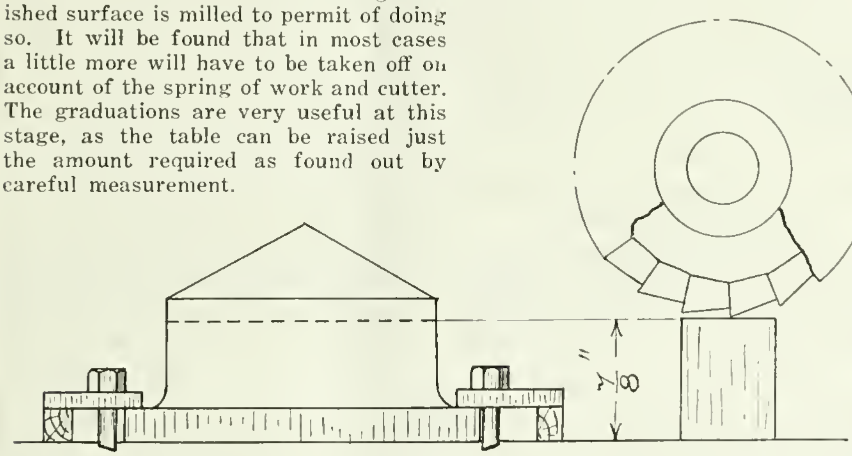

FIG. 75.

Use of Tool-Setting Blocks.

In some cases a measurement must be taken at a given distance from the base as shown in Fig. 75. The tool-setting blocks as used on the planer can be used on a job like this. Then again bring the work and cutter together until the cutter is just touching. If it is found that the cutter is not running perfectly true, stop the machine with the tooth of the cutter that touches the work next to the table, run the cutter clear of the work and raise the table high enough to take out all lost motion. Now lower until the gauge just touches the cutter as it passes underneath. Always stop the machine when setting the cutter this way, as milling machine cutters are no respecters of fingers.

An adjustable gauge can easily be made for this class of work and set to the required size by micrometers. If you have no tooth-setting gauge and do not think it worth while to make one, one can be made in a few minutes by taking a piece of ½-sq. stock cut off with a hack-saw and ground to size—a pair of inside calipers can be used, or else a surface gauge. In using calipers, find the shortest possible measurement between the cutter and the table, and adjust to size. If the machine has no graduated dial or indicator, and you have to make a cut of a given depth, the small adjustable tool-setting block shown in Fig. 76, is very useful in setting up the cutter as just described. Run the cutter clear of the work, adjust the gauge block to just touch the cutter. Measure with calipers or micrometer, deduct the amount of cut required and reset the cutter to the gauge block. A very short adjustable gauge is all that is necessary as parallel blocks can be used to make up the height.

The milling machine differs from the lathe and planer, inasmuch as the work on the miller in most cases must be set correctly before the cut is put on, or the job may be spoiled.

Setting the Cutter Sideways.

Hrere again the graduations on the feed screw can be used to advantage in setting the cutter to cut at any given distance from the edge of work held in the vise. If the work stands up above the top of the vise, place the edge of the cutter against the edge of the work, note the graduations and move

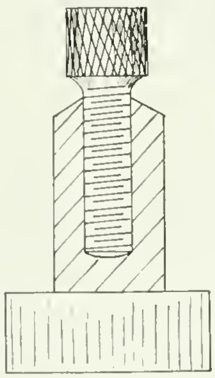

FIG. 76.

the work over the amount required, being sure to take into consideration the thickness of the cutter. See Fig. 77, left.

If the work is below the vise, or if there is room at the end of the vise, bring the cutter up against one side of the

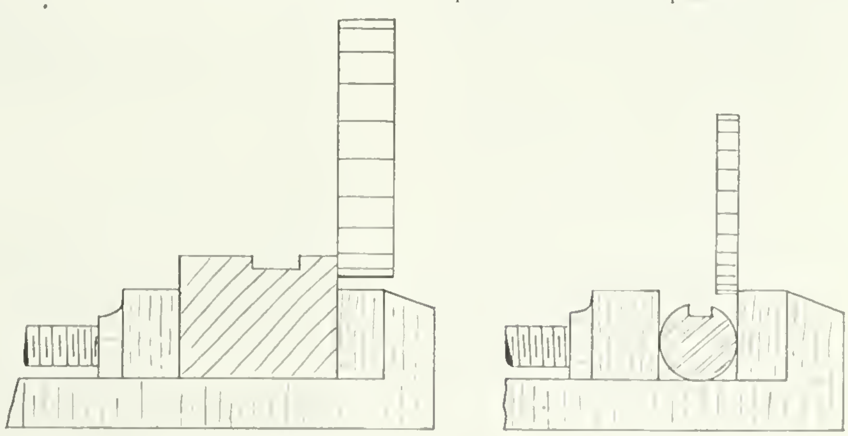

FIG. 77.

vise, Fig. 77, right, and run it over to the other side, noting the distance on the indicator. Then bring it back half the distance to the centre of the vise. If there is any lost motion in the screw, take it out before counting the graduations either way, or else caliper with a pair of inside calipers equal distances from both sides of the cutter to vise jaws, when cutter will be in centre

CALCULATING THE WEIGHT OF A FLYWHEEL

By D. A. Hampson.

THE weight of a flywheel needed for a machine which does all of its "work" during only a portion of its cycle can be determined by well-known formulae if certain assumptions are made and if the work can be expressed in foot-pounds. The most familiar machines requiring flywheels to balance work of this sort are punches and presses for sheet metal working. With these the work is done during a portion—say from one-tenth to one-half of the downward stroke; the remainder and all of the upward or return stroke are idle movements, simply overcoming the friction of the machine. As the belt is constantly running, it is the function of the flywheel to store up enough energy during the idle portion to overcome the resistance of the working portion of each revolution.

The first step in the calculations is to put that resistance in terms of foot-pounds; then to find just what is the proportion of idle to useful time. This is usually a matter of measurement and is reduced to degrees about the flyweel centre, for instance—20 degrees working, 340 degrees idle. If the number of revolutions per minute of the flywheel is known, this is again reduced and expressed as "seconds working," "seconds idle." If the speed is not known, one must be assumed for calculating purposes.

There must also be known, or assumed, the reduction in speed which the flywheel makes during the working period. This is an important factor and in the case of a new machine must be assumed, basing the assumption on experience and judgment—it is commonly stated as "per cent. loss in speed while actually cutting." In the case of cutting, say a thin sheet of brass the loss will be perhaps only 5 per cent. or less; if the length of the cut in the direction of the stroke is considerable, the loss may run high, perhaps 25 per cent.

Example of Application

Paper cutting machines are fine examples of the case where the length of the cut is a major part of the stroke. The vertical travel of the cutting knife may be 5 in. and for this size of machine the capacity would be at least 4½ in. of paper. This is many times the proportion found in machines for stamping sheet metal and furnishes a very interesting example for flywheel design. It is obvious that either a very heavy flywheel must be provided or else there will be a big reduction in speed when cutting, for if the wheel is not heavy enough, the machine will run slower and slower as the knife cuts downward and may even stop if the flywheel cannot give up energy enough to carry past the lowest point. A special paper cutter, built on much the same lines as an open side punch press, furnished a problem which the following calculations successfully solved: The data determined and assumed were as follows:—

1,050 lbs. pressure required back of the knife to do the cutting.

3 in.=stroke of press.

2 in.=1/6 ft.=length of cut in direction of stroke.

60 rev. per min.=60 cutting strokes per min.

Cut=110 deg. or .3 sec., idle=250 deg. or .7 sec.

18 in.=1½ ft.=mean diameter of flywheel rim.

Total energy required for the cutting stroke=1050÷6=175 ft. lbs.

The following formulae are now applied.

$$(1)\ \text{H. P.} = \frac{\text{ft. lbs. reqd.} \times \text{rev. per mm.}}{33{,}000} =$$

$$\frac{175 \times 60}{33{,}000} = 32.$$

$$(2).\ E_1 = \text{ft. lbs. reqd.} \times \left(1 - \frac{\text{sec. of actual cut}}{\text{total time of stroke}}\right) =$$

$$175\left(1 - \frac{.3}{1}\right) = 122\tfrac{1}{2}\ \text{ft. lbs.}$$

$$(3).\ \text{Wt.} = \frac{E_1}{\text{constant} \times \text{dia.}^2 \times \text{rev. per min}^2} =$$

$$\frac{122\tfrac{1}{2}}{.0000118 \times 1.5^2 \times 60^2} = 1281.$$

The constant in the denominator of (3) varies from .000002 for 2¼ per cent. loss to 000015 for 20 per cent. loss.

Formula (1) is not necessary to the flywheel calculation but gives an idea of the work to be done and the sizes of belt or motor needed. After the weight is found, the section of the rim necessary is a matter of adjusting width and thickness to othre conditions. The entire calculation is free from complication and answers for all simple cases.

THE METRIC SYSTEM AND POST-WAR DEVELOPMENT

By J. Hardie.

IN view of the possibility of extended inter-continental commerce between countries and Canada, it will probably be necessary for the industrial world to become better acquainted with the standards of measurement now in use in European and South American countries—namely, the metric system. This system is based on the theory of the metre being 1-ten millionth of the quadrant of the earth's surface, on a line passing through Dunkirk. The unit of volume is a cube measuring 1-10th of a metre on a side, and is termed a litre, while the gram is the unit of weight and is nominally 1-1,000th of the weight of a litre of water at 4 degrees Centigrade, or 32.9 degrees F.

The origin of the system dates back to the seventeenth century, when the French astronomer, Jean Picard, proposed to take as a unit of measurement the length of a pendulum, beating one second, at sea level, at a latitude of 45 degrees. Nothing definite was accomplished, however, until the year 1790, when the National Assembly appointed a commission to investigate the advisability of establishing a system of measurements, based on the theory of Picard. The decision of the commission was in favor of using as a base the quadrant of the terrestrial meridian, but it was not until 1799, after nine years of investigation and calculation, that the length of the metre became a fixed value. The new system became "compulsory" in 1801. Other systems were still in use in many parts of France, and in an effort to extend the adoption of the National system it was necessary to pass a law in 1837, forbidding the use of any other weights and measures than those established by the law of 1799.

Legalized in Many Countries

The metric system is now obligatory in the following countries:—Argentina, Austria-Hungary, Belgium, Brazil, Chile, France, Germany, Greece, Italy, Mexico, Netherlands, Norway, Peru, Portugal, Roumania, Servia, Spain, Sweden, and Switzerland. Its use is legalized in Egypt, Great Britain, Japan, Russia, Turkey, and the United States. In England, several attempts have been made to have this system supersede that at present in vogue, but without success. However, in 1897 certain concessions were

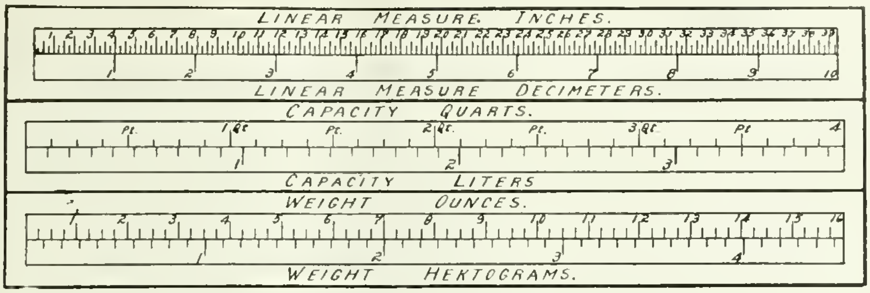
granted and a statute was passed, the Weights and Measures (Metric System) Act, legalizing the use in trade, of the metric system, and abolishing the penalty for using or having in one's possession, a weight or measure of that system. The metric system was legalized in the United States in 1866 and the recognized value of the meter is 39.37 inches.

However, despite the efforts of the many foreign countries to suppress all other forms of measurements, it is an unquestionable fact that the metric system has not entirely supplanted those methods previously in use; on the contrary, while the metric system is generally recognized as the official Government standard, certain industries and merchants continue to designate in lignes (0.089 inch) and inches all the articles they sell. Many countries in Western Europe "sell" their product by the metric system, but make use of the old system in the process of manufacture. In France and Belgium manufacturers of silk fabrics make exclusive use of the Aune (1.312 yards) and the Denaro (18.17 grains) as the units of length and weight respectively. In Germany, the cotton industry is based on the British yard and pound, and the woollen industry on the old German ell (27.08 inches) and pound. Throughout the metric and non-metric world, lumber is sawn by the inch.

With the above facts in mind, it would appear that the metric system has apparently not yet developed sufficient advantages to justify its general adoption; even by those countries whose Governments have made it a penal offence to use any other system. The advocated feature of the system seems to be the convenience of reduction or conversion of the units, due to its decimal divisions. The importance of this factor, however, is lost in the knowledge that such conversion, for practical purposes, is very infrequently used. In the everyday requirements of industrial and commercial activity, the fundamental principles of any system of measurements is to weigh and measure, not calculate. Nevertheless, in view of new developments that will undoubtedly arise at the termination of the war, a clearer understanding as to the comparative values of the British and metric system may be of inestimable value in the near future, and to assist readers in this matter, the accompanying tables and conversion constants have been prepared:



Derivation of Nomenclature

Multiples in the metric system of measurement are derived by prefixing the Greek words deka (10), hekto (100), and kilo (1,000). Divisions are obtained by prefixing the Latin words deci (1/10), centi (1/100), and milli (1/1000). The measurements of surfaces (areas other than land) and volumes are obtained by squaring or cubing the values in the linear table, similar to the English method; for instance, a square centimetre would be 10mm. x 10mm equals 100 sq. mm., a square metre would be 10dm. x 10dm. equals 100 sq. dm. The same principle is applied to volume; thus, 10dm. x 10dm. x dm. equals 1000 cu. dm. equals 1 cu. m. In the measurement of capacity the litre is the unit, and is equivalent to the volume occupied by one cubic decimetre; the corresponding English value being 3.937 x 3.937 x 3.937 equals 61.023 cu. in. nearly. The U. S. gallon contains 231 cu. in.; therefore, the litre is approximately .265 of a gallon, or 2⅛ pints.

The accompanying tables, together with the chart and conversion constants, provide a convenient reference to compare the relative values of the metric and English systems. To illustrate the value of the conversion tables, take for example, to translate the expression \$1 per foot into francs per metre. One dollar per foot would be \$1 multiplied by 3.281 equals \$3.281 per metre, as the franc (19 cents) is the unit of the monetary system in France, also the adjacent countries of Belgium and Switzerland, the French value would be 328.1 divided by 19, equalling 17.26 francs per metre.

STRATEGIC VALUE OF CAPE BRETON ISLAND*

By F. W. Gray**

WHEN the French monarchs of the old regime selected Louisburg as the site of an impregnable fortress, proudly named the "Dunkirk of America," they had a proper conception of the strategic importance of the ISLE ROYALE, that outpost of Canada since known as Cape Breton Island. Who holds the Island of Cape Breton commands the Cabot Straits and the Gulf of St. Lawrence, and if that same power holds also the island of Newfoundland, the Gulf of St. Lawrence can be made a closed sea.

While the main ideas of naval strategy are the same in all times, yet to-day we think in terms of modern inventions. The advantages given to Cape Breton Island by its geographical positions are at this date enhanced by the presence of large bodies of coal developed to a producing stage, by the existence of large iron and steel works and chemical plants, and by the existence in connection with these industries of commodious harbors, equipped with facilities for loading and discharging cargoes, and by rail connection with the mainland.

The Coal Factor

It may be laid down as an axiom that no modern nation can retain economic independence unless it possesses within its frontiers a supply of bituminous coal. Bituminous coal is the motive power of modern civilization. It has been truly said—and by a German military leader—that victory in the present war will go to the nation that can mine and carbonize the largest quantity of bituminous coal. No form of deep mining can be prosecuted without coal, and the absence of coal will effectually limit the mining of all metals and minerals. Coal moreover is the source of the base of the most destructive modern explosives. Briefly, without coal the national armament would be limited to the weapons of the mediaeval knight. As this war and its preliminaries have abundantly demonstrated, economic dependence spells sooner or later political subservience.

The importance of Cape Breton Island is chiefly this: With the exception of a strictly limited deposit of bituminous coal on the mainland of Nova Scotia, the Island of Cape Breton and the submarine territory adjacent, contains the only supply of bituminous coal in Canada east of the region of Weyburn and Estevan.

Coal Spells Power

The national future of Canada, its maintenance of national integrity and political independence, is bound up with retention of possession of the coalfields of Cape Breton Island. This may seem a sweeping statement, originating in the mind of one who attaches undue importance to coal, but a little consideration of the present position of France, Italy, Switzerland, Norway, Sweden, Spain, Greece, and—to come nearer home—of Central Canada, will show that the statement is made advisedly. France and Italy would be impotent and defeated if it were not for the coalfields of Britain and the British Navy.

The position of the European neutrals to-day is dictated by the source of their coal supply. The safety of the United States lies not so much in vast territory and population as in the possession of the richest coalfields of the world, so situated as to be far removed from the danger of foreign invasion. If Russia were not the possessor of coalfields she would be more helpless than Holland, more dependent than Denmark, because, and here is where the analogy interests Canadians, extent of territory, density of population and agricultural wealth are a menace only, if coal is absent. In these times coal spells power. It is a necessity of nationhood.

Is it therefore too much to say that if Canada wishes to fulfil the glorious promise of her future she must guard as a precious jewel that remote Island which saw the dawning of British power and British ideals on this Continent, and stands not only as a sentinel over the broad and ancient commercial highway of the St. Lawrence, but is Canada's chief treasure house and depository of coal, a substance greater in potentialities than all the silver of Cobalt, or all the gold of Porcupine and Yukon.

As the principal British naval base in North Atlantic waters, Halifax will always retain its pre-eminence, and it only needed the actual stress of warfare to restore to this Canadian port the lustre that had become dimmed by a long period of peace. It is an ice-free port, lending itself admirably to fortification and submarine defences, and its railway connections would be difficult for a hostile landing force to interfere with so far as the immediate hinterland is concerned. Of the two lines of railway that connect Halifax with Quebec and Montreal, one parallels the St. Lawrence river so closely as to be quite open to attack from the river, and the lower gulf. The capture of Halifax by hostile forces would not so seriously impair our national defences as would the hostile occupation of Cape Breton Island. Those who have followed the course of events at Zeebrugge, on the Belgian coast, will realize what the Bras d'Or Lakes could be made as a submarine base if they fell into the hands of an enemy, and the analogy between the Dardanelles and the Straits of Canso must have struck every military observer who has ever passed through the narrow channel dominated by the imposing bulk of Cape Porcupine.

Comparative Strategic Value

Imagine a geographical position which combines the strategic value of the Dardanelles and Gibraltar with the industrial importance of Pittsburg or Sheffield, and one has a fair and not exaggerated conception of what Cape Breton Island means to Canada, and conversely, one may deduce what nature the menace would assume were this island in enemy hands.

The potentialities of Cape Breton Islan for defence or for offence in the hands of a resourceful foe, are less or greater according to the smaller or larger concentration of industrial activities in the island, and the time seems to have arrived when the Government of Canada must take this matter under consideration in all that bears on the future of industrial expansion in Cape Breton.

Take for example the suitability of Sydney Harbor for a shipbuilding plant. The advantages of this site are too obvious to necessitate their being set out in detail; the thing is self evident. A large ship-building industry in Sydney, with the provision of the dry-dock that would be a natural and necessary accompani-

*Paper read at recent annual meeting of Mining Society of Nova Scotia.

**Asst. to Gen. Mgr. Dominion Steel Corporation, Sydney, N.S.

ment, connotes at once adequate military and naval protection. Otherwise it will be foolish to multiply and concentrate still additional facilities in Cape Breton Island that would advantage an enemy in control of the island.

ANNUAL MEETING OF MINING SOCIETY OF NOVA SCOTIA

THE twenty-fifth annual meeting of the Mining Society of Nova Scotia was held at the Sydney headquarters on April 19, and was attended by about seventy-five members. The morning was occupied by a visit to the works of the Dominion Iron & Steel Co., in which the whole process of steel manufacture was followed from the ore-bins to the finished product. In the afternoon the business of the society and the reading of papers was proceeded with. The report of the treasurer showed a satisfactory condition of the society's finances. The officers of the society for 1917 were elected as follows, the election of the president, vice-president and secretary-treasurer being by acclamation:

President, Hon. Col. D. H. McDougall; vice-president, Hon. Col. Thomas Cantley; secretary-treasurer, E. C. Hanrahan; associate-secretary, E. A. Saunders.

Members of Council: F. J. Sexton, T. J. Brown, J. R. McIsaac, Hon. Robt. Drummond, F. E. Lucas, H. B. Gillis, Alex. McEachren, G. D. MacDougall, Malcolm Beaton, W. H. Graham, Malcolm Blue, F. W. Gray, C. M. Odell, John Casey, R. E. Chambers, Isaac Greenwell, John Johnson. The list of papers presented is as follows:

John Casey.—"Safety and Mine Discipline."

W. H. Graham.—"Some Notes on the Advantages of Efficient Coal Washing as Reflected in the Manufacture of Iron and Steel."

F. W. Gray—"The Strategic Value of Cape Breton Island, With Especial Reference to the Coal Fields."

Vincent McFadden—"A proposal for the Complete Electrification of the Industries and Transportation of Cape Breton Island."

Geo. D. MacDougall—"Modern Steel Plant Economics."

C. M. Odell—Title to be announced.

Robert Robertson—"Sinking of the Jubilee Shaft, Sydney Mines."

Prof. F. H. Sexton—"Vocational Training for the Crippled Soldier."

A. J. Tonge—"Mine Fires. Their Origin, Control and Extinction."

As the business of the meeting was confined to one afternoon session there was not time to read and discuss the whole of the papers. The papers will, however, appear in the society's transactions, and it was decided by the meeting that all the papers should be open for discussion at the next annual meeting, which, it is hoped if war conditions will permit, will resume the customary form of a two days' meeting with the annual dinner.

On the recommendation of the Executive the meeting appropriated the sum of $100 to the "Belgian Kiddies Fund" of which E. P. Mathewson of Toronto is the chief sponsor for Canada. The meeting was actuated in its selection of the "Belgian Kiddies Fund" by a desire to honor H. C. Hoover. As a leading member of the mining profession, Mr. Hoover's record during the war has been one which reflects lustre on the profession, and the fact that he is a citizen of our latest ally is fully appreciated.

A select committee composed of Messrs. T. J. Brown, G. D. MacDougall, Prof. F. H. Sexton, and F. W. Gray was named to look into and report on the possibility of finding some satisfactory basis of federation or affiliation with the Canadian Mining Institute.

The meeting moved that there be recorded in the society's transactions a resolution setting forth the unanimous appreciation of all the members of the society of the patriotism and self-sacrifice of the miners of Nova Scotia during the War. The resolution covered all branches of mining in the province, as it was felt that the rank and file of the profession, whether coal-miners or metalliferous miners, evinced the same eagerness to serve their country on the firing line. The meeting adjourned in the late afternoon and there was no evening session. The consensus of those who attended was that the meeting had been extremely successful.

The number of papers presented and offered did not by any means exhaust the capacity of the members and the time at the disposal of the meeting was all too short for full discussion. The society will have sufficient material in its transactions for 1917 to provide the widest scope for mature discussion at the next annual meeting, without the necessity of additional papers.

The meeting was thoroughly representative of the mining profession of Nova Scotia and was entirely made up of practical men busily engaged in the daily practice of their profession.

—*Canadian Mining Journal Report.*

CANADA'S MARCH EXPORT TRADE

CANADIAN exports of manufactured goods rose in the month of March to unprecedented figures, $69,239,486, exceeding the total for that division of our export trade in the full twelve months of 1914 by $87,562. The previous high mark for any month since war orders began to swell our export figures was $54,261,266.

With munitions output at the present time probably the largest yet achieved, and goods to a value of approximately $300,000,000 still to be shipped under old orders, March figures should be equalled or exceeded in the next few months. The one thing that may stand in the way of such a result would be the diversion of shipping to the carrying of food supplies rather than munitions, under more urgent needs for the former than the latter. That, however, is problematical.

The detailed March return offers on encouraging contrast to that of February, when the forward movement of goods from the Atlantic seaboard was temporarily checked by railroad congestion and the new German submarine menace. In February exports fell off to $68,224,383 and were less than $200,000 in excess of imports. In March they rose to $122,415,313, and although imports expanded rather sharply there was a trade balance in Canada's favor of $20,079,427.

Exports were approximately 34 millions higher than in March a year ago, but imports increased still more sharply, rising about 40 millions. The actual balance was, therefore, about six millions less tha nin March, 1916. This is disappointing in some respects, but the showing is still an amazingly good one, judged by before-the-war stadards. The comparisons continue little short of startling. In the good business year of 1913, after a big crop, Canada exported in March goods to the value of $34,874,000. Four years later the figures were approximately four times as large. There was a balance against Canada in March, 1913, amounting to upwards of 32 millions, which is this year replaced by a favorable balance of 20 millions.

Comparisons of exports and imports in March for six years, taking only domestic produce under the head of exports, and excluding foreign goods and gold from both export and import figures, are given in the following table:

March	Exports	Imports	Balance
1917	$122,415,000	$102,335,000	+ $20,079,000
1916	88,414,000	62,034,000	+ 26,380,000
1915	45,118,000	40,411,000	+ 4,707,000
1914	26,700,000	53,111,000	— 26,411,000
1913	34,874,000	67,603,000	— 32,729,000
1912	24,980,000	58,053,000	33,073,000

+ In favor of Canada.
— Against Canada.

The March exports in the usual classification shows gain over March, 1916, in every instance except the minor "miscellaneous" item. Comparisons follow:

	1917.	1916.
The mine	$ 9,980,711	$ 8,004,813
The fisheries	2,373,258	2,054,493
The forest	3,614,385	3,247,691
Animals, etc.	14,809,941	8,626,681
Agriculture	21,962,252	17,852,426
Manufactures	69,239,486	47,013,766
Miscellaneous	435,280	1,614,338
	$122,415,313	$88,414,238

The volume of the trade in March was considerably larger than in either January or February, although January yielded a net result more favorable to the country's external trade position. The continued rise in imports is disappointing in some respects, but it may be doubted whether it can be assigned to any larger part to extravagant buying, large importations of raw materials have been found necessary to carry out war orders when production of such materials within Canada had reached the limit of capacity. Increased imports of that description go forward into still larger figures in the export account later on.

Exports and imports for the first three months of the year compare as follows:

1917	Exports	Imports	Balance
Jan.	$ 99,106,259	$ 72,323,074	+ $26,783,185
Feb.	68,224,383	68,030,469	+ 193,914
March	122,415,313	102,335,886	+ 20,079,427
Total	$289,745,955	$242,689,429	+ $47,056,526

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

BORING AND RECESSING MACHINE FOR AIRCRAFT MANUFACTURE

In view of the fact that the manufacture of aircraft on a big scale is now being undertaken in Canada, the accompanying description of a boring and recessing machine for the wood propellers, designed by Thomas Robinson & Sons, Rochdale, England, should prove of more than passing interest. We are indebted to our British contemporary, The Engineer, for the data and illustrations. The machine evolved is intended for boring and recessing the bosses or hubs of airscrews or propellers, and, in addition, for half lapping and mitreing the laminations of four bladed propellers, as well as for recessing and drilling the spars and struts. Needless to say, the most accurate machining is required in these operations to ensure perfect balance and true running of the propeller.

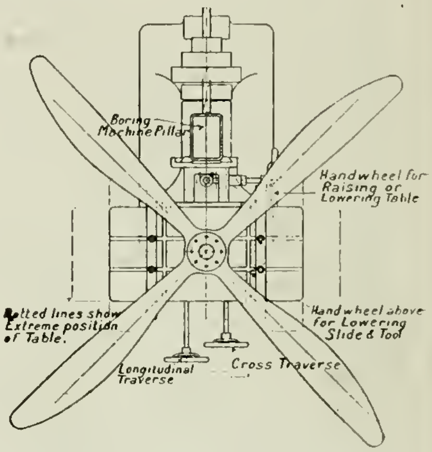
The ordinary type of boring machine, particularly where the spindle passes through its bearings, failed to satisfy the demands for the extreme exactitude and fine limits necessary in this class of work, though fairly satisfactory results were obtained as temporary measures by resort being had to devices for steadying the boring bits from below the work. These devices, however, impeded the operator, being difficult to set up and in the way when in position. Moreover, the old type machines were too restricted in their range of movement, ample provision in this respect being desirable not only for facilitating handling and ensuring the maximum output, but also for the purpose of preventing all avoidable disturbance of the propeller once the latter is set in position on the table of the machine.

The machine illustrated is claimed to leave a perfectly clean and true centre hole in the hub of the largest propeller, using a two wing twist bit as known to most machine woodworkers. The makers point out as a highly important feature of the machine, the method adopted for mounting the spindle. The whole head, complete with its bearings, rises and falls bodily, so that the maximum support is given to the spindle in all positions of the head. In the general type of wood borer, the spindle passing through its bearings must of necessity overhang, the overhang increasing with the depth of the hole to be bored, with, as a result, vibration and inferior work. The bit need only be steadied by its own shank in the spindle chuck, although a bit with a pin steady is sometimes preferred for finishing accurately to size. Other users prefer an adjustable recessing form of tool so that the diameter can be corrected for wear. By merely changing the boring bit or tool, a propeller hub can be completely bored, rounded on the edge of the hole, recessed when necessary, and the bolt holes drilled, without disturbing the setting of the work, i.e., the propeller, on the machine table. The compound movements of the table itself give all the required differences in position for the work. The machine is also made to suit the other method of working wherein given operations are confined to particular machines.

When recessing panels in the spars of aircraft, a former or profiling plate can be used to give the correct shape of the panel required; and, for half lapping and mitreing, a large diameter recessing cutter of suitable shape is all that is necessary, the timber being traversed past the cutter to form the recess or half lap. In the matter of speed also, the new machine is claimed to offer a solution of the one-speed objection more often than not found in borers of the old type. The latter generally ran about 1,000 revolutions per minute, while the new machine is arranged with three speeds, 1,200, 2,000 and 3,000 revolutions per minute.

The spindle head complete with its ball bearings which are of the "Skefko" double-row type, rises and falls on the main pillar. It is provided with the three speeds stated above, and is driven by belt over a pair of guide pulleys from a three-step cone on the counter-shaft at the back of the machine. The spindle head has a vertical movement by hand lever of 6 in., and by screw of 6 in., the maximum combined movement being 10 in. The driving pulley on the spindle is built up from steel tubing for lightness. It is 3½ in. diameter by 12 in. long, and carries a belt 2½ in. wide. The distance from the centre of the spindle to the machine pillar is 18½ in., and the spindle is arranged to swing cutters up to 7 in. diameter in the topmost position. Larger cutters, however, can be used if the spindle is lowered slightly. The chuck is bored for 1¼ in. diameter shanks.

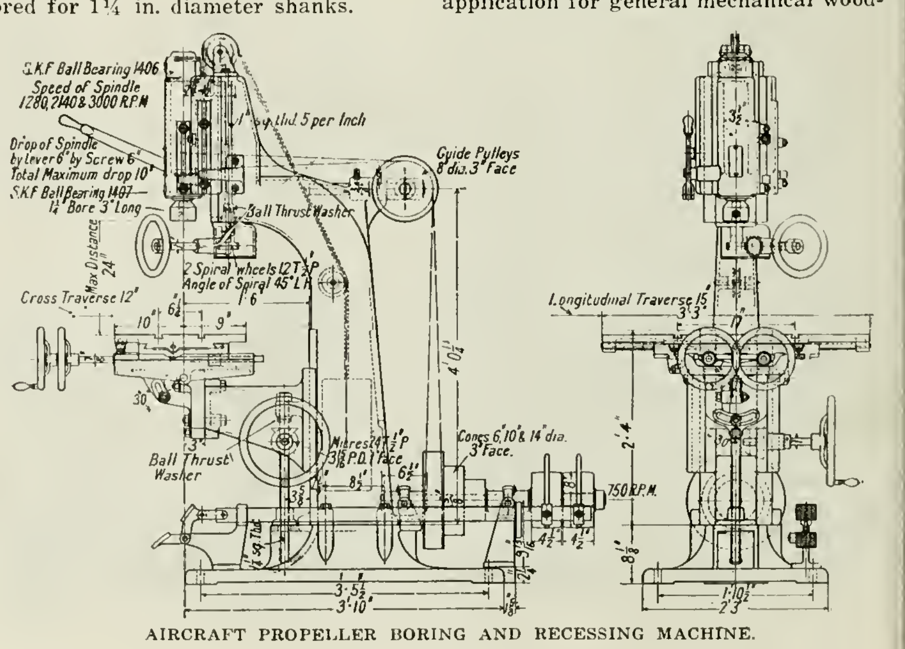
The size of the table is 39 in. by 19 in. It is slotted to carry a back fence and screw clamp and also eccentric lever clamps. It has a longitudinal traverse by screw of 15 in., a cross traverse by screw of 12 in., and a vertical adjustment by screw of 9 in. The maximum distance between the chuck and the table is 24 in. The table is also arranged to cant 30 degs. sideways, and to the front.



PLAN OF PROPELLER BORING AND RECESSING MACHINE.

All the motions of the spindle head and the table are provided with adjustable stops to pre-determine the movements required, and all the levers and handwheels are, as will be observed, brought to a convenient position for the operator. The fast and loose driving pulleys are 8 in. diameter by 4½ in. face, and run about 750 revolutions per minute.

Although the machine was primarily designed for aircraft work, it will be readily understood that it has very wide application for general mechanical wood-



AIRCRAFT PROPELLER BORING AND RECESSING MACHINE.

working, especially where either large, multiple, or fine limit work is required. Its installation, therefore, need not be considered, the makers urge, on the temporary basis as being only useful "for the duration of the war," since it will be a live and economic factor in any scheme for changing over from war to peace work.

METAL MELTING IN A SIMPLE CRUDE OIL FURNACE*

By H. S. Primrose

NOT every locality which has been selected for the large-scale melting and production of non-ferrous metals and alloys has been favoured with the possession of a high-pressure or cheap gas supply to facilitate operations. Many firms have therefore been content to purchase various forms of fixed or tilting furnaces of the oil-fired type and found them satsifactory. The chief difficulty with the majority of these, however, has been to retain or obtain the services of sufficiently skilled workers to operate the larger sizes so as to maintain uniformly good results both in the composition and strength of the castings and billets produced. The writer has been privileged to assist in the evolution of a very simple and efficient type of fixed oil furnace introduced by the Crittall Mfg. Co. for Government work. chiefly in connection with the rapid production of various grades of brass. The design is exceedingly simple, and permits of the use of unskilled labour throughout in its operation. The working drawings are reproduced to scale, and show the plan and several elevations of a single furnace, which is the left-hand unit of a pair of similar furnaces.

Construction

The furnace proper is constructed of the simplest engineering materials. The outer shell or casing is made of mild steel plates bolted together to form a rectangular box, the height of which may be varied to take large or small-sized crucibles. The one illustrated is capable of holding 100 up to 200 lb. pots, their elevation in the furnace being governed by the thickness of stool employed to raise them from the floor brick. The lining is of ordinary firebrick set in ganister to leave a circular opening, the corners between the lining and casing being packed with sand as an insulating material. The top of the furnace consists of two cast-iron plates resting on the top ring of firebrick and leaving a circular opening over which the furnace cover is placed during melting. The platform for the workmen is conveniently made of chequer plates, carried round all four sides of the furnace on channel or angle bars. This top also serves as a runway on which to move about the two-wheeled lifter for the furnace cover, which consists of a circular flat firebrick with a conveniently small aperture in the centre. The cover is bound round with a stout band of iron which serves to hold it together, and to enable it to be moved aside by the prongs of the lifting carriage.

It has been found that the best arrangement is to have the whole furnace above the floor-level, so that no pit or special foundation is necessary, and the construction and keeping clean of flues are completely done away with. In the event of a crucible cracking in the furnace whilst full of molten metal, there is no difficulty in removing the spilled metal through the frontal opening, which is usually, in working, kept closed by luting in a firebrick.

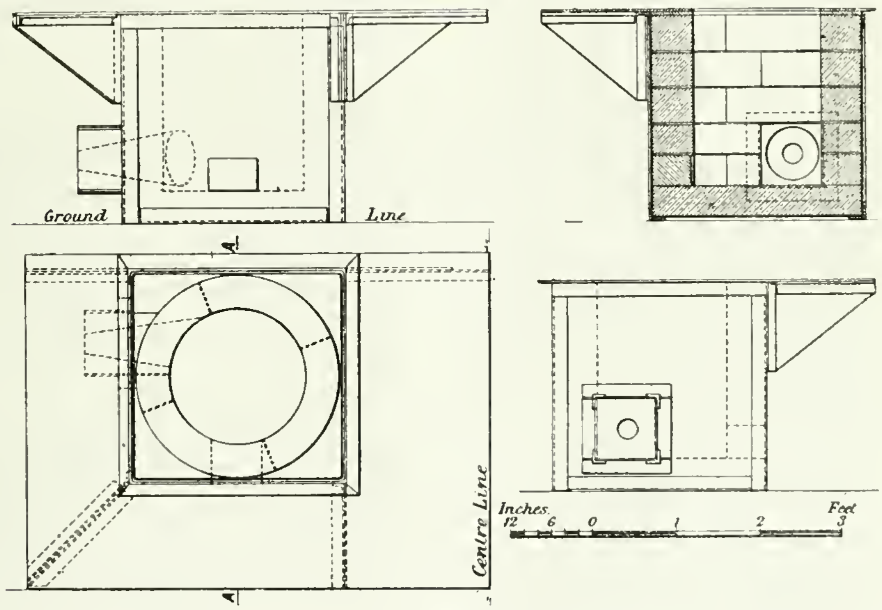
Air Supply

The space between each pair of furnaces can be utilised in conveying the necessary pipe-lines for the air and oil supply close up to the opening of the burner brick. Valves are, of course, required to regulate the inlet of each, so that the correct pulverising of the oil into a suitable spray is effected to give the right flame to envelop completely the crucible and have a small flame protruding from the cover opening.

The shape of the special burner brick allows the oil spray to spread out in a conical fashion, and, igniting on entering the furnace with a tangential motion, it causes the flame to sweep round in the annular space between the furnace walls and the crucible before passing out at the central opening in the firebrick cover. By using a single burner brick of the required shape, and also by having the firebrick slab for the floor of the furnace in one piece, there is no chance of leakage or escape of unconsumed oil, and as it is thus all burned inside the furnace, great economy in the heating power results, and uniform time of melting may be relied upon.

The form of oil-burner depends upon what type of air-pressure plant is installed in the works. Where compressed air is already in use it must be reduced in the foundry to not more than 25 lb. per square inch effective pressure at the burner valve. The burner must then be of the special high-pressure design, which is found to be exceedingly effective in producing the necessary pulverising action on the heaviest types of crude oil employment, and in this way high economy in melting may be secured. Such low figures as 1.5 gals. consumption for each hundred pounds of brass melted can be consistently maintained. The slightly increased cutting action of the high-pressure burner flame, both on the furnace lining, where carbonisation is likely to result, and on the crucibles themselves, makes this extreme saving of oil a questionable advantage in view of the short life of the crucibles and the more frequent patching required for the furnace lining.

Most satisfactory results have been obtained with the use of low-pressure burners, which can be used in cases where no high-pressure air system is in vogue. Small high-speed electric fans capable of producing about 12 oz. air pressure (i.e., from 20 to 22 in. of water gauge) can be readily employed to work four furnaces simultaneously. The only precaution to be taken in such a case is that the furnaces should be started up from cold not more than two at a time, and those which are not immediately in use at any period can have the air supply cut off separately. The consumption in this method of working is slightly more than two gallons per 100 lb. of metal melted, but against that must be offset the advantage of being able to melt with perfect regularity against time, as not more than 35 minutes are required to melt completely and pour 100 lb. of brass. 200-lb charges require only 50 to 55 minutes.



ELEVATIONS AND PLAN OF SIMPLE CRUDE OIL FURNACE.

Advantages

In addition to the advantage of being completely operated by unskilled labour, these furnaces have the obvious advantage of being easily removable, as they

*From a paper read before the Institute of Metals, March, 1917.

can be set down anywhere on a reasonably smooth floor. Besides being exceedingly easy to repair, they are constantly under the most complete control, simply by regulating the air and oil inlet valves. Their first cost is not great, and repairs are a very small item in their running. A large number have been in continuous operation night and day for over a year without any necessity for relining, and only slight attention to the walls in the way of patching with ganister has been needed. They are not nearly so destructive on crucibles as the various forms of gas flame employed in melting furnaces, and the ever-present trouble of clinkering, as with coke-firing, is completely done away with. The only resemblance to cleaning which must be attended to and that only on occasion when the correct air quantity has not been maintained during a run with very heavy or viscous fuel oil, is the deposition on the furnace wall opposite the burner of small accretions of solid carbon. It should never be allowed to interfere with the proper circulation of the heating flame, and the deposit must be barred off and removed when the crucible is withdrawn for pouring.

With 100-lb. pots there is no difficulty in withdrawing the crucible full of molten metal by hand, but when 200-lb. pots are used it is advisable to resort to a mechanical aid such as the quadrant lifting arm, with a chain to hook on to the basket lifting tongs. This very much lessens the chances of accident and minimises the effect of unsteady lifting out when manual labor alone is employed.

Melting Results

In a properly organized brass foundry all mixtures are controlled by analyses, and the charges accurately weighed out, after briquetting, if necessary. In this way it is quite feasible to do without any fresh copper. Complete returns are kept of the work and output of each shift, and these may be abstracted for each grade of metal made. The following table represents one month's output of "G" metal only:—

Metals melted:	lb.
Zinc	65.920
Cartridge cases	349.813
Swarf	709.218
Scrap	357,549
Total	1,482,500

Flux used, 7.312 lbs.

Aluminum deoxidiser. 820 lbs.

Foundry Production: Number of melts 14.825 of 100 lbs.

Billets produced. 124.855 =	1.312.225
Scrap and spilled metal	26.539
Metallic shot recovered from foundry dross	73.920
Total	1,412 684

Melting loss = 1.482.500 — 1.412,684 = 69,816 lbs. — 4.7 per cent.*

*The amount returned as loss is somewhat in excess of its actual value, as the weight of metallic shot recovered (33 tons) represents an average of only 60 per cent. of the total dross produced and treated by simple washing. Further treatment by concentrator revealed nearly 30 per cent. more metal to be got out.

Number of furnaces working, 18 to 22.
Total oil consumed, 32,599 gallons.

Oil consumed per 100 lbs. of metal melted, 2.2 gallons.

ROYAL COMMISSION REPORT ON RAILWAYS.

THE Royal Commission appointed last July by the Dominion Government to inquire into the general problem of transportation in Canada has submitted its report. The report was presented to Parliament on May 3. The Commission consisted of Sir Henry Drayton, Chairman of the Dominion Railway Commission, W. M. Acworth, a British expert on railway rates and economics, and A. H. Smith, president of the New York Central lines. The majority report was accompanied by a minority report by A. H. Smith, who differs from the other commissioners principally on the question of nationalization.

Majority Report.

The majority report prepared by Sir Henry Drayton and Mr. Acworth, involves the creation of practically two great systems in Canada, one publicly owned and the other a private enterprise, the Canadian Pacific, both under control as to rates, of the Dominion Railway Board, both operated by expert railway men, both serving their own economic territories, competing with each other, but each serving the people who contributed nearly all the financial assistance which built them.

The report declares that if the chief bane of Government operation of railways, namely, political interference, is eliminated, the proposed new great national systems, operated on a strictly commercial basis, can be put, within a comparatively short period of years, upon a satisfactory financial basis.

Minority Report.

The American railroad expert is opposed to Government ownership and operation, believing that the best results can be achieved by continuing private enterprise, with the reorganization and better co-ordination of the work of the Grand Trunk Pacific, Grand Trunk, National Transcontinental and Canadian Northern. He recommends, in brief, the taking over the Grand Trunk Pacific with its branch lines in the West by the Canadian Northern, leaving the latter company free to operate in the Western part of Canada, while the Grand Trunk should lease the Eastern lines of the Canadian Northern from North Bay east, and confine its operations to Eastern Canada. With regard to the Intercolonial and National Transcontinental, he believes that they should be left as at present as a continuous system from seaboard to the grain-distributing centres. The Commissioners agree that the Canadian Pacific is now giving good service, and should not be interfered with. The Commissioners also agree that present conditions are economically bad, that there is wasteful duplication of lines, lack of co-ordinated transportation economy, and heavy deficits to be met on behalf of the railways by the people of Canada for years to come, unless some scheme of radical reorganization is promptly carried out.

FISHERMEN V.C. AND THE KING

TOM WING, M.P., tells how he accompanied a fisherman from a mine-sweeping trawler, who was awarded the V.C., to Buckingham Palace to receive his decoration from the King.

"He rolled along with me in true seafaring style," says Mr. Wing, "until, as we approached the gates, I remarked. 'We must pull ourselves together, otherwise we shall not be admitted.' My gallant friend who had been chewing a plug of tobacco, took it out of his mouth and carefully put it in his cap.

"It is usual for the King to shake hands with recipients, and when he did it on this occasion my man would not let go. He held on, and to make certain it was all right, he put his other hand on it. Then he looked at his Majesty as much as to say: "Are you the King, or are you only "kidding" me?"

"When we got outside he said it was all like a dream, and he felt for his pipe to make quite sure he was awake."

CANADIAN TONNAGE REDUCED

A SLIGHT reduction in the tonnage of ships on the Canadian register during the first wo months of the year is shown by statistics compiled in the Marine Department at Ottawa. At the end of February the total tonnage was 475,693 representing sailing vessels, and 794,314 representing steamships, as compared with 476,983 tons in sailing ships, and 799,183 tons steamers at the close of December last.

In January vessels having an aggregate tonnage of 11,743 were transferred from the British register to Canada, and 900 tons were accounted for by new construction. February the figures were, new construction 1,164 tons; transfers from British to Canadian register 1,464 tons; transfers from foreign to Canadian register 758 tons.

There were stricken off the Canadian register in January 14 sailing vessels, aggregating 1,271 tons, which were broken off, five small steamers similarly disposed of and vessels of 4,440 tons in all sold in the United States. In February 5,286 tons were lost through wrecks and 2,212 tons were accounted for by vessels condemned.

Didn't Recognize Danger.

The black sheep of the family had run away to sea. The first night he was on the lookout and suddenly spied three lights—red, green, and white—the port, starboard and masthead of an approaching vessel. Every seaman knows that when these three lights are to be seen at the same time it means danger, but the black sheep wasn't a seaman.

"Ahoy, there!" yelled the officer on deck. "What's that ahead of us?"

"Don't know," answered the black sheep, calmly. "I think it's a chemist's shop!"

DEVELOPING OUR SHIPBUILDING ALONG RIGHT LINES

JUST what Canada's contribution will be towards curbing Germany's submarine menace is somewhat problematical. The situation as we see it is a complex one, although if judgment were to be based on the lavish expenditure of printers' ink setting forth the ease and rapidity with which seaworthy ocean carriers can be fabricated and commissioned, there is little to it. The steady depletion of the world's shipping by enemy submarines has reached a crucial stage and rehabilitation is of the greatest possible urgency. We have apparently lost sight of the fact, however, that extermination of the menace is rather more worthy of attention than the multiplication of targets for its special benefit. What availeth, even were Great Britain, the United States and Canada, able to float a ship per ship sunk, if "plunger" warfare be not speedily arrested and ultimately wholly eliminated. A "feed the brute" policy is essentially wrong and has not the faintest hope of success of any kind, unless it be the imaginary one of using up German raw materials—the constituent of torpedoes and a few ill or well-directed shell, or be the most temporary of stop gap expedients.

The effort to develop a Dominion-wide shipbuilding industry is a laudable one, even although there is little novelty about it beyond the meantime hysterical setting born of lack of knowledge of what is involved and originating in sources as far removed from worth-while achievement as the Poles are apart, and with about the same prospect as the latter of coming together. There is an evident disposition to infer that because "sermons are to be found in stones and books in running brooks," shipyards are to be found on trees, in departmental stores or other equally foolish locations, ready-made. The movement to create a "broad gauge" shipbuilding industry in Canada has been operative for quite a number of years, and the outbreak of hostilities has but served to steel the energies of the men behind the movement to still greater effort. It has never been recognized, however, as the Nation's Business, and if one may express an opinion on the situation as we find it to-day, recognition is still lacking.

In April, 1913, fifteen months preceding the declaration of war, a Memorial was presented to the Canadian Government which in very full detail set forth the numerous disabilities under which our shipbuilders labored, and demonstrated beyond question the benefits which would accrue to our citizens as a whole if a real, earnest attempt were made to foster the industry officially. To-day we are inclined to think this Memorial is a haunting nightmare to the responsible Government at Ottawa. That action solicited and refused four years ago cannot now be longer delayed is generally admitted, while evidence of a veering round to it is already apparent in our Finance Minister's offer of $10,000,000 to the Imperial Munitions Board with a view to stimulating at least wood shipbuilding.

We are not of those who deem the Imperial Munitions Board incapable of directing Canada's as well as Britain's shipbuilding programme, and from the manner in which shell production has been developed and expanded under its administration, few will be inclined to differ with us. Under any circumstances, even those prevailing on the high seas to-day, let us keep common-sense and reason from running riot to the extent that we can build up a sound, permanent, worth-while shipbuilding industry overnight, so to speak, for it can't be done. The men who have been bearing the burden and heat of the day in past years by keeping the industry alive, and who more than any others are the real judges of the whole situation, had this to say on the subject in their Memorial of four years ago:

"Apart from managers, superintendents, clerks, etc., the staff of foremen for the shipfitters, pipefitters, plumbers, coppersmiths, boilermakers, sheet iron workers, riveters, moulders, patternmakers, machinists, blacksmiths, carpenters, joiners, painters, mold loftsmen, riggers, pneumatic tool men, helpers, etc., is very large; and these men must be permanently employed, carefully selected, and gradually picked up. **It takes about seven years to build up a good organization.** The last named consideration makes it apparent that any scheme of aid, once embarked upon, should be guaranteed for a fixed period, and long enough to enable yards to get their organization established and then show results. An aid period of ten or fifteen years is indicated."

A parallel has been sought to be drawn between shellmaking and shipbuilding, to the extent that our almost immediate success in tackling the former means a correspondingly prompt achievement in the latter. To those who so reason, a few minutes heart to heart talk with any of our shipyard managements on the labor phase of vessel construction as compared with that of shellmaking, would be worth a whole lot, so much so that it would possibly be discovered that they know quite as much about the in'ards of the one industry as about the other, and quite little of either.

We are not of those who despair of Canada taking a prominent place in the world's shipbuilding and shipowning, rather are we keenly optimistic about it, and while in the past little heed was paid the possible importance of either, or their opportunities, the world-wide dearth of ocean transport has now come equally close home to us as it has to other warring or neutral nations, and demands that notice be taken and action be initiated. The inherent possibilities of shipbuilding and marine engineering are realized as never before in our experience, combining as they do staple industries in themselves, of large proportions, and the medium through which a myriad other enterprises, large and small, agricultural, mineral and manufacturing, may find opportunity to expand and develop.

The General Market Condition and Tendency

THAT prices of iron and steel will continue to advance seems now assured. Developments in the steel market in the United States point conclusively to higher prices and a more pronounced shortage of steel. These conditions will be reflected in Canada, affecting consumers in regard to both imported and domestic steel products. Manufacturers using merchant bars and small shapes, etc., are experiencing considerable difficulty in obtaining material for their factories and operations are being in many cases seriously restricted. In regard to imported materials, the situation seems likely to become more acute. The more important price changes to note this week include wrought pipe, steel spikes, iron rivets, fire-weld chain, billets and galvanized sheets, which have all advanced, while higher prices may be looked for on steel plate, boiler rivets, black sheets, bolts and nuts. The pig-iron situation is unchanged and domestic iron is still off the market, although there is some hope of improved conditions developing in the near future. Machinery cast iron and malleable scrap are higher and in good demand. Steel scrap is also in good demand at unchanged prices, but copper, brass and zinc scraps are dull and easy. The non-ferrous metal markets are firmer and the situation has generally improved. Tin and lead have advanced, but antimony is weaker and has declined. Copper quotations continue nominal and the market is quiet, although somewhat firmer than it has been during the past few weeks. Machine shop supplies continue in good demand at firm prices. The machine tool market is fairly active, business being of a more general character than formerly.

Montreal, Que., May 7, 1917.—The week has been comparatively quiet in industrial circles, no features having developed to change the general situation. Further announcements regarding the war policy of the United States are awaited with considerable interest, as it is expected that some changes will result when the final arrangements are made. It is understood that the co-operation between the United States and the Allied nations will be of the closest description, and industrial operations will naturally be governed accordingly. Navigation on the Great Lakes and Rivers has again become an active factor in the matter of transportation, and in many respects the railroads will be relieved from much of the heavy business, so pronounced during the past winter months.

Pig Iron

With the exception of a few advances on certain grades of American pig iron, the market is unchanged. The volume of business being placed for the coming year is gradually increasing and orders are now on the books for delivery in the second quarter of 1918. Advances this week are confined to the Pittsburgh district, the increase being nominally $1 per ton. The advance on composite pig iron during the week has been 40 cents per ton. Canadian pig is practically off the market, but for what little is available dealers here are quoting the nominal price of $50 per ton.

Steel

The attention of the steel industry is still centered in what the American government will do in connection with the purchase of steel and other requirements. With the close co-operation of the several Allied governments with that of the United States, in the formation of a policy in carrying on the war, it is anticipated that no radical changes will be made that might disturb the condition of present industrial activities. This to some extent will allay the anxiety that has been so prevalent during the past weeks, and producers are looking forward to the placing of government orders at prices much closer to those at present quoted, than those previously expected. An indication of future possibilities may be had from the report that additional requirements for copper will be filled at much higher figures than those paid for the first lot ordered. While the United States naval requirements call for the purchase of steel plates at $2.90 and bars and shapes at $2.50, it is not expected that corresponding prices will be paid for other classes of steel, owing to the higher cost of production prevailing at the present time. With the entrance of the United States into the war, the situation has become much more complicated; some American producers are of the opinion that the Allies should be supplied at prices fixed by the U.S. Government for their own requirements, while others contend that current conditions should be maintained. The general market has been somewhat quieter this week and price advances have been few. Better conditions prevail in the delivery of billets and sheet bars to those consumers who get their supplies on regular contract; a quieter situation has developed in structural steel, consumers who can afford to wait are holding up construction, but in many cases the high prices that prevail are apparently little drawback to the buying of material. Recent developments promise the plate situation very little prospect of any relief for a long time to come.

Rail mills are fairly active, the demand both for home and export having shown a good increase during the week. Wire mills are having considerable difficulty in supplying the demands of the trade and an effect is being made to cut down orders so that a fair distribution can be made to the various consumers. While the prevailing price has not been changed, it is reported that sales are being made at higher figures than the market quotes. An advance that is soon expected to become general, has been made on wrought iron pipe, this advance being approximately $12 per ton. The demand for this product has been so heavy that many mills are filled up for the remainder of the year and in some cases 1918 delivery has been accepted. The local situation is practically unchanged; dealers here report the demand has more of a normal tone, with the trade evidently awaiting the developments in the States before making additional demands upon the market. Delivery of material is much better but the difficulty appears to be in getting shipment from the mills.

Metals

The report that higher prices will be paid for additional copper requirements for the American government has had a cheering effect upon the general situation, but until a definite announcement has been made the trade will be kept more or less in an unsettled condition. Copper is somewhat stronger on the New York market. Tin is very strong and higher. Spelter is in better demand and stronger. Lead is higher and more active. Antimony is more plentiful and easier. Aluminum is firm and steady.

Copper.—It is reported that further purchases made by the American government for their future requirements, will be made on a basis of around 25 or 26 cents per pound; this possibility has had the effect of adding strength to the market. Negotiations now under way may result in the U.S. Government arranging for the purchase of all the copper required by the allied nations. This condition would have the tendency to eliminate competition and establish a fair price for supplies needed for war purposes. The consumption of copper at the present time is as heavy as ever in the past and even with the greater production during the past year, the supply is still below the demand. In addition to this, very little is known as to the actual losses through the activity of submarines. While general conditions show little change, the New York situation has a better tone, and higher quotations prevail; lake is ½c higher at 31½c; electrolytic has advanced one cent and is quoted at 32c, while castings at 29½ shows an advance of 2¼c per lb. The local situation is unchanged with dealers quoting last week's prices of 38c for lake and electrolytic, and 37c for castings.

Tin.—Owing to consumers being well supplied for immediate needs and a lack of demand for future positions, the week's market has been very quiet. The apparent shortage of the visible supply has retained the market in an exceptionally firm position, and but for the poor demand the situation at present would be much stronger. Advances on the London market have also had a good effect here and a firmer tone is evident. New York quotation remains firm at 58¾c per lb. On a good demand local dealers are asking 60½c, this being an advance of 2½c per lb.

Spelter.—Following the report that Government buying would probably be made at a much better price than previously anticipated, the New York situation has become stronger, and sales during the week have been greatly improved, together with heavy inquiry for future metal. However, the market is still undecided as to the actual intentions of the government and the situation is characterized by the uncertainty that has prevailed during the past few weeks. London is firm while New York quotations show an advance of ⅛c per lb., the current price being 9½c per lb. Local spelter is ½c stronger, the current quotation being 13½c per lb.

Lead.—Producers are still reluctant to make sales at prevailing prices until a declaration is made by the Government as to the price they expect to pay for their requirements. Dealers who have been striving to secure metal are now awaiting developments. Owing to the heavy demands for this metal the market retains a very firm position, with the undertone still stronger. The trust price during the week has advanced ½c the quotation being now 9½c; independents are asking 10¼c, this being ¼c higher than last week. The situation here has taken on strength and dealers are asking 13c per lb., an advance on the week of ½c.

Antimony.—Recent heavy shipments of metal have increased the supply and the market has become easier. The situation is still influenced by the uncertainty of pending developments. Light demand and good supply has created a weakness on the New York market, a decline of 6½c placing the quotation at 27c per lb. Local antimony is still quoted at 27c per lb.

Machine Tools and Supplies

The machine tool situation is again being affected by prevailing conditions, more especially in the United States, where the industry is practically at the disposal of the government. While the machine tool plants are not under the direct supervision of the authorities, the placing of machinery is more or less in their hands, as certain equipment that has been under construction for neutral countries, has been diverted to war needs in the States, at the direction of the government. Production of government equipment is being executed with all possible speed. Both in Canada and the United States, the demand for wood working machinery has shown remarkable increase, owing to the great activity that has taken place in the shipbuilding industry. A fair business is still being done in single machines for munition makers, but the heavy activity in this respect has undoubtedly been passed, at least for the present. The probability that additional orders will shortly be placed for the lighter weight shells, may cause a resumption of machine tool activity in the early summer months. With the increased pressure recently placed upon the machine manufacturers in the States, together with the constant advance in the price of all raw materials, the higher cost of equipment will likely be an early future feature.

Scrap

The situation in the old metal market is still firm, but with an unsettled undertone, due to the uncertainty that characterises the conditions in general. Dealers report a fair business but are anxiously awaiting further developments, as they are reluctant to stock up under existing conditions. Steel and iron scraps are holding firm while old metals are somewhat firmer. New York is quoting an advance of ½ cent on brass scraps and one cent on old zinc scrap, with slight increases on other metals. Prices here are unchanged.

Toronto, Ont., May 8.—Events in the United States are gradually assuming a definiteness of character, which is tending towards more settled conditions in Canada. Developments in the international situation indicate a continuation of the prosperity now prevailing in this country for some considerable time. Munitions work is showing signs of declining, although orders for shells will continue to be placed during the year.

Developments in the shipbuilding industry are being followed with interest, and this work will help to make up for the decline in the munitions industry.

Steel

Steel prices are still advancing, and there is no indication of any recession in the market. The demand for steel of all descriptions continues heavy, and is taxing the capacity of the mills to supply the tonnage required. The requirements, however, are such that the mills cannot take care of all the business offering, and consequently are behind on deliveries. The result is that there is a shortage of steel for many purposes other than munitions. The present high cost of steel, particularly structural material, is restricting building operation, while the high cost and scarcity of merchant bars and small shapes, etc., is handicapping manufacturers who use these materials. The scarcity of iron and steel is likely to become more acute as the demand is increasing, and consumers will be worse off than ever. Conditions in the steel trade in the United States are affecting the situation in Canada to a like degree. The American Government requirements of steel will undoubtedly be heavy, which in view of the sold-up condition of the mills will tend to force prices up. Steel prices in Canada will advance in sympathy, which means higher prices for the consumer on both imported and domestic material.

The more important price changes to note this week are wrought pipe, pressed steel spikes, proof coil chain, iron rivets and billets. Wrought pipe has advanced $14 per ton, and includes both black and galvanized material. Pressed spikes have advanced 60c per 100 pounds, due to the high cost of raw material. For the same reason, chain has advanced approximately 5 per cent. The new discount on iron rivets, 7/16 in. and smaller is 17½ per cent. No change is noted in the situation in iron and steel tubes, and prevailing prices are largely nominal. The new demand for steel plates is heavy, and prices are very firm. In view of the heavy demand for plates, both present and future, higher prices are looked for.

Galvanized sheets have advanced 50c per 100 lbs., and are now quoted as follows:—Premier No. 28. U. S., $8.70;. and 10¾ ozs., $9 per 100 lbs. Black sheets, No. 28 gauge, are a shade higher at $7.85 per 100 lbs. The heavy demand for sheets in the States, combined with the high cost and scarcity of raw materials, is forcing prices up and further advances may be expected.

All indications in the market in the United States point to higher prices and more pronounced shortage of steel. Government buying is decidedly heavier, and will likely place large orders for steel within a short time. It is becoming more evident that the American Government and the Allies will combine in placing orders for steel, which may result in the present fixed prices being revised upwards so as not to disturb the situation. Steel bars have advanced to 4c, and tank plates 6.50c Pittsburgh. Bessemer billets, O.H. billets, and O.H. sheet bars are now $80, and forging billets $105 f.o.b. Pittsburgh. Ferro-manganese prices now range from $400 to $500 per ton.

Pig Iron

The pig iron situation locally is unchanged, and no prices are obtainable. In Buffalo, prices range around $45 furnace for all grades. The furnaces are not anxious to do business, as very little iron is available that has not been contracted for. Prices have advanced on several grades of pig iron, including the following:—Grey forge, Pittsburgh, $39.95; Lake Superior charcoal, $46.75; and Bessemer, Pittsburgh, $43.95.

Scrap

Prices of steel and iron scrap continue firm, with an upward tendency, but copper and brass are easy. Machinery cast iron has advanced to $22, and malleable scrap to $16 per ton. Heavy melting and other steel scraps are firm, but unchanged. Light copper is down 1c and scrap zinc is ½c lower.

Machine Tools

The general situation in the machine tool market is unchanged. Business continues fairly active on miscellaneous lines of a general character. Except on lathes, deliveries are not likely to improve on imported tools, as the market in the States is becoming more active, due to increased demand for munitions equipment. Prices on machine tools are very firm, and will probably advance owing to the steady increase in cost of raw material.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Supplies

Business continues good and prices are very firm, showing, however, less tendency to advance. There have, however, been a few changes during the week. Locomotive screw jacks now carry a discount of 20 per cent. as against 35 per cent. formerly. Hand and platform trucks are now 10 per cent. off list. Asbestos wick packings are $1.30 per lb., and asbestos millboard 25c per lb. Pure Manila rope has advanced 2c, and is now 33½c base, ⅝ in. and larger.

Metals

Although the situation has improved, the uncertainty as to the American Government requirements continues to be dominating factor in the metal markets. The fear that the Government purchases at low prices will depress the market is disappearing and giving way to a more optimistic feeling. Prices this week are firmer. Tin and lead have advanced, but antimony is lower. Copper is showing moret strength, but is unchanged, and prices continue nominal. Solders have advanced. Business locally continues brisk and the outlook is favorable.

Copper.—Prices are unchanged and nominal and the market is firmer. It is understood that the purchases of copper for the Allies are likely to be made through the American Government, which will tend to eliminate competition, and should result in fair market prices being established. The present Government price is 25c. There is no spot copper, and very little re-sale metal to be had. So little July copper is available that there is some difficulty in arriving at a definite price. Lake and electrolytic copper is quoted at 37c and castings at 36c per pound.

Tin.—There is a scarcity of spot tin and holders are not anxious to sell in view of the short supply and uncertainty of replenishment. The increase in insurance rates is also tending to stiffen prices of tin, while there is some uncertainty as to the amount of metal which will be allowed to come forward by the British Government. Tin has advanced 1c locally, and is now quoted at 59c per pound.

Spelter.—The demand continues light, and the market is dull, with prices unchanged. Buying by the American Government, which is expected shortly, is expected to strengthen the market. Local quotation, 12c per pound.

Lead.—The position of this metal continues strong, and it would only take a fairly insistent demand to send prices up. Lead has advanced ¼c, and is now quoted at 12½c per pound.

Antimony.—The market is weak and prices have declined. There is but little demand for spot antimony, but some interest is being shown in futures, principally May and June shipments from the East. Antimony has declined 6c locally, and is now quoted at 30c per pound.

Aluminum.—The market has grown a trifle easier, but quotations in the meantime are unchanged at 68c per pound.

Solders.—The high cost of tin and lead has resulted in an advance of 1c on solders. Guaranteed is now quoted at 36c and strictly at 34c per pound.

TRADE ENQUIRIES.

THE Department of Trade and Commerce, Ottawa, has received the following enquiries:

656. Sheet iron.—A manufacturers' agent in Newfoundland requires 10 bundles galvanized sheet iron 2 feet 6 inches by 6 feet, 18-gauge, 20 bundles black sheets 2 feet by 6 feet by 24-gauge, 15 bundles black sheets 2 feet by 6 feet by 26-gauge.

657. Bar iron.—A Newfoundland firm asks for quotations on 20 tons bar iron. 1 inch by ¾ inch; 200 tons, 1 inch by ¼ inch; 60 tons, 3 inches by 1 inch; 120 tons, 4 inches by 1 inch; 20 tons, 4 inches by 1¼ inch; 10 tons, 6 inches by 1 inch; 20 tons, 2½ inches by ¾ inch; 40 tons, 2¼ inches by ½ inch; 2 tons, ½ inch square iron; 4 tons, 1¼ inch round iron

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul. Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46. Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbegd No. 4, Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Care British Consulate General, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

(good quality); 4 tons, 1 inch round mild steel. Shippers to effect ordinary marine and war risk insurance.

667. Steel.—A Port Elizabeth firm requests particulars from Canadian manufacturers prepared to export octagon, spring steel and iron.

INCORPORATIONS

J. P. Quinlan Mfg. Co., has been incorporated at Toronto with a capital of $40,000 to carry on a general sawmill and planing mill business at North Bay, Ont. The provisional directors are Joseph P. Quinlan, Maurice McQuinty and J. Landreau.

Steel Lockers Ltd., has been incorporated at Ottawa with a capital of $40,000 to manufacture steel and metal lockers and furniture at London, Ont. The incorporators are William P. Brown, Herbert J. Sutherland and Charles E. Jarmain all of London, Ont.

Turnbull Electro Metals Ltd., has been incorporated at Ottawa with a capital of $50,000 to carry on business as iron and brass founders, engineers, boilermakers, machinists etc., at St. Catherines, Ont. The incorporators are Robert Turnbull of Welland, Ont., James Brockett Tudhope and William H. Tudhope of Orillia, Ont.

The Hydraulic Machinery Co., has been incorporated at Ottawa with a capital of $200,000 to manufacture and repair all kinds of hydraulic presses and pumps, and screw presses etc. Office at Montreal and the incorporators are Gerald A. Coughlin, Francis G. Bush and George R. Drennan all of Montreal.

The Nominique Pulp & Lumber Co., has been incorporated at Ottawa with a capital of $300,000 to acquire and operate lumber and planing mills. Head office is at Montreal and the incorporators are Eugene Patenaude, Herbert G. Boyle and Louis Sessenwein all of Montreal.

Valleyfield Tool Mfg. Co., has been incorporated at Ottawa with a capital of $100,000 to manufacture all kinds of machinery, tools, implements, foundry supplies etc., at Valleyfield, Que. The incorporators are James M. Garant, Charles G. Ogden and John L. Reay all of Montreal.

Colonial Supplies Ltd., has been incorporated at Ottawa with a capital of $50,000 to manufacture lubricating and medicinal oils, soaps and greases etc. Head office is at Montreal and the incorporators are Spencer L. D. Harris, Charles Champoux and Charles H. Skelton all of Montreal .

Canadian Utilities, Steel & Engineering, Ltd., has been incorporated at Ottawa with a capital of $49,000 to manufacture and deal in all kinds of gauges, tools engines and machinery with office at Montreal. The incorporators are John McNaughton, William B. Scott and James G. Cartwright all of Montreal.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Montreal, Que.—Farand & Delorine will build an addition to their structural steel plant.

Chatham, Ont.—The Dowsley Spring & Axle Co., will extend their plant at a cost of about $5,000.

Hamilton, Ont.—The Canadian Shovel Co., will build an extension to their plant. McPhie & Kelly of Hamilton, are the architects.

Montreal, Que.—The Dominion Bridge Co., Lachine, have equipped a part of their plant for building marine engines.

St. Mary's Ont.—The St. Thomas Quarry Co., who recently had a fire at their plant will rebuild the damaged section.

Tillsonburg, Ont. — The Tillsonburg Foundry & Machine Co. propose to erect a machine shop and install new equipment. The cost is estimated at $10,000.

Esquimalt, B.C.—A workshop will be built here by the Department of Naval Service, Ottawa, from which full particulars of the proposed plant may be obtained.

Walkerville, Ont.—Construction work on the Chalmers Motor Co. plant, which was destroyed by fire recently, is well under way, and rebuilding will be proceeded with as fast as possible.

St. John, N.B.—Tenders will be called shortly for the erection of a power house and laundry at the General Hospital. The estimated cost is $46,000. Full particulars may be obtained from F. Neil Brodie, architect, St. John, N.B.

Collingwood, Ont.—William Kennedy & Sons, steel plant, is now in full operation, an important contract for their product having recently been secured. A contract has been signed by the company with the Hydro-Electric Commission for an additional 1000 h.p. for the new electric furnaces.

Stratford, Ont.—A substantial addition to the present plant of the McLeod Milling Co. has been decided upon, and building operations are expected to commence at an early date. The existing steam plant will be taken out and electric motors installed throughout the mill. A new office building will also be erected.

Port Arthur, Ont.—J. J. Carrick, M.P., and his associates will shortly commence the erection of a pulp and paper mill, the initial unit of which will turn out 360 tons of pulp a day. A site covering 57 acres has been purchased just outside the city limits beyond Bare Point. Pulpwood will be obtained from the Black Sturgeon and Pic river limits. The initial unit will use about 18,000 h.p. which will be obtained from the Hydro-Electric Commission who will develop the power from the Nipigon river.

Windsor, Ont.—The Windsor Tool & Machine Co. are building a one storey, 84 ft. x 52 ft, addition to their plant which will comprise a machine shop and office accommodation. The roof will have saw-tooth skylights over the centre of shop but will be constructed to carry machinery when another storey is added later. The windows will have steel sash and a fire protection system will be installed. A steam heating system and electric arc lamps will also be installed. The cost as estimated at $10,000. J. C. Pennington of Windsor, is the architect.

MUNICIPAL

Guelph, Ont.—The City Council contemplate the purchase of a motor truck for the fire department.

Tillsonburg, Ont.—A by-law will be voted on by the ratepayers on May 14 to provide for exemption from taxation of the Canadian Cereal & Flour Mills Co.

Stratford, Ont.—The Public Utilities Commission has decided to purchase a number of fire hydrants for better fire protection.

Hamilton, Ont.—The Board of Control has decided to buy a motor flusher from the Menard Motor Flusher Co., of Windsor, Ont. The price will be $5,550.

Sherbrooke, Que.—A by-law will be voted on shortly authorizing the borrowing of $80,000 required for constructing a transmission line to the power development at Weedon.

Brantford, Ont.—Tenders will be called shortly for two pumps of 300 imperial gallons per minute each and 25 h.p. motors. Engineers, Chipman and Power, Toronto.

Oakville, Ont.—The Town Council has passed a by-law providing for an expenditure of $20,000 for extensions and improvements to the water and light systems.

Tillsonburg, Ont. — The ratepayers will vote on a by-law on May 14 to grant $10,000 by way of loan to the Tilsonburg Foundry & Machine Co., Limited.

Davidson, Sask.—A by-law will be submitted to the ratepayers on May 21 to raise $8,000 for the construction of a new school and $4,500 for power house improvements.

Toronto, Ont.—By a unanimous vote the Board of Control has decided to abandon any further work on the extension of Terauley street. This decision is in accord with a recommendation from the civic officials.

Hamilton, Ont.—The Board of Control has decided to apply to the Provincial Board of Health for an order to have emergency steam pumps installed at the beach water works plant. The pumps will cost $107,000.

Mitchell, Ont.—A by-law will be voted on by the ratepayers on May 21 to raise $10,000 for the purpose of macadamizing certain streets and $400 for the purchase of a site for a knitting factory for A. Burritt & Co.

Hamilton, Ont.—The Board of Control has decided to install a refrigerating plant, the cost not to exceed $6240, in the new mountain hospital. This was the amount of a tender made by the Canada Ice Machine Co. of Toronto.

Toronto, Ont.—Approval has been given by the Board of Control to the plans of Parks Commissioner Chambers for proceeding with the city's share of the Humber boulevard work. The cost of this work will be $15,000.

Rosthern, Sask.—A by-law will be prepared to raise $25,000 for the purpose of purchasing an electric light plant. Underwood & Murphy, engineers, of Saskatoon, have advised that a 100 h.p. plant be installed but the council favors a 75 h.p. unit.

Alliston, Ont.—It is proposed to raise $32,000 to provide for the taking over of the Alliston electric light plant and repairing and improving same for the purpose of distributing electric power to be supplied by the Hydro-Electric Power Commission of Ontario.

Longueuil, Que.—Permission has been given a few weeks ago to the Stowell Screw Co. to erect a factory on the corner of Montarville and St. Lawrence streets, but the council has recently received a letter from Dr. N. Jacques protesting against the factory being built. The matter will be discussed at the next Council meeting.

Aurora, Ont.—At a meeting of citizens held in the Town Hall here on May 2, E. C. James, civil engineer for the county, explained a suggested sewage system for the town, illustrating the plan with diagrams. The estimated cost of the improvement is $80,000, and it was the opinion of the meeting that the matter should not be considered until after the war.

GENERAL

Hamilton, Ont.—The National Paper Goods Co. are building an addition to their factory.

Toronto, Ont.—De Laplante's planning mill at East Toronto is again in operation, the firm having secured an order for manufacturing a patent box.

Toronto, Ont.—A building permit has been issued to the Dominion Glass Co., for the construction of an addition to their factory to cost $5,000.

Hamilton, Ont.—There was a fire on April 30 at the premises of the Laidlaw Bale Tie Co., when the cooper shop was totally destroyed. The loss will be about $5,000.

Stratford, Ont.—At a meeting of directors of the National Portland Cement Co., it was decided to reopen the plant at Durham at once for the manufacture of cement, this time as a rock proposition. The works have been closed since June last. R. H. McWilliams of St. Marys, was again appointed manager.

North Bay, Ont.—The industrial bylaw empowering the corporation to guarantee bonds of the J. P. Quinlan Manufacturing Co. to the extent of $15,000 was carried by a large majority of the ratepayers last Monday. The company will manufacture furniture and church and school fixtures.

Nicolet Falls, Que.—On April 29 the pulp mill and sash and door factory here, of the Lotbiniere Lumber Co., were completely destroyed by fire. The building and machinery are a total loss. The The property belongs to F. N. McCrea, M.P., and E. W. Tobin. The damage is placed at $80,000, with but $40,000 insurance.

PERSONAL

F. Tissington has resigned from the position of chief engineer of MacKinnon Holmes & Co., Sherbrooke, Que.

Capt. B. T. Eastaway, who had commanded several Allan liners, has been killed while in command of one of his Majesty's ships.

A. McL. Seeley, for several years general storekeeper of the Nova Scotia Steel & Coal Co., at Sidney Mines, has been appointed to the position of general purchasing agent, with headquarters at New Glasgow, N.S.

I. J. Tait, formerly chief engineer at the Windsor station, Montreal, has recently become associated with J. T. Farmer, sales representative for the Green Fuel Economizer Co. and the Combustion Engineering Corporation of New York.

J. T. Farmer, 314 Coristine Bldg., Montreal, who for several years has handled the Canadian business of the Green Fuel Economizer Co. of New York, has in addition to this, the agency for Canada, for the Combustion Engineering Corporation also of New York; this firm manufactures a line of underfeed stokers.

S. R. Sheldon, vice-president and chief engineer of Sheldon's Ltd., Galt, Ont., the well known manufacturers of heating and ventilating equipment, died suddenly last Monday after an operation for appendicitis aged 40. Mr. Sheldon was originally with the McEachren Ventilating Co. and about fifteen years ago took over the business with his brother W. O. Sheldon. The company was at a later date incorporated as Sheldons Ltd.

TRADE GOSSIP

Montreal, Que.—Pulp mills of D'Alma Peribonka Pulp Co., at St. Joseph D'Alma, Lake St. John, has been sold to R. W. Barclay of Montreal and V. N. Theriault, of Nicolet, for about $100,000.

Mackinnon, Holmes & Co., Sherbrooke, Que., have recently received an order for a quantity of steel bow plates to be used in connection with troop scows being built in Canada.

Extend Time for Loading.—The Standard Shipping Co. of Cleveland, Ohio, has arranged with the Canadian shippers to extend opening shipping period five days and boats loading to Fort William and Port Arthur will have fifteen days instead of ten days to report for cargoes.

Montreal, Que.—It is understood that the Aetna Chemical Co. of Drummondville have been advanced $1,000,000 by the Imperial Munitions Board to serve as additional working capital. The Munitions Board have also agreed to increase the price of smokeless powder to 57 cents a pound.

Big Increase In Customs Returns.—Hon. J. D. Reid, Minister of Customs, announced to-day that the Customs revenue for April was $14,149,156, compared with $10,346,572 for April of last year, an increase of $3,802,584. The increase noted is the largest for any month from Customs in the history of the country.

The Metal Manufacturers Service, have opened an office at 76 Sun Life Building, Toronto as a means of assisting jobbing machine shops in obtaining work. This concern will be glad to hear from owners of machine shops doing jobbing work in regard to size and capacity of their plants, particulars of machinery installed and class of work for which the shop is best adapted, number of mechanics employed and if they can take on any more work for early delivery.

Returns From Excise Duties Decline.—Receipts of the Inland Revenue Department during March last amounted to $2,020,749, as compared with $2,273,124 in the same month in 1916, a decrease of $253,000, probably accounted for by the enactment of prohibitory laws in several provinces. Of the collections, $1,819,135 represented the proceeds of excise duties. This included $698,527 from taxes on spirits, $10,043 from malt liquors, $157,525 from malt, $869,938 from tobacco, and $63,115 from cigars. War tax collections in the department amounted to $136,056 during the month.

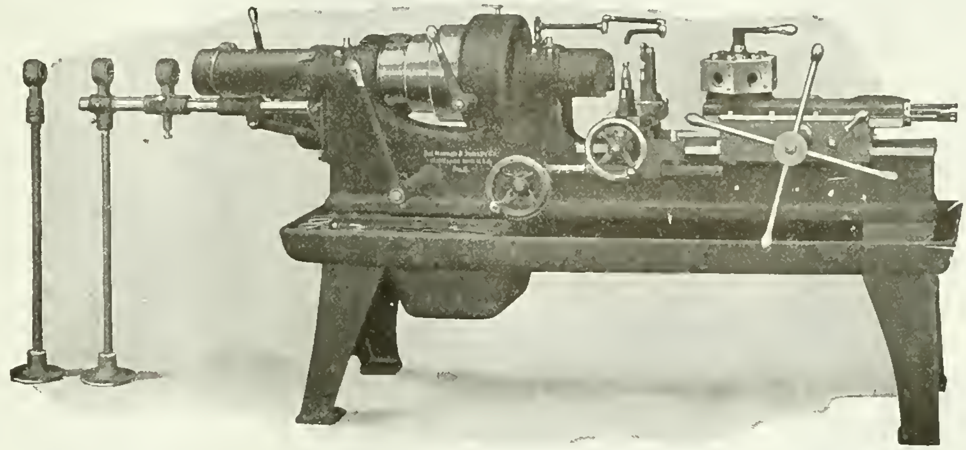
Shortage of Tin Plate Affects Canneries.—Canadian canning factories are concerned over the fact that they have to depend on American companies to furnish the cans, and that this year the supply of cans in the conservation of tin, is much less than usual. American canneries are able to obtain only 40 per cent. of their usual requirements, and are intending to can only perishable goods. Where the Canadian factories will come off is not yet known exactly, but they, too, will probably be able to use tins only for exceedingly perishable products. Cardboard paper machine and other manufactured containers are being suggested for some lines.

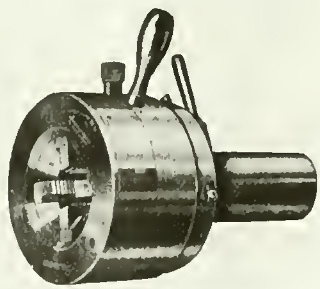
Work on Welland Canal Ceases.—Work on the Welland Ship Canal was completely closed down on May 2, when the services of all the engineers' staff were dispensed with. Including those of J. L. Weller, engineer in charge to whose initiative the building of this great work is due. The contracts for four sections, comprising about eleven miles of canal, and all the seven lift locks and amounting to about $25,000,000, are about half completed. The contractors were instructed last January to close down all their works for a period of one year and at the end of that time a further period of closing down would probably be specified.

C.P.R. Orders Boats.—C.P.R. tonnage will soon be practically the same as before the war, and four additional ships will be placed on the stocks. The C.P.R. purchased at a cost of $240,000 an ocean steamship of 9,400 tons carrying capacity, and a speed of thirteen knots, now under construction at Newcastle-on-Tyne. The ship will be delivered in July or August, and will make the tonnage of the company's ocean fleet practically the same as it was before the outbreak of war. In addition, however, the company has ordered two steamships of 605 feet in length, with a speed of twenty knots, and two more steamships of 546 feet in length, and a speed of sixteen knots, under a contract with John Brown & Co., Fairfield Shipbuilding Co., and Harland & Wolff.

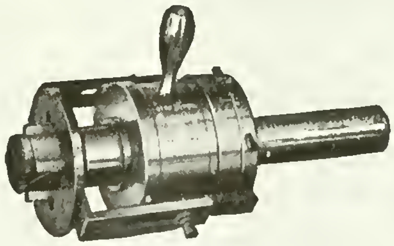
Canadian Canals Traffic Increase.—A Government blue book tabled in the House at Ottawa on May 7, shows that there was an increase of 8,384,688 tons in traffic through Canadian canals during the season of 1916. The total volume of traffic last season was 23,583,491 tons, as against 15,198,803 in 1915. A great increase was shown in the traffic through the canal at Sault Ste. Marie. The total traffic through this waterway during the season of 1916 was 16,813,649 tons, as against 7,750,957 during the previous year. The traffic through the St. Lawrence canals during 1916 totalled 3,368,064 tons, and through the Welland Canal 2,544,964 tons. The total volume of wheat moved through the Soo Canal last season was 185,003,667 bushels, and of this quantity 82,807,342 bushels passed through the Canadian channel. The larger accommodation on the St. Mary's side of the river, says the report, probably accounts for the larger portion of the traffic going through the American channel.

Government Can Requisition Ships.—An Order-in-Council widening the powers of the Canadian Government to requisition ships under the authority of the War Measures Act is contained in a return tabled in the Commons on April





Geometric Self-opening and Adjustable Screw-cutting Die Head.



Geometric Adjustable Collapsing Tap.

30. This order supersedes two earlier ones which were passed on November 24, 1916, and March 31, 1917. The order passed on April 24, provides that any vessel of Canadian registry, any ship under construction or to be constructed, even if exportation for foreign registry has been authorized, may be requisitioned by or on behalf of His Majesty for any purpose whatsoever. The new order also enacts that cargo space on any British ship registered in Canada may be requisitioned, in whole or in part, for any purpose whatsoever.

Old Machinery in Demand.—A Sarnia, Ont., despatch states that war conditions have created a demand for marine machinery of every description and boats which have been in marine graveyards for years are now being raised and stripped of their machinery, which is finding a ready market. Vessel men who long ago had charged their wrecks up to profit and loss are receiving large sums for abandoned machinery. During the last week at this port engines from the steam barge Benson, the tugs Constitution and Bielman, which have been on the bottom for years, have been recovered and they are in good shape. The Bielman's engine goes to New York and those from the Benson and Constitution to Cleveland. engine of the burned steamer Majestic, which was salvaged by the Reid Wrecking Co., also has ben sold. Eastern vessel men say they have scoured every port for abandoned machinery. Plants which have been manufacturing small engines are now engaged in munition business, which is the reason why the old engines are in demand.

TENDERS

St. Lambert, Que.—Tenders will be received up to May 28, for the supply and installation of a horizontal shaft centrifugal pump, electric motor and switchboard. Specifications may be obtained from H. A. Gibeau, town engineer, St. Lambert, Chambly Co., P.Q.

Toronto, Ont.—Tenders will be received at this department up to May 16, for the building of a canning factory at the Experimental Fruit Station, Jordan Harbor. Plans can be seen at the office of the director, Jordan Harbor, and at this department. H. F. M'Naughten, Secretary Public Works Dept., Toronto.

Trenton, Ont.—Tenders will be received until May 15, for the erection of a nine-roomed Collegiate Institute in the town of Trenton, Ont. Plans and specifications may be seen at the Architect's office or at the office of C. W. Saylor, Chairman of Committee, Trenton. All information, tender forms, etc., may be had at the office of S. B. Coon and Son, Architects, Excelsior Life Building, Toronto Street, Toronto.

Winnipeg, Man.—Tenders for the additions to the city light and power plant at Point du Bois, decided on in January by the city council, are to be called at once and will close May 15, so that no time will be lost in taking advantage of the summer working season. The new work which will include the installing of generators sufficient to carry the constantly increasing load for many years to come, will cost approximately $180,000.

Dungannon, Ont.—Tenders, addressed to the undersigned, will be received up to May 12, for the material, plant and equipment of the Ontario West Shore Railway between Goderich and Kincardine. The material is practically all on the right-of-way, and consists approximately of six pairs of steel bridge girders for bridges of 25 ft. to 70 ft. spans; 2,400 cedar fence posts, 8 ft.; 710 boxes of spikes (about 324 lbs. to box); 135 boxes of bolts (about 125 lbs. to box; a large quantity of fish-plates; one engine, three flat-cars, scrapers, etc., used in construction work; a quantity of square timber, from 8 ft. to 24 ft. long; about 2,000 feet of 2 in. hardwood plank; about 900 tons of 70-lb. steel rails; also fourteen miles of track of 70-lb rails, bolts, spikes, fish-plates, ties, bridges, etc., laid complete. For further particulars apply to the trustee, Thomas Stothers, Dungannon, Ont.

MARINE

Port Colborne, Ont.—Dewitt Carter, president of the Welland Canal Tug Co., has completed the sale of the two tugs, Alert and Escort, to the Montreal Transportation Co. The tugs will continue towing in the Welland canal.

Captain R. C. Brown, of the Donaldson liner Cassandra, received the Harbor Commissioners' gold-headed cane, by reason of his having opened the 1917 season of ocean navigation to Montreal on May 1, his vessel coming into port early on that date.

Victoria, B.C.—Work is progressing rapidly on the G.T.P. steamer Prince Rupert at Esquimalt, where the vessel is drydocked. Messrs. Yarrows, Ltd., have a large gang of men at work and the steamship will be made ready for service again as quickly as possible.

St. Catherines, Ont.—Str. Natironco, owned by A. B. McKay of Hamilton, on May 3 carried away two head gates of Lock 3, Welland Canal. The freighter was upward bound when something went wrong with the engine. The damage is estimated at between $2,000 and $3,000.

St. Catharines, Ont.—The steamer Natironco, owned by A. B. McKay, of Hamilton, on May 3, carried away two head gates of Lock 3, Welland Canal. The freighter was upward bound when something went wrong with the engine. The damage is estimated at between $2,000 and $3,000. The pairs were completed on the head gates on May 4, and traffic resumed.

Steamer "G. A. Richardson" Sold.—Marvin M. Marcus, vice-president of the Great Lakes Transit Corporation, in charge of finance, announces that he has sold the steamer Granville A. Richardson to the Lake Transportation Co. of Mentor, Ohio, with offices in Cleveland. James Playfair, of Midland, Ont., is president and general manager of the company.

The Richardson has been at Buffalo fitting out ready for service.

Ships of Ferro Concrete.—Advices from Norway say that an experiment is about to be made with two motor ships, the hulls of which are constructed of ferro-concrete, to test the fitness of such vessels for North Sea trade. The boats will be of 1,000 tons and 600 tons, respectively. Ferro-concrete lighters have been used successfully for some time in Swedish coast traffic. The Norwegian boats can be built in four or five months and are cheaper than those of steel or wood.

Brockville, Ont.—In the presence of 1,000 spectators the new excursion steamer John Webster was about to be launched at Morristown, when the cribbing of the ways slipped as the new craft was fifteen feet toward the river. The boat settled on land, and all efforts to release it failed. The boat was christened by Miss Clara Garvin, and short speeches were delivered by Mayor Wright, W. A. Lewis, Brockville; A. W. Gregory, F. W. Ames, J. V. Crawford, R. Nicolson and Rev. Mr. Hay, of Morristown. The Webster was built at a cost of $25,000, and is named after Brockville's Federal member. She is 106 feet over all and 26 feet beam. On May 4, success attended the launching effort.

Less Meat on Ships.—Members of the Lake Carriers' Association are to do their part toward conservation of the food supply by urging greater economy in the use of foodstuffs on their vessels. A circular prepared by President William Livingstone, and sent to members of the Association, is being transmitted to their vessels. The communication is in part as follows: "The crews of our ships should line up with the housewives of the country, and serve the nation by eliminating all waste of foodstuffs and reducing the consumption of meat. Do you think in these critical times it is necessary to serve meat four times a day, as has become the practice on our lake ships? I appeal to you and to the crews on your ships to practise strict economy by not wasting a particle of food, and intelligently reducing the meat consumption on ships."

CONTRACTS

Regina, Sask.—The Poole Construction Co. has been awarded the contract for erecting a school building at $18,220.

Toronto, Ont.—All the contracts have been let in connection with the $200,000 office building for the Toronto Harbor Commission.

Peterborough, Ont.—The Quaker Oats Co. have awarded the contract for the rebuilding of their factory here, to the Canadian Leonard Construction Co., for $500,000.

Quebec, Que.—The Eastern Canada Steel & Iron Works of St. Malo, have been awarded the contract for the steel work for the grain storage building for the Quebec Harbor Commissioners. The contract price is $275,000. The George Fuller Co., are the general contractors.

The Ford-Smith Machine Co., Hamilton, Ont., have received an order from Alfred Herbert, Ltd., of Coventry, England, for seventeen milling machines, twelve No. 2, and five No. 3 millers. This is a repeat order and was placed on account of the very satisfactory service given by the machines on the original order, in aeroplane and automobile factories in Great Britain and France. The machines before acceptance were subjected to a rigid examination.

Shipping Board for Canada.—Legislation, with object of promoting and making permanent the shipbuilding industry in Canada, is to be brought down by the Government this session. At present Canadian shipyards are working to full capacity, but the orders placed through the Munitions Board are more essentially due to the urgent situation now existing. What is proposed is a plan which would make for the permanent maintenance of the industry by a programme of Government assistance through loans or subsidies. Quite probably a shipping board will be created to assume general direction of the scheme.

RAILWAYS—BRIDGES

Toronto, Ont.—The Dominion Railway Board has issued a judgment in favor of the C.P.R. application to be allowed to build a double-deck bridge over the Summerhill avenue ravine.

Lethbridge, Alta.—Engineers for the Alberta-Hudson railway are now working in the south, on preliminary routes for the proposed extensions of the line, a charter for which was granted at the last session of the legislature, R. D. Fry is the engineer in charge in the south and has already run preliminary surveys for the proposed line from Pincher Creek to Cardston, thence to Coutts and on to Medicine Hat. From a point near Cardston a survey for the line into into Lethbridge will be made.

CATALOGUES

Universal Turret Lathe.—Catalogue just off the press describes the No. 1 Universal turret lathe made by the Foster Machine Co., Elkhart, Ind. The catalogue contains a full description of this turret lathe together with complete specification and illustrations showing the general design of its principal features. The tools and attachments used on this machine are also illustrated and fully described.

"Diamond Soot Blowers for Babcock & Wilcox Boilers." is the title of the attractive and interesting Bulletin-125 just recently issued by the Diamond Power Specialty Co., of Detroit, Mich. It contains the statement from the Babcock & Wilcox Co., explaining why that company has adopted "Diamond" soot blowers as standard equipment for all boilers it builds. The descriptive matter regarding the application of the mechanical soot blower to B. & W. boilers is clearly illustrated by pictures and drawings. The installation of mechanical soot blowers on the 2365 h.p. double Stirling boilers at the Detroit Edison Co.'s Connors Creek plant is one of many interesting illustrations shown. A copy of the bulletin will be sent free to anyone requesting it.

Whiting Cranes.—Of all types and for every service are described and illustrated in catalogue 127 recently issued by the Whiting Foundry Equipment Co., Harvey, Ill. The opening pages of the catalogue deal with electric traveling cranes illustrating and describing the latest features in Whiting crane construction. Following are brief descriptions of hand power, locomotive and cranes accompanied by illustrations showing the various types. The second half of the catalogue shows several typical illustrations of whiting cranes of various sizes and capacities in different classes of service. These views represent a wide field of service covered and are shown with the object of assisting purchasers to select the proper types.

Modern Steam Disinfection is the title of a catalogue issued by the Grampian Engineering Co., Stirling, Scotland, and featuring the "Velox" steam disinfectors for hospitals and military camps, etc. The catalogue is arranged in two main sections. The first part compares various methods of physical disinfection explaining the development of the steam process and its principal features. Then follows a full description of the "Velox" apparatus including details of construction covering both high and low pressure disinfectors. The combined high-pressure steam and vacuum-formalin process is then dealt with fully with method of operation. The second part of the catalogue contains a representative list of standard types and sizes of the "Velox" steam and combined disinfectors. The various types, stationary, portable and marine are described and illustrated; the class of work for which each type is recommended. A report of tests concludes a well arranged catalogue.

Abrasive Grinding Wheels is the title of an attractive new catalogue No. 6, issued by Abrasive Company, Philadelphia, Pa. The catalogue contains an extensive list of special shaped abrasive grinding wheels for miscellaneous grinding machines. The wheels are classified and illustrated with principal dimensions and price given for each size. Straight, cup and cylinder wheels are also listed, accompanied by rules for calculating list prices. A chapter is devoted to the use and care of wheels, followed by a set of rules for calculating speeds. The principal points involved in the process of manufacture of these wheels, which are made of boro-carbone and electrolon, are briefly described. A table for selection of grain and grade for various classes of work is a useful feature of the catalogue and one of considerable help when ordering. The catalogue contains telegraph and cable codes and general index. Copies may be obtained from the Canadian distributors, the Canadian B.-K. Morton Co., Toronto and Montreal.

Gun-Crete.—The Cement-Gun Construction Co., Chicago, Ill., have issued a bulletin No. 5 containing a number of illustrations of "Gun-Crete" work which they have executed. The bulletin explains what Gun-Crete is and the method of application while the illustrations show the wide range of work where it has been used.

Fifteen Years on Brine Lines is the title of a bulletin being distributed to the trade by the Armstrong Cork and Insulation Co., Pittsburgh, Pa. The bulletin refers to a number of instances as indicated by the title and explains the saving in refrigeration on this account. Copies may be obtained from the Canadian office of the company, 504 McGill Building, Montreal.

Drilling Machines.—Catalogue dealing with an interesting line of high speed, belt driven, ball-bearing, drilling machines. Each type is illustrated and specifications give the principal dimensions and other particulars. The concluding page contains important notes for the guidance of purchasers. The catalog is issued by the Langelier Manufacturing Co., Providence, R.I.

Hill Clutch Equipment is the title of a bulletin, the first of a series, describing and illustrating installations of friction clutches, collar oiling bearings, rope drives, etc., the product of the Hill Clutch Co., Cleveland, Ohio. This bulletin, April issue, deals with a complete installation of moderate power distribution made by the company, accompanied by interior views of the factory. Copies of the series will be gladly sent to readers interested in power transmission machinery equipments upon receipt of name and address.

BOOK REVIEWS

The British Dominions Year Book 1917.—Published by the British Dominions General Insurance Co., Ltd., London, England. The year book for 1917 contains as usual a number of interesting articles contributed by well known writers covering the great war and matters affecting the well-being of the British Empire. The subjects have been carefully chosen and are particularly appropriate at the present time in that they deal with questions connected with both the military and economic aspect of the situation. Without making any invidious distinctions the following may be mentioned as being a few of the more interesting subjects dealt with. The Aftermath of the War; The War's Three Phases, A Year of Naval War, India's Future in the Empire, Foreign Policy, International Law, Agricultural Outlook, War Finance, National Insurance, Aircraft in the War, etc. In addition to the main subjects the Year Book contains other interesting matter of diverse nature including numerous statistics and reports. The book contains 308 pages with a number of colored plates inter-leaved and shows orders and decorations, regimental colors, house flags and several maps.

Over the Page

you'll find a number of small items, some of which will most certainly interest you. Every week there are opportunities galore offered there.

Rates (payable in advance): Two cents per word first insertion; one cent per word subsequent insertions. Count five words when box number is required. Each figure counts as one word. Minimum order $1.00. Display rates on application.

FOR SALE

ONE 20 H.P. MOTOR, IN GOOD CONDITION. Spartan Machine Co., Lt., 1112 St. Patrick St., Montreal. c21m

FOR SALE.—ONE 8 x 8 AIR COMPRESSOR with unloader and reservoir complete.—Apply Canadian Hart Wheels, Limited, Hamilton, Ont. c18m

FOR SALE—ONE LEWIS TYPE ENGINE built by Waterous Engine Works, 240 H.P., flywheel 73" x 18", automatic governor, a bargain. One steam pump, 4½" x 2¾" x 4". Write Box 217, Moncton, N.B. c24m

ONE 4.5" LEES-BRADNER THREAD MILLER —in first-class condition. For milling threads in nose of shell. Spartan Machine Co., Ltd., 1112 St. Patrick St., Montreal. c20m

FOR SALE.—ONE 10' BED, 10½" SWING, Crosby SS Screw Cutting Engine Lathe, or will exchange for 40" Gap bed lathe.—Apply Canadian Hart Wheels, Limited, Hamilton, Ont. c18m

1—GISHOLT LATHE 24" SWING, 6' BED, with turret head and three-jaw chuck. 1—Gisholt lathe, same as above, 20" swing, 6' bed. 1—4.5 Brown, Boggs marking machine. Jenckes Machine Co., Sherbrooke, Que. c20m

FOR SALE—ONE 450 H.P. THOMPSON & Williams condensing engine. Will sell cheap. Engine is in first-class repair and will give every satisfaction. Apply J. A. Marven, Limited, Moncton, N.B. tcfm

ONE LATHE 16" x 4½' BACK-GEARED — Built by P. P. Silk Machine & Tool Co., Cincinnati, Ohio. One lathe 18" x 3', back-geared. Built by the Bradford Mill Co., Cincinnati, Ohio. Four Murchey collapsible dies. Capacity 1½" to 2½". Box 272, Canadian Machinery. ctmf

1 16" x 14" "WATERTOWN," CENTER crank, four-valve engine; flywheel 66" diameter, 14" face; direct connected to 100 K.W., 6 pole, 220 volt General Electric direct current generator, complete with cast iron sub-base under engine; gravity oiling system and force feed lubricator. Delivered f.o.b. cars, Stellarton, N.S., $3,600. The above outfit is in perfect working condition, is as good as new, having been in operation less than two years. Shipment can be made in one week. Albion Machine Co., Limited, New Glasgow, N.S. c21m

1 ENGINE LATHE, 22" SWING, 36" CENTER to center, geared 18 to 1, arranged for shell turning, with two straight turning tools and one profile turning tool. 1 Gisholt lathe, 30" swing, with turret head and chuck. 1 Engine Lathe, 14" swing, 30" long, with steady rest, face plate and countershaft, suitable for screw cutting. 1 Potter & Johnston Automatic Turret Lathe, 19" swing. 1 Turret Gap Lathe, 24" swing over bed, 40" over gap, 9' long over all, with turret for six tools. 1 Power-driven Plate Planer, 9' 9" long, screw feed. 1 Brown, Boggs Marking Machine, for 4.5" shell. 1 Band Press, air operated, for 4.5" shell. 3 Sand Blast Tanks. Jenckes Machine Co., Sherbrooke, Que. c20m

WANTED

WANTED—THE ADDRESS OF A MANUFACturer of crude oil or kerosene engines, for export. Semi-Diesel type preferred. Address Box 301, Canadian Machinery. c18m

SUBSTANTIAL LOCATION IS DESIRED FOR an iron working plant, especially where liberal financial assistance can be secured for a worthy enterprise. Address Box 302, Canadian Machinery. c18m

WANTED—WHAT HAVE YOU TO OFFER in heavy turret lathe, suitable for boring 4.5 shells? State whether new or second-hand, maker's name, dimensions, condition of service and equipment if any. Wire reply to Medicine Hat Pump & Brass Mfg. Co., Ltd., Medicine Hat, Alberta. c19m

SPECIAL MACHINERY

MANUFACTURERS—WE CAN UNDERTAKE work to any specification—munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

O. E. WOODS—GENERAL MACHINE SHOP—builders of special machinery. Will do well to use our experience and equipment. We are prepared to make special machinery, punches and dies, jigs, fixtures and tools to any specifications and drawings. Get our price and promise of delivery. Phone Gerrard 960. Address 754 Broadview Ave., Toronto, Ont.

SITUATIONS VACANT

WANTED—GENERAL FOREMAN FOR MAchine shop on 6-inch Mark III. shell production. Must be holding similar position, have initiative and able to push production. To such a man every encouragement will be given. Box 308, Canadian Machinery. c21m

One Advertiser Said To Us—

"One insertion of this ad will do"—when sending in copy for a condensed ad. This firm sends in from three to four ads a month, so they ought to know.

While two or three insertions give your proposition more chance to be considered, still this incident shows just what advertisers know this section will do for them.

Use its service now—every time you need it.

BUSINESS CHANCES

SPLENDID OPPORTUNITY FOR MANUFACturer to locate in town with water and transcontinental railway connections. Large cement factory with equipment and good water power, ready for operation; also large piece of land for extension purposes. To encourage a good, live manufacturing concern, special concessions will be given. All inquiries treated confidential. State nature of business when replying. Apply P.O. Box 533, Montreal. c19m

FOR SALE—A MEDIUM-SIZED TWO-STOREY brick factory situated in the best small city in Ontario. Buildings in good condition, suitable for either metal or wood-working; shipping facilities unexcelled. Two trunk lines; direct connections east, west, north and south. Educational advantages the very best. Plant will be sold at a bargain and on easy terms of payment, if desired. Apply Box 294, Canadian Machinery.

SITUATIONS WANTED

WANTED—POSITION AS PURCHASING MAN or salesman. Have thorough knowledge of hardware, mill supplies, carbon and high speed steels, tools etc.; age 34; married; ambitious.—Box No. 307, Canadian Machinery. c20m

STEEL FOUNDRY EXECUTIVE, CANADIAN, with fifteen years' experience with most up-to-date plants in United States, seeks similar position in Canada. Thoroughly conversant with sales, operation and business management. Box 306, Canadian Machinery. c22m

PRACTICAL WORKS MANAGER AND MEchanical expert with years of experience in United States and Canada, a specialist in munition work, open for engagement. Best of references. Apply Box 304, Canadian Machinery. c23m

ELECTRICAL ENGINEER—COLLEGE GRADUate, five years' practical experience; now employed in large industrial plant, electric-driven; responsible position desired; money not sole object; recommendations. Box 305, Canadian Machinery. c21m

SITUATIONS VACANT

FOREMAN PATTERNMAKER—MUST BE OF first-class; man experienced on engine, mining and general contracting machinery patterns. Write fully, Box 298, Canadian Machinery. ctmf

WANTED—SALESMEN TO SELL BABBITT metals on commission as side line. Good commission. Give full particulars as to firms represented and territory covered. Box 303, Canadian Machinery. c21m

MECHANICAL ENGINEER WANTED—FIRST-class opportunity for the right party. Must be energetic, ambitious, sober and have some knowledge of French. Apply Box 286, Canadian Machinery. tcmf

TOOL STEEL SALESMAN — ONE WITH knowledge of the business preferred. State age, whether married or single, experience. No application will be considered unless full details are given. Box 300, Canadian Machinery. c20m

A GOOD SALES ENGINEER TO OPEN OFfice to sell Moline heat in Canadian territory. Must be a good salesman, having had a general heating and ventilating experience. Must give good references. We have a fine proposition for the right man. Address Moline Heat, Moline, Ill. ctmf

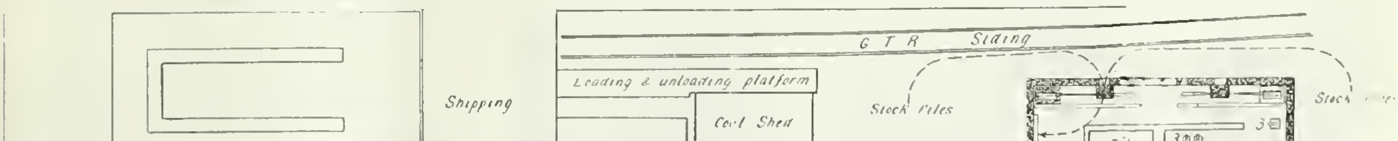
Equipment, Methods and Devices for Machining 6 in. Shell

Staff Article

Shell production still holds the premier place in the activities of our metal-working industries, although, in the case of the 8-inch and 9.2-inch sizes of high explosive, a marked falling off in the demand and consequent receipt of contract renewals has for several weeks been in evidence. Machining 6-inch shell is believed to have taxed executive skill and capacity to a greater extent than has any other of the variety projectile manufactured by us, in consequence, successful achievement as exemplified here is all the more meritorious.

PRODUCTION of shell on a vast manufacturing basis has become so well established throughout the Dominion that it would seem impossible to describe the machining of any type of shell that has not already received notable mention in these pages. However, the varied enterprise that large numbers of our mechanical men have had occasion to demonstrate in a practical way to procure rapid and successful manufactures of the varied size and type shell called for, has developed much inventive genius and latent individual resourcefulness, so much so that the methods adopted in different shops for the achievement of the same object vary in large degree, with the exception perhaps of some of the more common machining operations.

In relating the practice that has been adopted in the plant from which the accompanying data were secured, it is not the intention to describe in detail the complete sequence of operations, but rather to dwell on those that are in a measure, local, so to speak. Past ex-

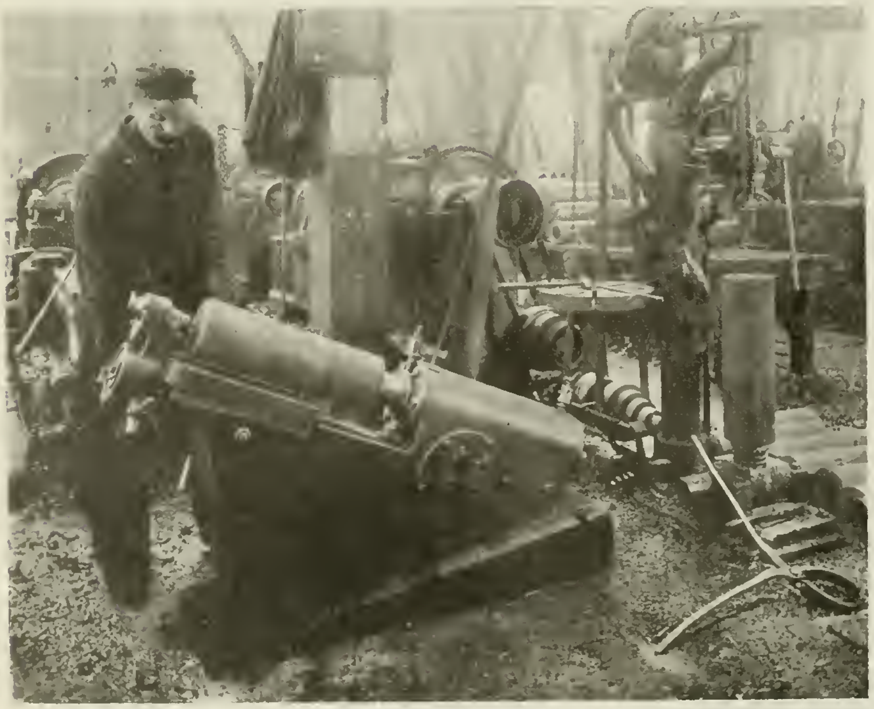


LAYOUT OF 6-INCH HIGH EXPLOSIVE SHELL MACHINING PLANT.

perience has clearly demonstrated that one of the first things to consider when going into the manufacture of any type of shell, is the layout of the necessary equipment in as convenient a manner as possible, so that the minimum amount of handling of material will enable the progress of the shells to be entirely free from any "backing up," as they are transferred from one operation to another. While ideal conditions in this respect are not always possible, it is very essential that careful attention be given to these fundamental details when placing the machinery, if satisfactory progress is to be maintained. Where an old plant must be utilized for the placing of the additional equipment that is involved by the many machining operations on shell bodies, it is often a difficult problem to plan a suitable layout, particularly where the machines must be crowded to meet the desired amount of output; but in cases where new additions are necessary it is very desirable to construct the plant with the progressive movement as the basis of output; in other words, to first plot a machine tool layout (with plenty of room for possible expansion on doubtful operations), and then build the shop around the layout. In the case of the plant here described, an output of approximately 400 six inch shell per day was determined, to accomplish which it was necessary to increase the floor space to secure sufficient room for additional equipment. After several trial layouts, the one here illustrated was finally adopted, requiring the addition as shown to the right of the ground plan of the machine positions. This building is of concrete and brick construction, 160 feet long and 60 feet wide, having saw-tooth roof and being hot air heated. The floor space amounting to about 9025 square feet. With a view of providing the best possible lighting, the roof was constructed so that the light enters from the north, thus eliminating the glare of the sun during the greater portion of the day. The plant is very favorably located as regards the receiving of raw materials and the shipping of the finished products, adjoining as it does the main line of the G.T.R., and having a convenient siding along one end of the shop, where a platform 60 feet long offers desirable facilities for the loading and unloading of billets and shells.

GERARD CUTTING-OFF MACHINES.

GENERAL VIEW OF SECTION OF SHELL SHOP.



VICTORIA FOUNDRY CO. MACHINE FOR CENTERING BASE OF SHELLS.

Rough Facing Bottom of Bore

As the billets are received from the cars, they are placed in stock piles adjacent to the rear of the new building, and when required for use are transferred to the shop through suitable openings in the walls and thence to the first operation of rough facing the bottom of the bore. This detail was deemed advisable so that a reliable base could be secured from which to gauge the subsequent operations. As no particular accuracy is required at this stage, the machining is done with a floating cutter that will accomodate itself to the irregularities of the bore and yet produce a clean smooth base. The maximum cutting speed is 40 feet per minute and a production of 12 per hour is maintained on each machine, the feed being obtained from a cam. The tools used for this operation are shown by (1) on the operation chart. It might be stated here that for all boring operations, a standard machine steel boring bar has been provided, and with the exception of the turret shank, they are identical in every particular. The details of this bar are shown in the upper right hand section of the operation chart, the cutter heads being held in position by means of a key passing through the end of the bar and the shank of the tool holder.

Cutting Off Open End

Cutting off the open end is performed on five Gerard cutting off machines. The latter are provided with a revolving cutter head while the shells are held stationary in a chuck attached to the saddle of the machine. For centering the base end, an interesting machine shown herewith is used: this tool being made by the Victoria Foundry Co., of Ottawa, and being specially designed for the purpose. Integral with the extra heavy base is the main bearing that carries the spindle and also the work arbor, the latter being an extension of the former. The position of the spindle is approximately 30 degrees off the horizontal, and provision is made in the mandrel to grip the shell bore central with the machine arbor and retain it in a rigid position as it is revolved. On the bed of the machine below the arbor, ways are provided that support the carriage which can be moved laterally and parallel to the axis of the spindle by means of a rack and pinion. On the outer end of the carriage ,a swivel arm is fitted which can be swung clear when

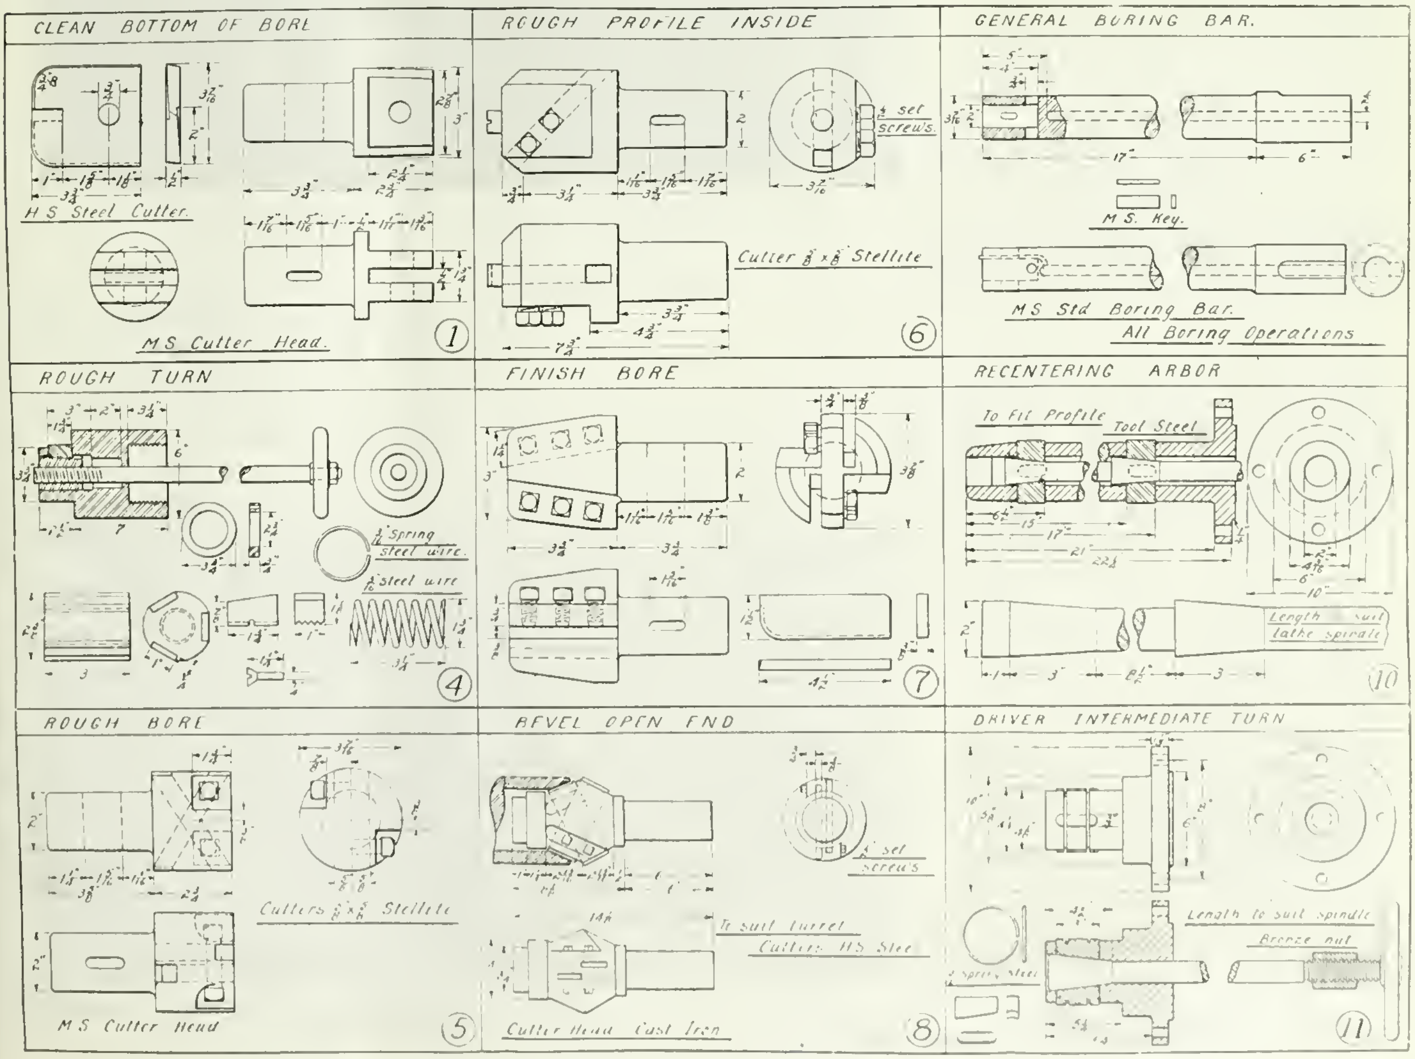
ROUGH BORING SHELL NOSE ON FOUR-SPINDLE DRILL.

the shell is being placed on or being taken off the arbor. When in a working position, the center of the drill holder is in the axial line of the machine spindle, and likewise the shell bore. The feed of the drill is obtained by a hand wheel located at the opposite end of the pinion shaft. The angular position of the supporting arbor provides a convenient method of holding the shell, the weight of the shell acting as a semi-automatic means of operating the expanding arbor. The production from one of these machine averages about 120 in ten hours.

Rough Turning

Rough turning is accomplished in a very similar manner to that of other shops, the details of the driving arbor being shown at (2) on the operation chart; each machine has an output of six shells per hour. For roughing out the bore, the special cutter head shown in section (5) of the operation chart is employed. Stellite, 5/8 inch square is used for cutters. The diameter of the large section of the head is 3 7-16 inches, with a tool overhang of about 3/4 of an inch. At a cutting speed of 60 feet per minute the production from each machine is about 7 per hour. Roughing out the base profile is performed in a separate operation; the cutter head used being shown in section (6) of the operation chart.

An arrangement of the Dawson boring machine used for boring and roughing the inside base profile is shown in drawing on page 502. The driving pulleys are located on the shaft A.



TOOL CHART, 6-INCH HIGH EXPLOSIVE SHELL MACHINING.

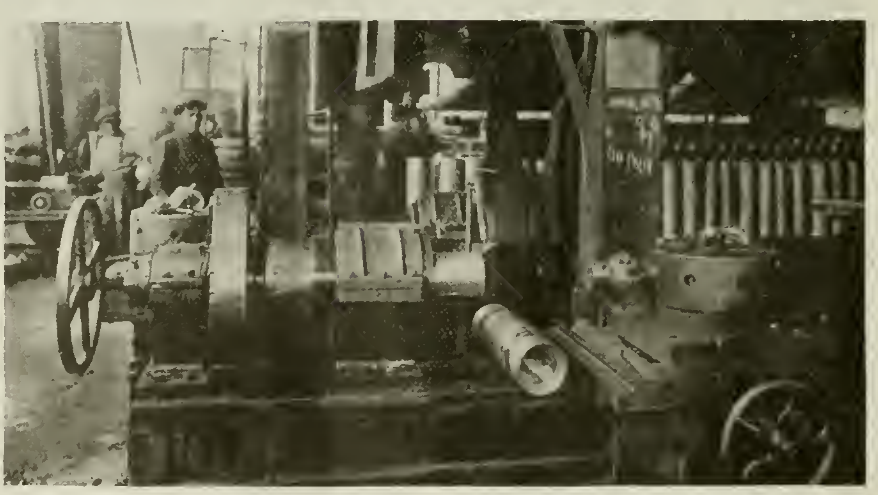
MACHINE OPERATION CHART.

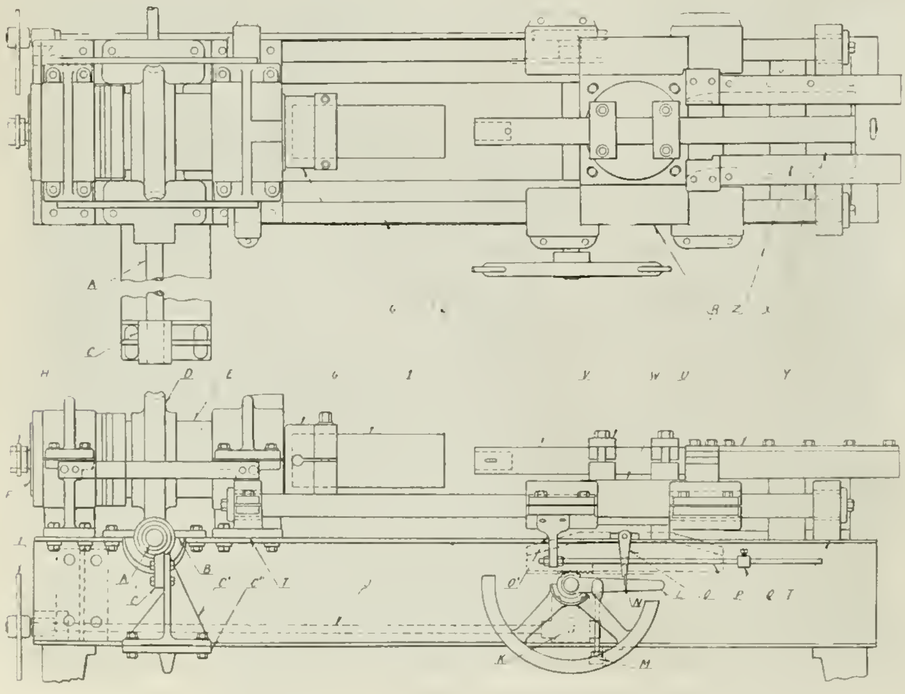
which is supported at right angles, and below the main spindle, in the two brackets B, one on either side of the machine; the outer end of the driving shaft being supported in the tail bracket C, which in turn is secured to the bracket C^1 bolted to the casting C^{11}, extending out from the bed of the machine. A worm on the shaft A engages with the large worm gear D which is secured to the main spindle E, the latter revolving in special bronze bushings F in both the front and rear bearings. Fitted to the front of the spindle is the spring chuck G that grips the base end of the shell, the forward end running in a suitable steadv head. By means of a chain drive on the sprockets H and I, the feed shaft operates the mechanism contained in the saddle of the lathe.

By pushing down on the handle L, the worm box is lifted, bringing the worm in mesh with the worm gear which is located on the opposite end of the hand wheel shaft, the pinion operating the carriage being secured to the middle of the shaft so that a central drive is obtained, thus eliminating any side pull upon the saddle, and insuring a uniform thrust upon the cutting tools. The handle L is in a convenient position to the operator while the worm box K is located at the rear of the lathe, the connection being made by means of a cross lever pivoted in the center of the lathe bed. When the worm and gear are in mesh, the handle L is locked by the dog N fitted in the end of the swing piece O. The feed can be disengaged at any desired point by adjusting the position of the collar Q on the rod P, so that it will trip the piece O and allow the worm to fall from a working position.

The carriage R travels on the shafts S, one of these being placed on either side of the machine and being supported at each end by the brackets T T. The turret U is provided with two housings in which the boring bar V is secured by the clamps W. On the rear end of the bar the guide piece X is located, this piece controlling the movement of the forward end in its passage through the bore, the cam plates Z being shaped at the end adjoining the turret so that the cutting tool will cut the desired shape of base profile. Stellite tools are used on this operation, and a stop is placed in the end of the cutter head to gauge the depth of the cut when the tool is in the extreme bore of the shell.



BEVELLING OPEN END WITH SPECIAL TOOL-HOLDER, GERARD TURRET.



ARRANGEMENT OF DAWSON BORING MACHINE.

Finishing the Bore

The tool used for finishing the bore is shown in section (7) of the operation chart. It has been the practice in this shop, as far as possible, to provide tools that would require the minimum amount of skilled labor in the maintenance of their efficiency. As shown in the sketch, the cutter head is shaped to an angle so that straight portions of steel can be used to bring the cutting edges to the desired dimensions, with the exception of the nose radius and the small portion that sizes the finished bore of the shell; these being shaped after the steel is secured in position. At this operation, the bore is finished to 4.24 inches diameter and to an overall depth from the open end of 19½ inches.

Beveling Open End

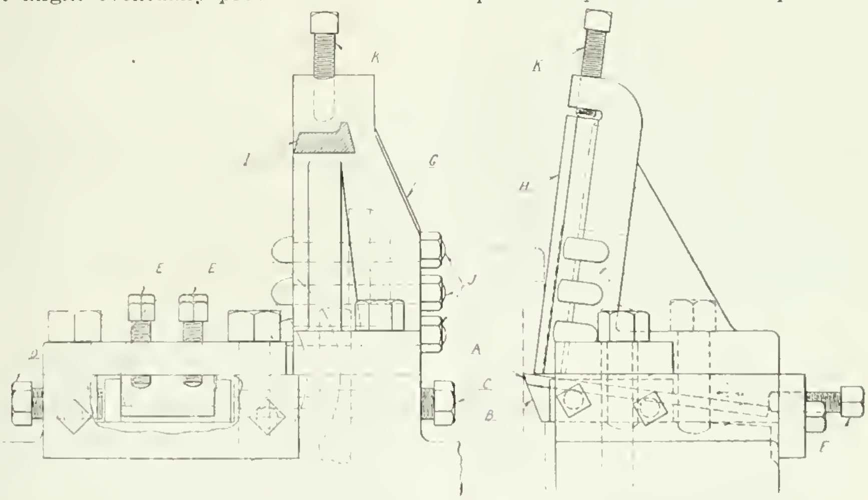
A cheap yet highly effective cutter head has been designed for beveling the open end previous to closing in the nose.

BATTERY OF FINISH TURNING LATHES.

This head is shown in section (8) of the operation chart and is made of cast iron; the holes for the cutters being rough cored, no machining being necessary on this particular portion of the head. The shank, of course, as well as the gauging collar, is turned to the desired dimensions and screw holes drilled for clamping the tools in position. The cored holes are placed in such a position that the cutting face of the tools are ground at right angles to the length of the stock so that little difficulty is experienced in maintaining their efficiency. The dimensions of this beveled portion are a large diameter of 5 9-16 inches tapering to the bore of the shell, and having a depth parallel with the axis of 1½ inches. After the base has been faced off and the end recentered, the shells are given another rough turn at a cutting speed of 120 feet per minute, with a feed of ⅛ inch, the depth of cut being about 1-32 inch.

Interior Grinding

Before passing to the nosing operation, the shell are all carefully inspected for interior finish, as it is important that the surface of the bore should be perfectly smooth and free from ridges that might eventually prove detrimental under firing conditions. Those shells that have developed any roughness through improper machining and are within the specified limits of bore dimensions, are subjected to a grinding process to remove the greater portion of this roughness. A simple fixture has been developed for this purpose and is shown herewith; it consists of a rapidly revolved spindle to which are fixed spring arms carrying small pieces of grinding material to bear on the surface of the bore while the shell is held in a suitable carriage. The extension of the spindle as shown at A is shaped to receive the arms B which are secured to the shaft close up to the headstock. Through the outer end of the extension and also the spring arms, is the small bolt C that allows the arms to move outwards but prevents them from flying out too far when the centrifugal force is set up by the rapidly revolving parts. A fork is provided on the outer end of the arms in which the carborundum blocks are clamped as shown. The carriage that supports the shell is planed out so that, when the shell is in position, the center will be in a line with the axis of the spindle when the carriage is riding upon the supporting rails F. When the shell is placed in position, the clamp is swung over, the end G being shaped so that the handle H when swung upwards will force the clamp down upon the top of the shell. The pressure resulting from the centrifugal force is sufficient to take a good bite upon the surface of the metal.



HOGGING OUT AND FACING BASE.

Nosing-in Process

The nosing-in process, as performed on a 250-lb. Nazel hammer is so satisfactory that a large number of the shells do not require to be further machined on the profile inside the nose. One of these hammers can nose about 300 six inch shells in 10 hours. When the shells come from the nosing hammer, the opening in the end is only about ¾ of an inch in diameter. To enlarge this opening, the shells are placed in fixtures secured to a four spindle drill where the hole is rough drilled with an 1⅝ inch drill, running 65 revolutions per minute, at a feed of 1-16 per revolution, each spindle having an average capacity of about eight shells per hour, one man operating the four spindles. The nose

WAVING AND GROOVING ON BAWDEN LATHE EQUIPPED WITH VICTORIA FOUNDRY CO. ATTACHMENT.

is then faced off in several drill presses, a special facing cutter being used for this purpose. The overall length at this stage is 21¼ inches.

Exterior Finishing

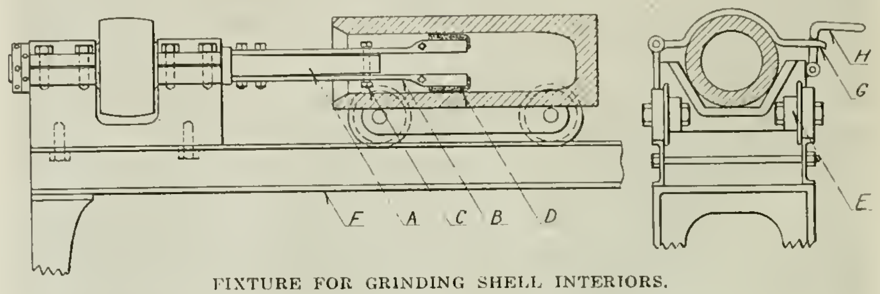
Following the boring and counterboring of the nose, and the machining of the inside profile (if this latter is found necessary), the shells are transported to another department by means of a short conveyor. They now enter upon the second stage of the machining, that of finishing the exterior surfaces. Ten lathes are employed on finishing the body and nose profile, this operation being accomplished in much the same manner as that in vogue in other shops. At a cutting speed of 100 feet per minute and a feed of 1-16 inch per rev., each machine has an output of between four and five per hour; Stevens link attachments are used to machine the nose profile. When the outside has been finished, the base is again faced to bring the shell to the desired weight, care being exercised to keep the length and thickness of the base within the specified limits. The high and low limit at this stage is 85 lbs. 5.7 oz., and 84 lbs. 1.3 oz. respectively, with a mean of 84 lbs. 11.5 oz.

Waving Operation

The tooling for the waving operation is similar to all other methods, but the principle of securing the lateral movement is slightly varied. This is obtained by means of a fixture attached to the back of the saddle, the driving shaft being connected to the gearing at the back of the lathe, and operating through a gear box, the right angle shaft having a small throw crank turned on the end; from this crank a link converts the revolving motion of the fixture into a reciprocating movement of the tool slide. This attachment was made by the Victoria Foundry Co., each machine having an output of about 12 shells per hour.

Roughing Out Base Recess

The machines for roughing out the base recess have a capacity of 15 per hour with a maximum cutting speed of 60 feet per minute. The accompanying photo shows a special Gerard machine on this operation. These lathes are all fitted with special turrets, and the front bearing is of extra heavy design to provide rigid support for the spindle in which is contained the collet chuck for holding the shell. An 8-inch double belt drives the back shaft, the pinion on which meshes with the large gear which is cast integral with the spindle. The chuck is operated by the large hand wheel at the rear of the spindle. A feature on the lathe here shown is the method of feeding the tools into the work. Mounted on channel irons extending out from the bed of the lathe—is an eight inch cylinder, the piston of which is operated by compressed air, the pressure acting to force the cutters into the work being approximately 1 ton. This cylinder being located in the center of the lathe, the thrust is central, thus maintaining more satisfactory work and retaining turret alignment for a longer period. A sketch of the tool set up is also shown; the tool A made of ¼ inch by 2¼ inch high speed steel is used for hogging out the base recess, and is held in the tool block B shaped at the proper angle to give the desired rake to the tool. Lateral adjustment is obtained by the screws C and D, those at the right pushing on distance rods ⅜ inch in diameter. The tool is held firmly by the screws E and adjusted to depth of cut by the tail screw F. An upright casting shaped to give the proper rake to the facing tool H is secured to the back of the same fixture. A section of the Stellite tool is shown at I, this tool being held in position by the three hook bolts J and adjusted to cutting position by the screw K. The base recess is afterwards finished to the exact dimensions with a cutter and floating reamer.

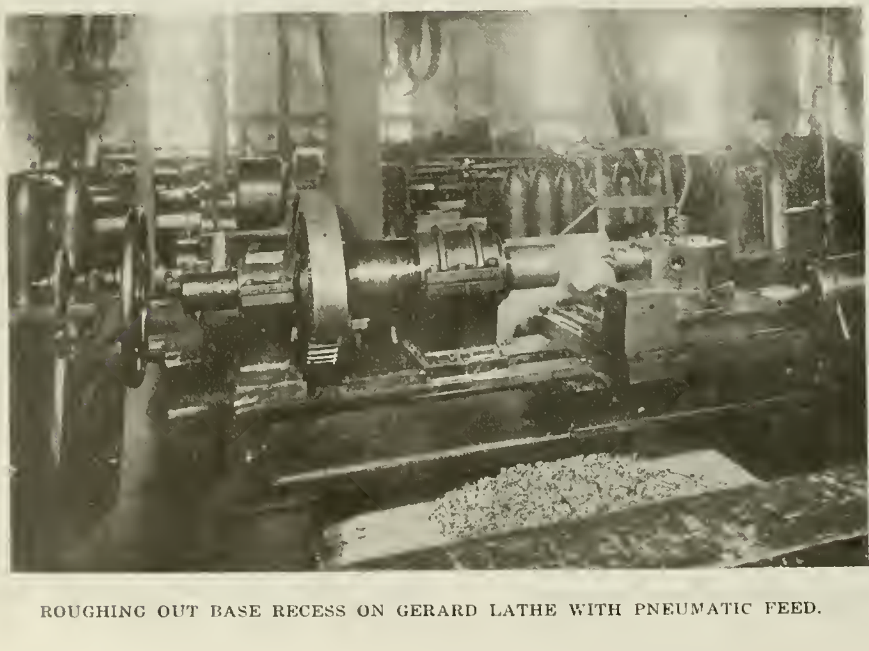


FIXTURE FOR GRINDING SHELL INTERIORS.

Nose Beveling, Recessing and Threading

Before the threads are cut in the nose, the face is beveled and the recess cut in. Two Holden-Morgan milling machines are installed for this operation, each having a capacity of 200 shells every ten hours. Conveyors are used to transfer the shells to and from the base plate riveting operation, which is accomplished in two Rochester high-speed hammers. After facing the base end, the copper bands are pressed on in a Goldie & McCulloch band press, being afterwards machined in lathes fitted with special turning fixtures. The cleaning of the shells, which takes place just after milling the fuse thread, is accomplished by forcing a jet of live steam into the interior and afterwards removing the moisture with a strong blast of compressed air, the heat generated by the action of the steam being sufficient to thoroughly dry the surface of the walls within one minute from the time the shell is removed from position.

A factor in production methods in this plant responsible for much of the successful operation has been the rigid check that has always been enforced in the preliminary shop inspections. These are as rigid as the Government inspection and must be held close enough so that corrections by the Government inspectors will not go above 5 per cent. The final weight of the shell should be 84 lbs. 2 oz. 5 drs., with an allowable variation either way of 10 oz. 2 drs.



ROUGHING OUT BASE RECESS ON GERARD LATHE WITH PNEUMATIC FEED.

Wondered What He'd Say.—The country clergyman was nailing a refractory creeper to a piece of trelliswork near his front gate when he noticed that a small boy stopped and watched him with great attention.

"Well, my young friend," he said, pleased to see the interest he excited, "are you looking out for a hint or two on gardening?"

"No," said the youth, "I be waiting to see what a parson do say when he hammers his thumb."

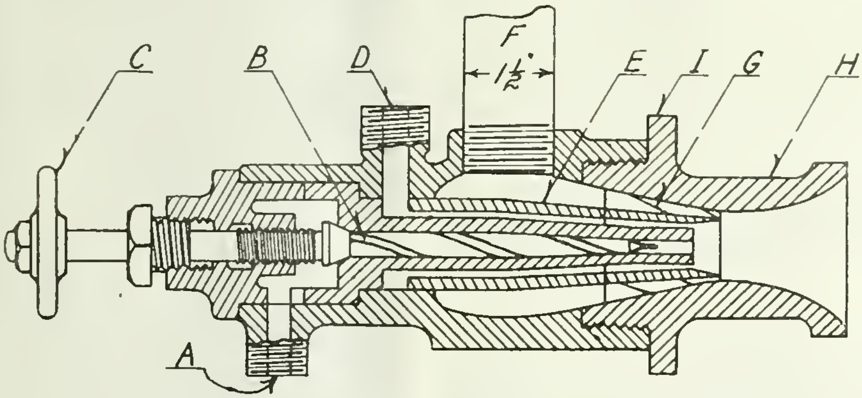
OIL BURNER FOR SHELL FURNACES

By G. Barrett.

IN the process of nosing 4.5 and 6-inch shell, difficulty is often experienced in maintaining proper combustion of the elements when the shells are being heated. This is sometimes owing to insufficient mixing of the oil and air, as they are forced into the fire chamber. To eliminate this objectionable feature, the burner shown in the accompanying sketch was adopted with very satisfactory results. This type of burner is easily applicable to any make of furnace. The oil enters the burner at A, passing through the central chamber where it is given a whirling motion by means of the twisted spindle extension B. This portion is made from round stock and milled flat and then twisted; the amount of oil is controlled by the hand wheel C. The compressed air at a pressure between 40 and 60 pounds enters the opening D through the hollow cone E and around the central tube. The wind from the blower or fan enters the burner through the large pipe F, this pipe being provided with a suitable valve to regulate the quantity of air required. To further assist the mixing of the elements, a spiral cone C is fitted on the inside of the nozzle H. The spread of the flame is obtained by adjusting the position of the nozzle; this being accomplished from the collar I, it having several slots cut around the outer edge. This burner is very efficient, using about 8 gallons of oil per hour.



SECTION OF OIL BURNER FOR BOX FURNACES.

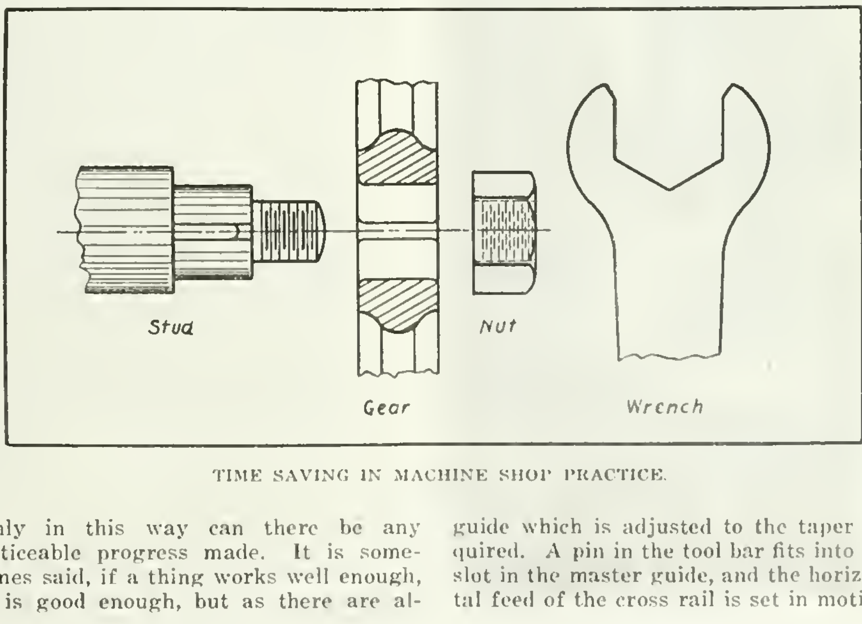
TIME-SAVING IN MACHINE SHOP PRACTICE

by J. E. C.

THERE is another application of the term "time-saving" other than that which has to do with "increased production," "lowering labor costs," "economical processes," etc., to which consideration is suggested. Its particular object may be said to consist in finding out "the better way," "the easier way," or the most "convenient way" of handling tools or work. The saving in time may not necessarily be appreciable. In certain lines of work, particularly of a class that is repeatedly handled over and over again, one notices how little attempt is ever made to render the operations less irksome, or in giving them the proper consideration and study so that they may be more conveniently carried out. If a workman is constantly obliged to handle a screw-driver or a monkey-wrench to unloosen a screw or to unfasten a nut, it is reasonable to believe that, where the application of these is now a practice, a thumb-screw or a thumb-nut would serve the same purpose besides being more convenient and saving handling extra tools.

In order to undertake a study into wasteful methods and inconvenient practices with a view to the elimination of the latter, one needs to do so with a thoroughness and with an "inquisitiveness" in each and every detail relating to any particular machine or operation. Only in this way can there be any noticeable progress made. It is sometimes said, if a thing works well enough, it is good enough, but as there are always "still better ways" in doing a thing, any undertaking in the direction indicated will reveal what these "better ways" are. To demonstrate a simple application of the term "time saving" in the sense already described, an example is given on the well-known operation of changing or putting gears on a lathe. Illustrations are shown for the purpose that they may be examined so one may see where a few little inexpensive conveniences have been adopted.

The key on the "stud" on all lathes is usually made flush with the end on which the gear fits, so that when putting on a gear one must locate the spline exactly before it will engage and slip over the key. If the key is made shorter, the gear can be placed directly on the stud, then turned and a little pressure forces the spline instantly over the key. The key is rounded on the end, as is also the edge of the spline and the hole in the gear hub. The nut which is put on after the gear is fitted, is counterbored out a trifle so that it can be placed over the thread and quickly screwed on. The wrench used in tightening the nut has not been overlooked in these series of conveniences, the edges in the opening being beveled off which allows the wrench to engage with apparent ease onto the nut. Generally speaking most operations that have to be repeated over and over again in the course of one's work can be similarly improved upon.



TIME SAVING IN MACHINE SHOP PRACTICE.

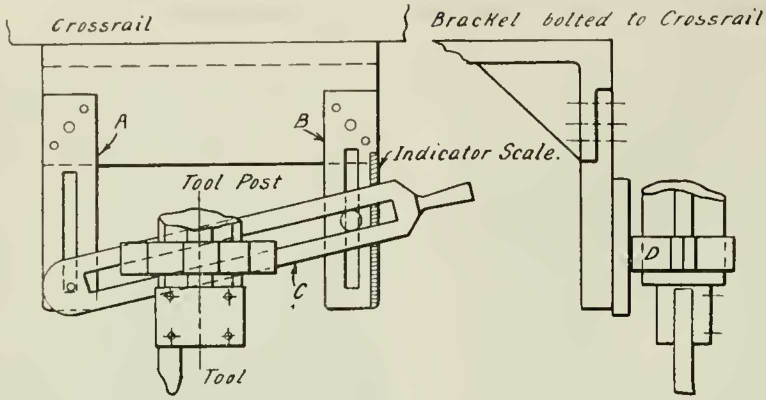
TAPER TURNING ATTACHMENT TO BORING MILL

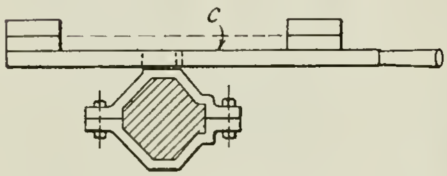
By E. T. S.

THE diagram shows a simple arrangement for producing duplicate taper faces on a boring mill. It consists of a master guide which is adjusted to the taper required. A pin in the tool bar fits into the slot in the master guide, and the horizontal feed of the cross rail is set in motion.

The vertical feed is released so that the position of the tool follows the shape of the master guide. It can readily be seen that any special form of surface can be made by providing the proper shaped master guide.

Slotted brackets A and B are bolted to angle brackets which is attached to under side of cross rail. The guide C is adjustable to any position or angle, the angle being shown by the indicator scale. Collar D is fitted to tool post and has a guide block that works in the guide C. In operation the cross feed is set, and the vertical feed left loose.





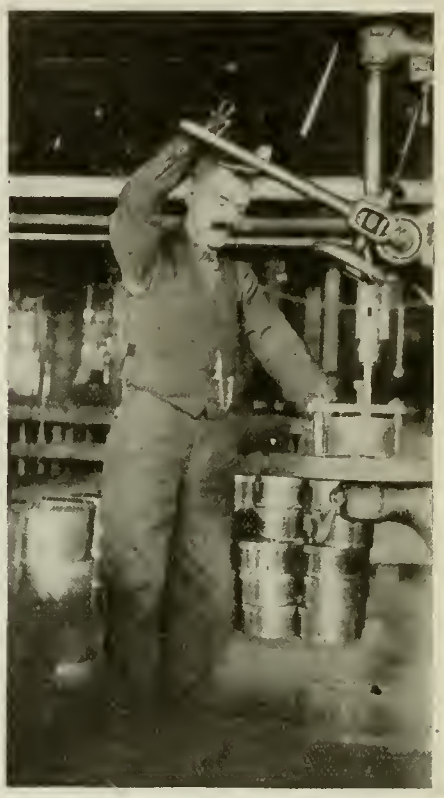
TAPER TURNING ATTACHMENT FOR PISTON RODS, ETC., AS FITTED TO 60" NILES BORING MILL.

STEEL HANDS FOR MACHINISTS.

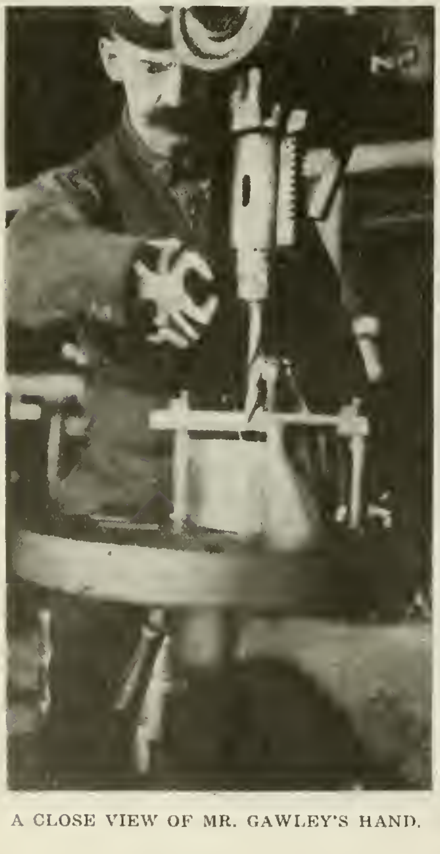
UNTIL recently, the loss of both hands has been looked upon as a calamity little short of total disablement, which, if alleviated at all by the use of artificial limbs, was still sufficient of a handicap to prevent the victim from earning a livelihood at any light employment, let alone performing operations of a fairly arduous nature in machine shop work.

Such, however, is not the case with the man who is shown in action in the illustrations herewith.

Andrew Gawley was formerly a resident of Meaford, Ont., and suffered the loss of both hands above the wrists many years ago through coming in contact with a circular saw. During his stay in hospital his mind naturally dwelt on the disaster and its probable effect on his future existence, with the result that he conceived the germ of the idea which has done so much to ameliorate his lot. On his recovery. he was persuaded to accept artificial hands of existing type, which, however meritorious in themselves, were of little use to a man who did not retain one natural hand. Accordingly, with the aid of his brother and a blacksmith acquaintance, Mr. Gawley had a pair of hands made embodying his own ideas. Extended experience suggested various improvements, until to-day he can do with his steel hands almost anything that an ordinary man can do.



ANDREW GAWLEY DRILLING ADAPTERS IN A VERTICAL DRILLING MACHINE.



A CLOSE VIEW OF MR. GAWLEY'S HAND.

LIFTING A HEAVY FORGING WITH ONE HAND WHERE GRIPPING SURFACE IS LIMITED.

Performing Machinist's Work

He is now employed by the Fisher Motor Co., Orillia, Ont., and officials of the company vouch for the fact that on any work on which he has been tried, Mr. Gawley possesses efficiency equal to any man in the shop. In drilling shell adaptors, as shown, he can lift them on and off the machine with one hand, which is more than the hand of flesh and blood can do, due to the small surface available for gripping the piece. Operating the drill press feed lever, tightening nuts with wrenches, turning handwheels, and throwing belts up and down cone pulleys, were constant features of his daily work. As tool room attendant, he has to handle tools and pieces of all shapes and keep written records of all articles in use.

Regarding his ability to perform work of a personal and domestic nature, it is stated that he can, when necessary, search for a match and light a lamp, dress himself and procure his own breakfast. His handshake can be very unpleasant on occasion, while he can handle china and similar fragile goods as tenderly as a woman.

Considerable interest is being displayed in his apparatus in view of the number of maimed soldiers now returning to civilian life. Many of these were formerly machinists, and their previous skill, combined with that adaptability which is so frequently the outcome of affliction and handicap, should enable them to use such a device as Andrew Gawley's hands, so that they may to a greater or less extent be able to resume their former employment with little if any lack of efficiency.

SCREW THREAD MEASUREMENT*

AT the beginning of the war, when British manufacturers were compelled to make parts in large quantities which should be interchangeable, several facts became evident, particularly in relation to screw threads. The following were some of the principal needs:—

1.—An exact definition of standards and manufacturing limits to meet the new and abnormal condition.

2.—A more widely diffused knowledge of the principles of gauging and gauging limits.

3.—Experience in the method of producing accurate gauges.

4.—Knowledge of the methods of accurately measuring and checking gauges. The definitions adopted throughout the article are illustrated in Fig. 1.

While no one instrument has been devised for measuring all the elements of a screw thread in the best possible way, the microscope micrometer has proved the most useful for all round service.

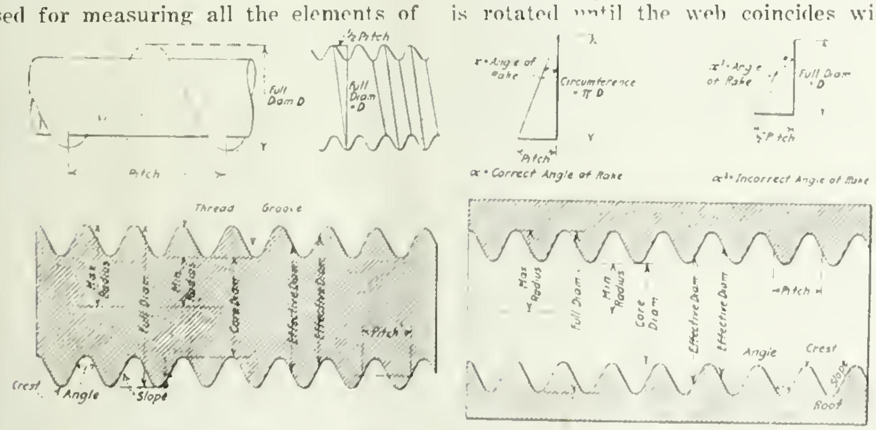


FIG. 1. SKETCHES SHOWING DEFINITIONS ADOPTED FOR VARIOUS PORTIONS OF SCREW THREADS.

*From a paper read recently before the Liverpool Engineering Society.

The instrument consists of a microscope which can be rotated about its axis, a degree of rotation being measured by a circular scale divided into half degrees and provided with a vernier. A single thread of spider's web is stretched across the eye piece and can be rotated with the microscope. The screw under observation is mounted on centers and can be moved in two directions, first along the axis of the screw and second in a direction at right angles to the first, both movements taking place in a plane normal to the axis of the miscroscope. The movements are controlled and measured by means of micrometer screws rading to 0.0001 in.

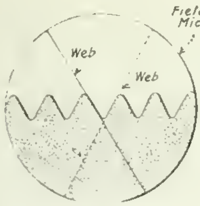

FIG. 2. METHOD OF MEASURING THREAD ANGLE BY MICROSCOPE MICROMETER.

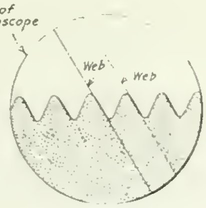

FIG. 3. METHOD OF MEASURING PITCH BY MICROSCOPE MICROMETER.

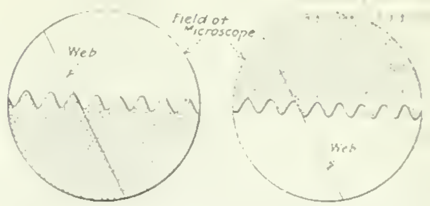

FIG. 4. METHOD OF MEASURING EFFECTIVE DIAMETER BY MICROSCOPE MICROMETER.

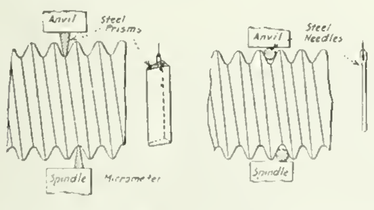

FIG. 5. METHOD OF MEASURING THE CORE DIAMETER AND EFFECTIVE DIAMETER BY MEANS OF A FLOATING MICROMETER.

The screw is illuminated by a beam of approximately parallel light rays shining over the crests of the threads from the side of the screw remote from the microscope, and up the microscope tube. The direction of these rays must be in the rake plane of the thread. The accompanying illustrations show the method of using the microscope to measure the various parts of the screw. Fig. 2 illustrates the method of measuring the angle of the screw. The tube is rotated until the web coincides with the edge of the profile of the screw and the angle of the web is read from the circular scale. It is then rotated as shown until the web coincides with the edge of the adjoining thread. The difference between the reading in the first and second positions of the web gives the angle between the threads.

Fig. 3 shows the method of measuring the pitch. The web is brought in coincidence with the edge of the screw as for measuring the angle, and the screw in then moved in an axial direction by means of the micrometer until the web coincides with the corresponding edge of the next thread. The diflerence between the micrometer readings gives the pitch. Similarily, the effective diameter is measured as shown in Fig. 4. The web is brought in coincidence with a thread as before, and the screw in then moved transversely across the field of the microscope until the lower edge of the same thread corresponds with the web. Lateral movement is given the screw as necessary by means of the other micrometer. The difference in the readings of the first micrometer gives the effective diameter. It is quite evident that the other elements of the screw can be measured by similar means.

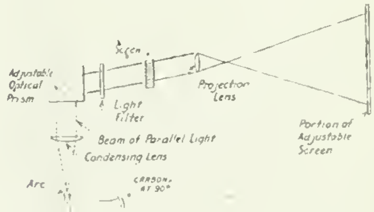

FIG. 6. PRINCIPLE OF THE OPTICAL PROJECTION APPARATUS.

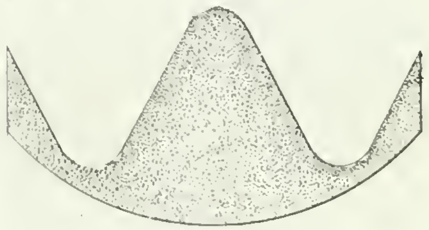

FIG. 7. COMARISON OF THE PROJECTED IMAGE AND TRUE SCREW THREAD OUTLINE.

The apparatus, as is the case with all optical instruments, is not entirely free from the personal error in observing. On the other hand, those measurements which involve similar settings of the web to produce consecutive readings are largely free from the personal error, since, being repeated, it disappears in the subtraction for the result. A careful observer with a little practice can get results true to 0.0001 in. or ¼ deg. of angle or less.

Another method of checking core and effective diameters is by employment of a micrometer floating on balls. The screw to be measured should be of good thread profile with an approximately correct angle. The micrometer is free to traverse the entire length of the screw , but also maintains its position at right angles to the axis. To measure core diameter, two pieces of hardened steel in the form of triangle prisms are employed as in Fig. 5. The cross-section of the prisms is an isosceles triangle with the apex slightly rounded and the apex angle about 10 deg. less than that of the thread to be measured. The prisms are suspended in the angle of the thread, as shown, and the measurement gives the diameter of the core plus the altitude of the prisms. This altitude is determined by separate micrometer measurements, and the difference between the two gives the core diameter.

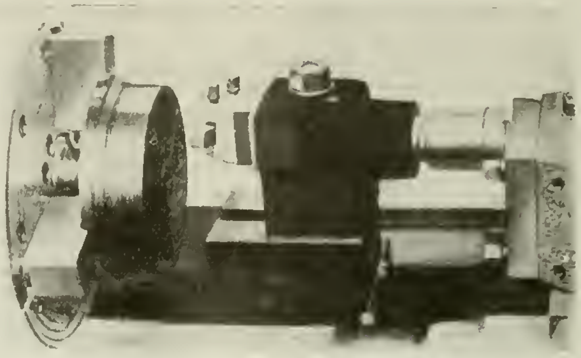
The method of determining effective diameter is also shown in Fig. 5, where cylinders, lapped circular and parallel throughout their length, are substituted for the prisms. Two of these needles of the same diameter are required for each different pitch of thread. The diameter should be such that the needles touch the slope (considered in an axial plane) of a theoretical correct thread in the middle. The micrometer reading gives the diameter over the outside of the two needles from which the effective diameter can be determined by the National Physical Laboratory formula.

$E = T + 0.96049P - 3.16568C - 0.086P^2C \div E^2$, where E is the effective diameter, T the micrometer reading less the sum of both needle diameters, C the mean diameter of needles and P the pitch.

Fig. 6 represents the principle of the projection apparatus whereby a largely magnified shadow of the thread profile is thrown on a paper screen at a known magnification. The best results are given by working with a magnification of about 50 at the screen. An outline of one or two threads of the form and pitch of the screw under examination is exactly drawn in a fine black line on the screen at the required degree of magnification and the image is projected to coincide with this line. The projection apparatus has a large application in precision work other than screw threads. Gear teeth can be examined and the outline of contour gages, cams, etc., compared with the perfect shape. Fig. 7 shows a comparison of the projected image and the true thread outline of a Whitworth thread as given by an optical projection apparatus.

SIMPLE TAPER TURNING ATTACHMENT

THE illustration shows a simple type of taper turning attachment, supplied by Alfred Herbert, Ltd., Coventry, England, for use on their No. 4 Capstan lathes, and which is intended for machining tapers up to about 1½ inches long on valve seats, plugs and similar work. The attachment, which will take care of a large variation in taper, consists of a casting bolted on to the back of the cross slide by a single bolt round which it can swivel. The casting is bored to receive a sliding bar, at one end of which is formed a cutter head carrying the tool. The sliding bar is keyed to the casting, and a spring is provided which keeps it normally away from the headstock. On to one of the turret faces is bolted a cast iron plate with a projection arranged to push along the sliding bar when the automatic feed to the turret is engaged. The cutting tool, therefore travels in a path, the inclination of which can be altered by swivelling the tool holder, whilst the cut is put on from the cross slide in the usual manner. The cutter head is cranked so that the point of the tool is on the centre of the sliding bar, and the turning moment set up by the cut is therefore small, and does not tend to put excessive friction on the sliding key.



SIMPLE TAPER TURNING ATTACHMENT.

SAVING STEEL IN SHIPBUILDING

IT is interesting in connection with the United States big shipbuilding push to learn that in mercantile shipbuilding, before she declared war, no fewer than 140 ships were ordered on the Isherwood system of construction. They represent a deadweight carrying capacity of 1,344,000, and it is estimated that the saving in steel by adopting this system is 40,000 tons.

Within the last few weeks, J. W. Isherwood, the patentee of the system, has received further requests to proceed to the States in connection with the construction of standard ships; and Japan, which is taking up the same idea, will afterwards be visited by Mr. Isherwood at the request of shipbuilders in that country. It is noteworthy that 700 ships have been built, or are under construction, on this system despite the fact it was only introduced a little over eight years ago, and it claims, we believe, 95 per cent. of the oil tank vessels now being built throughout the world. Mr. Isherwood, who is comparatively a young man, was formerly a member of the technical staff of Lloyd's.

Of considerable importance is the fact that out of a total of 672 ships which have been built on the Isherwood system, and which represent a total deadweight carrying capacity of 5,200,000 tons, the enormous amount of 150,000 tons of steel has been saved, as against what would have been required for the construction of the ships in the ordinary way. It is estimated by a well-known naval architect that if the Government should give out contracts for 200 ships, by adopting the Isherwood system 34,000 tons of steel could be saved.

SHIP PLATE MANUFACTURE IN CANADA

CANADA will not be in a position to build steel ships in quantity for at least two or three years, according to a statement by Mark Workman, president of the Dominion Steel Corporation, on May 10. He added that scarcity of steel was the chief cause. Mr. Workman stated that the entire output of steel from the Dominion Steel Corporation plant had been contracted for by the Munitions Board up to the middle of 1918, and the chances now were that this contract would run into 1919.

Some criticism has been directed at the officials of the corporation because of the sale of a ship plate mill some months ago to American interests. Mr. Workman, when asked regarding this, explained that the plant sold was incomplete, and that it would be impossible to make ship plates from it. He pointed out that he thought it had been purchased some seventeen years ago, had never been operated nor installed. He added that a plant properly equipped to manufacture ship plates would require an expenditure of something like $2,500,000 and the plant sold had been purchased for $70,000.

Going further into the prospects of steel shipbuilding in Canada, Mr. Workman said that it would be an absolute impossibility for the Steel Corporation to operate a plate mill at the present time, even if they had one on the ground, because of their inability to secure raw materials. The corporation has a rail mill lying idle because sufficient ore cannot be obtained to operate it.

"The Canadian Government Railways, the Canadian Pacific and the Grand Trunk Railways are all crying bitterly for rails, but we can do nothing to help them as shell requirements just about exhaust our product," he said. To increase the steel output further, Mr. Workman explained they would have to start at the ore output from the mines. Additional furnaces would have to be installed, as well as new coke ovens. Work is at present well advanced on these extensions, and the corporation is spending this year something like $5,000,000 in extensions and improvements at Sydney, but this increased output is all provided for in contracts already made with the Munitions Board.

"These extensions will require a great deal of additional labor and it will be another question whether we can secure this or not," he concluded.

USE OF GLUE IN STEEL POLISHING INDUSTRY

By H. O. Anderson.

THERE are a great many varieties of glue upon the market, but the glue used in the polishing trade is a product of the action of heat and water on nitrogenous animal tissues. This is known as animal glue and more often simply as ground glue. Glue is made from the by-products of the packing houses by boiling the animal tissues with water. From the fact that there are so many materials from which glue is made and for the fact that it is only a water solution, various lots of the same kind of glue can very considerably. Too much care, therefore, cannot be exercised in becoming familiar with each shipment before putting it into actual use.

There are many reasons why two lots of glue from the same dealer and of the same kind might vary considerably as made, but aside from these, from the time a lot of glue has been received into the polishing room to the time it has been incorporated with the abrasive upon the polishing wheels, there are fully as many causes for variations. The use of glue in a polishing room is, therefore, a most important operations, not only from the point of economy but also for good results, and elimination of complaints on abrasive grain and on glue.

Some may think that to prepare a solution of glue, all that is required is to throw a small amount of the ground glue in with any portion of water, heat up to boiling and the glue is ready for use. Glue prepared in this manner would cause complaints against the glue dealer on the very first day of its use, or, on the other hand, the dealer of the abrasive grain would receive a complaint that the glue does not hold the abrasive to the wheel.

If glue is received in the sheet form, it is always well to pulverize it. Ground glue absorbs water and melts in the heating so much sooner that the time spent pulverizing is well paid for. The amount of water to be added to any portion of glue should be determined in the cold water soak, and this is very important, because the water absorption, the tenacity of the belly and the viscosity of the solution are very important factors in obtaining the best holding power with the least amount of glue. If the flake or sheet glue is not powdered, it requires a longer soak. The same consistency of a glue solution cannot be expected to work properly with coarse abrasive grain and with the finer sizes. The finer the abrasive grain the thinner should be the glue solution.

It is a well known fact that the weight of ground glue varies considerably, which is a very good reason why the glue and water to be mixed should be carefully weighed. Some glue mixers fail to weigh these materials, believing that by measuring the glue and water the same consistency can be obtained which, of course, is not true. It is very important that the proportion or weight of glue and water be correct in the cold soak, because, after heating, if the solution is found too thin and more glue is added, or, if on the other hand, the solution is thick and more hot water added, very unfavorable results must be expected.

Soaking and Heating

The best time to make the cold water soak is at night, then allow to stand in a fairly cool place until morning, when it is ready for the heating process. Care must be taken that this solution does not freeze during the night soaking. The glue pot should be thoroughly cleaned out in the evening, scoured if possible, so that no dried or over-heated glue remains in it to contaminate the fresh solution. This pot should be made of copper, brass or aluminum. Under no circumstances should iron glue pots be used, as these corrode considerably, due to the action of the water, and the acid in the glue, so that in the long run the iron pot, although cheaper at first cost, will be the most expensive.

The most expensive glues can very easily be so spoiled that they would not be as satisfactory as the very cheapest glue upon the market. The greatest care in glue preparation should be during the heating operation. Never allow direct heat to come in contact with the glue pot, either as a coal fire or live steam. The proper way of heating a glue solution when glue converters are not in use is to have the glue pot surrounded by a water jacket, then either heating the water with live steam or an electric coil. If an automatic temperature controller is not used, a thermometer is recommended in the glue solution and under no circumstances should the temperature exceed 160 degs. Fah. The heating should be conducted so that the glue solution averages from 150 degs. to 160 degs. Fah., for 1½ to 2 hours, after which it can be cooled down to 130 degs. to 140 degs., and allowed to remain in this condition while being used.

If it is not necessary to continue the heating of the glue all day, a better method is to make up only such amount as is to be used immediately. Under no circumstances should more glue be made up than can be used in one day. A glue that has been allowed to stand for 10 hours, then cooled over night and reheated in the morning is absolutely of no value. If a glue is allowed to heat at the higher temperature, that is from 160 degs. to 170 degs. Fah., the value of this glue is reduced about one-third to one-half cent per pound per hour. Therefore, if conditions are such that the glue must be kept warm during the entire day is should not be at the upper temperatures. Then, too, glue is one form of gelatine and gelatine is the medium in which germs are multiplied very rapidly. Deterioration of glue for this reason will result from prolonged heating. Where the glue dissolvers are at hand it is always recommended that these be used so that fresh solutions of glues can be quickly made up.

Another factor which enters into the preparation of glue in open glue pots is the evaporation of water. If a great deal of the water has evaporated so that the glue solution has become thicker, after several hours of heating, it is a very simple matter and a custom in some polishing rooms to add water. This is detrimental to the entire solution and it is also very unsatisfactory to use the thickened solution. Therefore all glue pots should be covered.

After the glue has been applied to the polishing wheels, which should have been heated before the application, the coating of abrasive, which has also been heated, is to be applied. If a warm solution of glue is applied to a cold polishing wheel, the chilling effect of this wheel will cause the glue to partially set or harden and thereby not hold the abrasive. If, on the other hand, the abrasive is in the cold state, this will also have a chilling effect upon the glue, and before a proper combination between the two is effected, the glue is so partly hardened that the abrasive will very easily fall off in the polishing operation.

After the wheels have received the applications of glue and abrasive, they should be dried for at least ten hours before using. This drying must not necessarily be conducted in a very hot room but, if fairly warm, they can be allowed to lay around in the polishing room. The temperature and humidity of a polishing room will change the action of the polishing wheels considerably, therefore the condition of the atmosphere in the polishing room should be kept as constant as possible so that like polishing conditions can always be expected.

The most important things in a polishing room are cleanliness of the glue pot, accurate weight of glue and water in a mixture and exceedingly careful consideration in the heating of the glue solution.

Do not expect to get good results from a glue which has been mixed in any proportion with water heated up rapidly to very high temperature, or by using a glue which was used a day or two before.

Do not expect to use glues that have been heated with water less than one to two hours unless glue converters and dissolvers are in use.—Grits and Grinds.

Comparative Mechanisms—

The Master—You look worried. What's the matter?

The Housekeeper—The nurse has just left, and there is nobody to wash the baby.

Master—Have the chauffeur do it. There isn't as much mechanism about a baby as there is about a car anyway.

NOTES ON NON-FERROUS METALS FOR ORDNANCE WORK

By G. C. R.

MUCH has been said about the machines, presses, tools and methods used for producing cartridge cases and copper bands for shells, but little has been said about the metallurgical methods when the trouble experienced in obtaining an adequate supply is considered.

The physical properties govern the methods of manufacture, and in the case of the copper bands the requirements make the difference between cast or rolled material. In the larger sizes of bands these specifications are all the more important, particularly when the lands of the rifling of the gun become worn, and form a small bearing area which, when inferior material is used, tears and rips.

Formerly the French artillery specifications not only specified the analysis of cartridge brass, but the brands of copper and spelter which would be accepted were also named. This was caused to try and prevent the use of spelter containing lead, iron and cadmium. These undesirable elements have various effects, such as reducing the ductility, etc. Cadmium and its effect in small proportions has been investigated very little, but apparently the melting point of brass is so high that the cadmium volatilizes and the remaining percentage has little effect due to the difference in the melting points which seems to be the principal trouble.

Small Bands Cast

In the case of the smaller sizes of copper bands, the specifications can be met with cast copper, while the larger sizes must be subjected to rolling or other treatment. The smaller bands are top poured and cast in steel tubes with hay loam cores. The hay is not twisted into a rope, but is picked out from the bin and laid in place covered with loam.

The cylinders are turned on the outside and cut to lengths, after which the bands are chucked and a cleaning cut made on the inside. The larger sizes must be rolled or worked, and in some cases the method of procedure is to cut out the blanks, which are about 36 in. dia. cup and draw similar to cartridge case work, care being taken to anneal between operations at 1,500 degs. F. A noticeable feature in the drawing operation is the amount of play on the cross-head or ram supporting the punch. Lubrication is used, as in brass drawing.

Melting the Copper

The copper for these purposes is produced in an oil furnace, pure scrap, as near as possible to obtain, being used, including cuttings. The refining is done by covering the surface of molten copper with charcoal and by rabbling or puddling with a green pine pole, possibly 5 inches in dia. and 15 ft. long. This poling causes steam and gases to form from the green wood, reducing the oxides and impurities. The slag which forms on the surface, and which contains the impurities, is taken off and test buttons are taken to see if the process has been carried far enough. These buttons are about 1⅛ in. in diameter. The condition is judged by fracture, which should be pink, and not red, and by the shrinkage or lack of it. The latter is termed pitch, which means the shape of the top of sample, i.e., convex, straight or concave. What is required is a slightly concave surface, and if it is not as desired, poling must be continued, and if too concave, oxygen must be added and the process repeated, but this requires considerable mechanical skill to restore this overpoled copper.

The slag obtained from the refining contains good metal, and should be remelted in a cupola with suitable fluxes and the reclaimed copper subsequently refined.

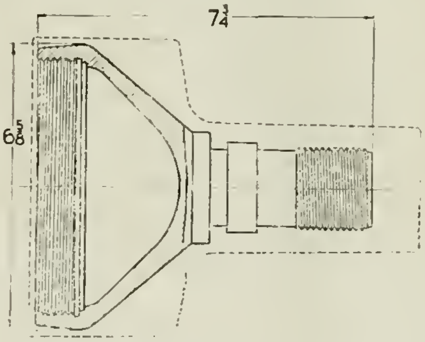

FIG. 1.

The medium-sized bands are made from castings about 9½ in. dia. x 9½ in. long, which are cast in metal molds on a rotary platform, after which they are annealed at 1,500 degs. F. for half an hour, and the cupping and drawing operations which are performed on horizontal hydraulic presses follow.

The brass for cartridge cases is composed of from 15 per cent. to 40 per cent. scrap, depending on the available supply, but no fine cuttings or dross are included. Melting is done in crucibles heated by coal in open pit types of furnace.

Pouring Billets

The molds, which are cast iron, hinged at bottom, with clamps at top, which are part of the pouring basin, make a billet about 1¾ x 9 x 30 in. Pouring is from the top through gates about ⅝ in. dia., and the temperature and process is watched so carefully that there is very little discard, if any. The billets are now taken to a high-speed machine, which cleans off all dirt or dross which may have gathered on the sides during the casting operation.

The rolling operation consists of eight passes, with a reduction of ⅛ in. per pass. After passing the first three passes a lubricant is applied.

In blanking the finished sheets a shear is used behind the punch and die; in this

FIG. 2.

manner the trimming permitted handling for further blanking, and the scrap was automatically cut to correct size for subsequent remelting.

MACHINING RECUPERATOR DETAILS FOR FIELD GUNS

Herbert's Monthly.

THE efficiency of the modern field gun is measured, not only by the number of rounds which can be fired per minute, but also by the steadiness of the gun, which enables it to keep on the target, thus reducing the time required for re-sighting. The field guns of 25 years ago had no means of absorbing the recoil, and had to be re-sighted after each shot. Designers of artillery have therefore paid a considerable amount of attention to the buffer and recuperator, which absorb the recoil of the barrel, and bring it back to the firing position; the latest designs being remarkably efficient. Many of the details are very suitable for production on combination turret lathes,

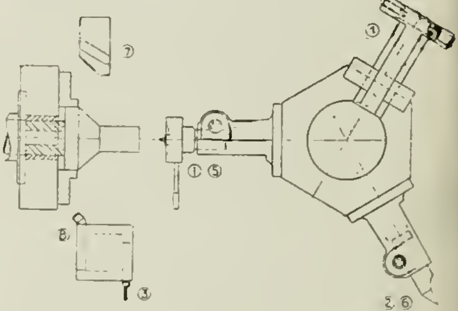

FIG. 3.

and capstan lathes, and one of these of more than usual interest is the adapter for breach lug shown in Figs. 1 and 2. The material from which it is made is a steel forging of about 40 tons tensile strength, which is shown circumscribing the finished work in Fig. 1. It will be noted that there is rather a large amount of metal to be removed, especially from the taper portion and from the end of the shank. The lathe operations are handled on Herbert No. 9 combination turret lathes, and are three in number.

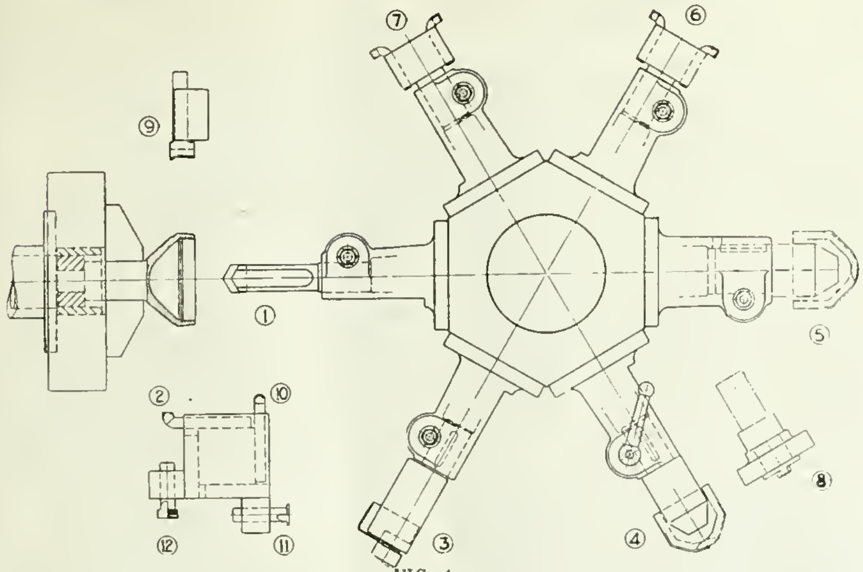

FIG. 4.

The first operation, which is something in the nature of a preliminary roughing operation, is shown in Fig. 3. The shank is rough turned to provide a good grip for the chuck jaws used at the second operation; the superfluous metal is removed from the shank end, and the taper rough formed. At this operation, the forging is held by the large diameter in standard jaws of a 15-in. Coventry chuck, being set back against a standard steady bush and liner in the bore of the chuck. The tools, which are numbered in the illustration in the same sequence as used, are as follows:—

1.—A roller steady centering tool for centering the end of the forging. As the forging is in the rough state, the roller carriers are not required, and are removed from the centering tool. The lever feed to the centering tool is very useful on the larger turret lathes, as it prevents breakages to the drills.

2.—A dead centre for supporting the end of the work while tool 3 is cutting off.

3.—A cut-off tool which removes the superfluous metal from the forging, and steps down to start the boxtool.

4.—A patent inverted roller steady boxtool, which turns the shank.

5.—The centering tool is used again for re-centering the shank.

6.—The dead centre is used again for supporting while forming the taper.

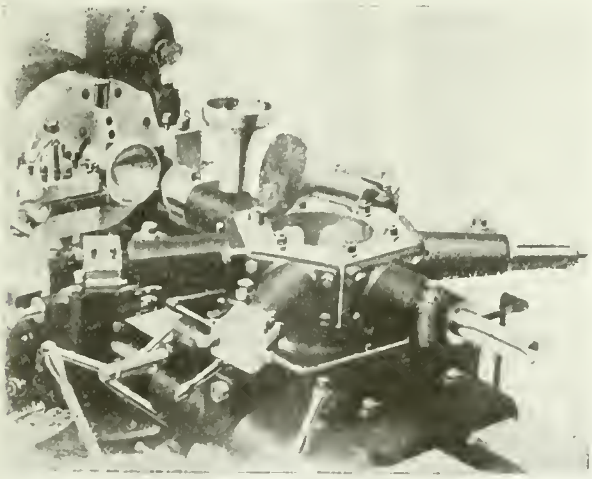

FIG. 5.

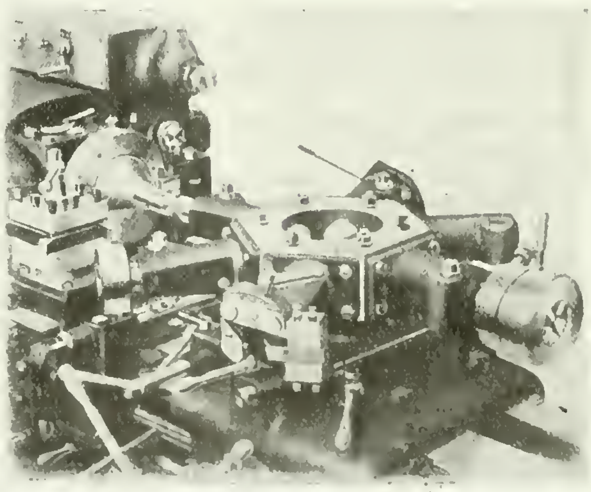

FIG. 7.

7.—A taper form tool carried in a special tool holder on the back of the cross slide, for roughing out the taper.

8.—A facing tool for the end of the shank, which removes the centre hole.

The time for this operations is 15 minutes.

At the second operation, which is shown in Fig. 4, the work is gripped by the shank rough turned at the previous operation, with special jaws in the Coventry chuck. The jaws are made longer than usual, so as to get the strongest possible grip, as the work of this operation is heavy. The sequence of operation is as follows:—

1.—A patent straight flute drill with inserted spiral cutter for drilling a pilot hole for counterbore 3.

2.—A rough turning and facing tool, which operates simultaneously with 1.

3.—One of our standard type counterbores, which opens out the hole as deep as possible.

4.—A rough spade tool for form boring.

5.—A finish spade tool.

6.—A rough boring bar for the thread diameter and the plain diameter beyond.

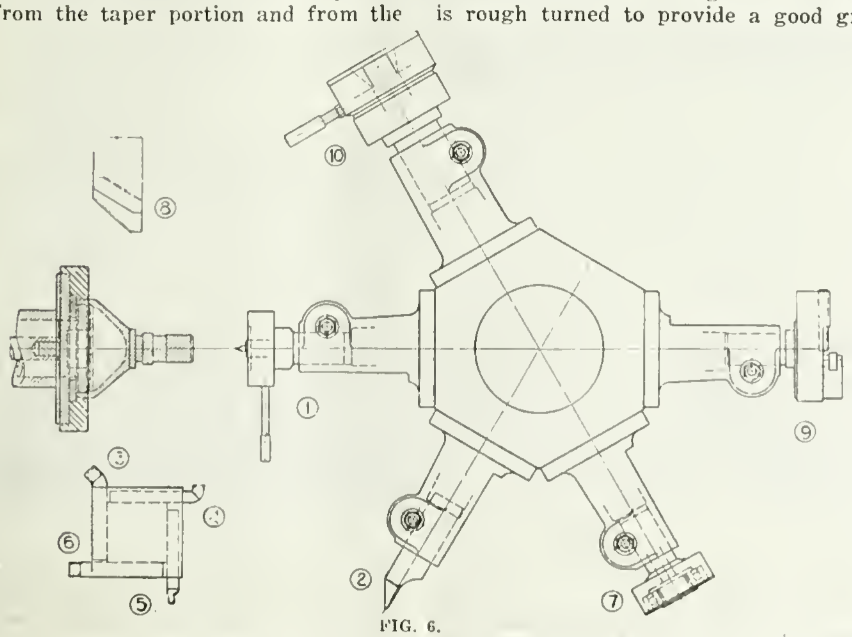

FIG. 6.

7.—A finish boring bar for the same diameters.

8.—A revolving steady bush interchanged with 4, for supporting during the forming operation 9. The interchanging is simplified by fitting a clamping handle to the pad bolt in place of the usual hexagon nut.

9.—A form tool for the external taper, carried in the standard back toolpost.

10.—A small form tool used for finish facing the end, forming the small external ridius, and chamfering the mouth of the hole.

11.—An internal recessing tool for the back of the thread.

12.—An internal chaser. The machine set up for this operation is shown in Fig. 5, the machining time being 50 minutes.

At the last operation, as shown in Fig. 6, the work is held on a screwed drawback arbor peg, and the sequence of the tooling operations is as follows:—

1.—A centering tool for re-centering the end of the shank.

2.—A dead centre for supporting.

3.—A turning tool which turns the thread diameter, and the intermediate collar.

4.—A finish turning tool for turning the large diameter.

5.—A form tool for the narrow groove, and for producing the small diameter at the end of the thread.

6.—A form tool for the wide groove.

7.—A ball-bearing steady bush holder, which supports on the thread diameter, whilst forming with tool 8. For accurate forming it provides a better support than the dead centre.

8.—A taper form tool carried in the same tool post as used at the first operation.

9.—A roller steady and rounding tool.

10.—A Coventry patent self-opening diehead. The time for this operation is 25 minutes, and the machine is shown in Fig. 7.

FABRIC BRAKE AND CLUTCH LININGS

By L. E.

THE extent to which fabric has replaced all other substances as a friction material for brake and clutch linings is hardly realized even by engineers. Practically every automobile, for example, now has fabric lining on its clutches and brakes, whilst all the underground railways in London and Paris, as also in the Glasgow subway, now use fabric brake-linings in place of metal blocks. Mr. J. Oswald, of Glasgow, stated that cotton brake-blocks were first tried on horse-cars and were found to have points of very great superiority over wood, especially as regards their efficiency when heated by friction.

Since that time great improvements have been made in the manufacture of friction fabrics. The bonding cement has been rendered more heat proof, and a process has been developed whereby the burning point of the fabric itself is raised 75 per cent.

Fabric lining is of two main kinds—that made of cotton, and that made of asbestos. According to Mr. Oswald, the cotton fabric has the highest co-efficient of friction, i.e., 0.5 to 0.7, and is capable of absorbing much greater work in foot-pounds per sq. in at a given pressure than asbestos material. The co-efficient of friction rises with increased temperature, and is practically unaffected by oil or water. In actual test results obtained by the National Physical Loboratory on cotton material, the work absorbed in foot-pounds per sq. in. per minute was 72,000 dry and 70,000 when lubricated, the pressure being 39 lbs. dry and 160 lbs. lubricated.

The choice between cotton and asbestos is determined in part by the amount of heat that is likely to be generated. The heat limit with cotton is 400 deg. F., and in all cases where this heat limit is likely to be exceeded it is advisable to adopt asbestos material. The co-efficient of friction of this material is 0.3, and it is remarkable that it practically remains constant under varying conditions. Its value lies in its great heat resisting qualities, which recommend its use on exceptionally heavy and prolonged braking or similar duties. Owing to its nature, asbestos material is usually reinforced with brass wire, which makes it more expensive than cotton. Failures with fabric linings are not unknown, but the majority of them Mr. Oswald ascribes to preventable causes: (2) The use of wrong material; (b) to failing to keep the fabric face clear of the opposing face when the brakes are out of action; (c) failing to ensure that the fabric is kept well home when applied, or, in other words, "followed up"; (d) incorrect fixing of linings to the engaging media; also (e) through expecting too much from brakes which have been under-dimensioned by the makers for the duties they have to perform.

Collieries, it appears, are now taking up fabric linings extensively for brakes on main winding engines and haulage gears. Their use saves the rope considerably on account of the smoother action, the upkeep cost is even less than with wood, and there are further advantages in the shape of improved control and speedier working.

The immediate reason for introducing fabric linings for the brakes of the underground railways is interesting. Iron brake blocks give off an amount of iron dust which totals to surprising figures. Three-quarters of a ton of brake-dust per mile has been proved to be produced every month in the New York subway. This dust not only short-circuits the electrical signalling apparatus, and causes stoppage of trains daily, but as it settles on the track the oil from the motors becomes mixed with it and forms a highly inflammable mixture. It was the accumulation of this and the red-hot sparks from the metal blocks which caused the Paris fire a few years ago, in which 480 people lost their lives. Fires in London underground railways have also been attributed to this cause. The rapid running of the trains throws off oil from the motors under the coaches and the atmosphere being charged with metal dust, a very inflammable mixture is scattered all over the train.

It was partly to prevent these troubles that the cast-iron blocks were abandoned in favor of cotton linings. Since their introduction not a single fire has been reported on any of these railways. Continued use led to the discovery that there was no appreciable wear on the tyres and rails, these being highly burnished. A further very important result is that since fabric linings have been used, rail corrugation and flats on wheels, which commonly existed with the use of metal brake blocks, have disappeared.

THE EFFECT OF STORAGE ON COAL

By S. D.

IT IS a matter of obvious and common knowledge that if stored coal be allowed to generate spontaneous heat its calorific value will suffer heavily, and for that reason storage under water has been from time to time advocated and practised; but there is also a widespread assumption that apart from spontaneous heating coal stored in the open deteriorates sensibly in the course of a year or two as a result of disintegration accompanied by chemical loss. Tests carried out over the last five years point to the entire fallaciousness of that belief, so far at any rate as the gas-making properties of coal are concerned.

A truck load of each of two grades of gas coal were set aside five years ago for the purpose of the experiment. The coal was stored in the open, in bins nine feet deep, provided with separate compartments, and each succeeding year a compartment was cleared and the coal tested in 400 lb. retorts. The results fluctuated somewhat from year to year, but after allowing for certain variables in the working of the retorts, the conclusion was arrived at that no deterioration in the gas-making quality of the coal had taken place even at the end of the fifth year.

The main body of the coal suffered little physical change during the five years. The top six inches had crumbled considerably but even in this top six inches chemical analysis failed to reveal any material change, even after five years' weathering.

It may be taken, therefore, that gas coals can be kept for five years exposed to fairly severe climatic conditions and be none the worse for it, provided there is no internal heating of the mass. It may be pointed out, however, that the conclusion would not necessarily hold good in the case of steam coal, as the crumbling of the upper layer would yield a certain amount of fine coal which under average steam boiler conditions would be apt to be drawn over the top of the fire and so pass unburned into the flues.

Standardization Applied to Cargo Boat Machinery*

By D. B. Morison

The industrial problems of the future must be faced, and faced quickly — moreover, they must be solved, and solved quickly. The onus of responsibility falls primarily on capital, in the provision of standardized organization, direction ,and equipment, whereby the best is accurately determined and the best is progressively maintained; thereafter capital and labor must co-operate in standardizing rapid production, so that good general trade may be promoted by steady employment at high wages to the lasting benefit of the industries concerned and the general welfare of each individual community, and the nation as a whole.

ALTHOUGH it is imperative that maximum effort, individual and collective, should be concentrated on winning the war, it will be well if our energies can be so directed that, without in any way prejudicing the main issue, they may be helpful towards a solution of the stupendous industrial problems ahead of us, and in avoiding the dangers of "too late." In engineering and shipbuilding the period of grace will be extended by reason of the general shortage of tonnage, but the deluge of world competition will be with us ultimately as sure as night follows day, and our success or failure will depend entirely on the use we make of the time and opportunity between now and then.

Capital and Labor

It is futile for capital to expect that labor will consent to any great reduction in wages. It will be equally hopeless for labor to expect the maintenance of the present high rate of wages without concessions on its part. Therefore, let both capital and labor seek whether by joint endeavor it will be possible to pay high wages in the future and yet maintain our trade. The requisites are, first, a candid acknowledgment by labor of the economic law that good general trade is dependent on maximum production, and, secondly, capital must recognize that maximum production entails correspondingly high pay. Capital and labor must realize that their interests are parallel, not divergent. Assuming that this fundamental principle is accepted, then the onus of organized preparation falls on the employer, as, unless unrestricted effort is well directed, its standard of useful efficiency will be so low that ultimate failure is inevitable. There can be no industrial success in this country of the degree demanded by the obligations of our national indebtedness without the full employment of labor at the highest standard of useful efficiency. Such a standard is only possible with the most perfect mechanical equipment and the most efficient general organization and management on the part of the employer, and with unrestricted effort and correspondingly high wages on the part of the employed. The manufacture in multiple of an arbitrary design is not standardization; it is merely repetition with the object of obtaining greater output. To standardize is:—

"Accurately to determine the best—progressively to maintain the best—and to produce of that best the greatest quantity by means of organized specialization in labor, in methods, and in machinery."

Progressiveness in Standardization

Progressiveness in standardization with regard to designs depends on how nearly reasonable finality has been reached. In the case of a pin or a pen, for example, improvement in design is barely possible. In a machine comprising an aggregation of parts, such as a self-binding reaper, the desired effect having been obtained, progress can only be associated with means for reducing the cost of manufacture or increasing the rate of work. The economic effect of obtaining the greatest possible power from steam by means of an engine is of such vast importance that the determining of the best, and the progressive maintenance of the best, are factors which also determine whether any given type shall continue to exist. Consequently the initiation of a standardized marine engine requires extraordinary care and ability in order that the standard shall be unsurpassable in efficiency both thermally and mechanically.

Propelling Machinery Standardization

A single mistake in determining the best in a standard engine prejudices for its entire life the commercial value of the ship that it drives, whether the mistake be reflected in steam inefficiency or mechanical inefficiency. It would seem, therefore, to be of paramount importance that the initial decisions should be vested in a body of marine engineers who are life specialists in the design, the manufacture, and the running of cargo boat machinery. In other words, the engine must start off as the leader of its type, it must maintain this lead, and the leadership must be generally acknowledged by cargo boat machinery experts. The incorporation in one design of the latest and best practice as affecting steam efficiency and running costs would

INTERIOR OF HULL UNDER CONSTRUCTION, AUXILIARY POWER SCHOONER "MARGARET HANEY."

*From a paper read at the spring meeting of the Institution of Naval Architects, March 28, 1917.

provide a measure, but the measure itself must be tested and adjusted by continuous research, both technical and practical, on organized lines, so that it is always "The Standard."

Determining the Standard

Failing a Government Engineering Bureau for the whole country, the engineering institutions would appear to be the best means to the desired end. An experiment in this direction has recently been made by the North-East Coast Institution of Engineers and Shipbuilders. The members and council have commenced on very conservative lines by preparing a guidance specification for triple-expansion engines for cargo boats, based on the best practice of the various specialized builders on the coast. It is proposed to begin on simple lines for this year, but an annual revision will be made in order that the specification may be gradually extended and kept thoroughly up to date, with a view to securing maximum rate of progress in technical advance, and commanding the confidence and promoting the ultimate interests of all concerned, viz., of the engine builder, the shipbuilders, and the shipowner. Other specifications on similar lines are to be prepared for quadruple engines, geared turbines and internal combustion engines.

Assuming that in the general problem of standardization this guidance specification of the North-East Coast Institution represents the best now obtainable, the next step is to provide means whereby there shall be progressive improvement by continuous investigation and research, supported by organized and collective practical experience. With regard to the latter, it is not sufficient that the engine builder gets rid of his goods on the day of the trial trip. There should be some system of co-operation between the engine builder and shipowner, whereby the general results in coal economy and costs for repairs over a prolonged period, certainly beyond the usual six months' guarantee, are recorded and rendered available. In order to secure the funds for carrying out this scheme, it has been suggested that the cargo boat engine builders of the North-East Coast should be invited to adopt the specifications at a small fee per horse-power. As the money so collected would be entirely devoted to promoting the progress of the associated industry, it is hoped and expected that there will be an enthusiastic response.

Auxiliary Machinery

In the matter of auxiliaries, the Research Committee appointed by the Council of the North-East Coast Institution will exhaustively test approved apparatus connected with a marine installation, and publish in their "Transactions" the results obtained. This will secure a reliable means of ascertaining the true performance of any apparatus so tested, and as the results will carry the hall-mark of the Institution for accuracy, the value of the scheme to the industry generally is obvious. In the matter of boilers and shafting, complete standardization of marine machinery is blocked, because the Board of Trade, Lloyd's Registry, and the British Corporation issue independent rules, which are based on physical facts as a constant and individual opinion as a variable. Just a very little co-operation and mutual sympathy would enable all the existing differences to be adjusted to the great advantage of the many industries involved.

When Lloyd's Registry revised their rules some years ago, they requested the assistance of a committee of experts selected by the leading marine engineering institutions. This committee has been very successful, as the various members, all of whom occupy leading positions in the several shipyards and engine works, are in such direct touch with practice that their experience establishes mutual confidence, to the great benefit of all concerned. A similar committee of experts was appointed by these institutions about the same time, with the object of providing a means whereby the many irritating disputes and misunderstandings, which so frequently arose some years ago between the Board of Trade and the manufacturers, could be overcome, the collective technical experience of the members being available in the event of new rules being issued or old rules revised. Each member of the committee was prominently associated with a shipbuilding yard or a marine engineering works, and all gave their services with enthusiasm, although often at great personal inconvenience.

In any progressive country on the face of this earth except our own, such a committee would have been welcomed, and its expert capacity officially recognized and utilized to the fullest extent for the common good; but the traditional antagonism to innovation, no matter how desirable, has prevailed. For twenty years this committee has given of its best to the cause of progress. It has never received adequate recognition or encouragement from the Department of State it was appointed to assist. It is gratifying to record, however, that a serious attempt is now being made to devise some mode of procedure for making full use of the existence of this committee in the national interests.

Assuming the various surveys decide to harmonize their rules so that standard design, scantlings, and physical properties of material may prevail throughout the range of cylindrical boilers as now supplied to cargo boats, the economic effect on the manufacture of the material and the building of the boilers would be very pronounced. It would at once be possible to prepare a series of standard designs, with accompanying specifications for plates, furnaces, tubes, stays, rivets, etc. The steel manufacturer could estimate the probable demand, produce in bulk, and give immediate delivery. The boiler builder would be freed from the delays arising from the preparation and submission of designs, and would simply order from the scheduled list—receive the goods exactly when required, and proceed with the manufacture with an economic continuity hitherto impossible. The following are examples of divergence between surveys:—veys:—

Divergence in Boiler Rules

1—For a single-ended boiler, 15 ft. 6 in. mean diameter, 11 ft. 6 in. long, 180 lb. working pressure, thickness of shell 1 3/32 in., tensile 28½ to 32½ tons per square inch, diameter of rivets 1 3/32 in., pitch of rivets 9½ in.

Working Pressure of Shell

		Pounds.
Board of Trade	=	183
Lloyd's Registry	=	210½
British Corporation	=	204½

2—For the working pressure for a suspension furnace, 3 ft. 10 in. inside diameter, ⅝ in. thick:—

		Pounds.
Board of Trade	=	185.3
Lloyd's Registry	=	200.5
British Corporation ...	=	196.5

An examination of the tables of pressure for these furnaces reveals to the curious that for thicknesses below 9/16 in., the Board of Trade allows a greater working pressure, the thinner the furnace, than Lloyd's, and for furnaces over 9/16 in. thick Lloyd's allow a greater working pressure, the thicker the furnace, than the Board of Trade. Arbitrary requirements also often involve unnecessary cost, as, for example, limitation by the Board of Trade of rivet pitch to 10½ in. with a tensile of rivets of from 27 to 32 tons necessitates an increase in shell tensile for large boilers, for which abnormal extras have to be paid to the steel makers.

A brilliant example of what can be achieved by well-directed collective efforts is the standardizing of stationary boilers in the United States of America by a committee of experts appointed by the American Institution of Mechanical Engineers. In this connection the following extract from a speech by the late president of the Board of Trade would seem to be appropriate: "It will, in fact, be apparent to all close observers that a country which fails to regulate and foster its industries in the national interest cannot in the nature of things long survive the rivalry of another country where the industries are so regulated and fostered."

The Shafting Anomaly

The only detail of the engines proper affected by the surveys is the shafting, and the following is an analysis for a set of triple-expansion engines with cylinders 25 in., 41 in., 68 in., by 48 in. stroke and 180 boiler pressure:—

Diameter of Crank and Thrust Shafts

Board of Trade	=	12.76
Lloyd's	=	13.32
British Corporation	=	13.08

Diameter of Tunnel Shaft

Board of Trade	=	12.12
Lloyd's	=	12.69
British Corporation	=	12.42

In determining the diameter of propeller shafts, each of the three surveys adopts a different basis. Lloyd's and the

British Corporation consider the diameter of the propeller—the British Corporation the block coefficient of displacement of the vessel, whilst the Board of Trade consider neither. Assuming a propeller diameter of 17 ft. 6 in., and a block coefficient of displacement of .78, at four-fifths moulded depth, diameter of propeller shaft is by:

Board of Trade	=	13.47
Lloyd's	=	14.29
British Corporation	=	14.67

That is to say, a shaft to the Board of Trade requirements would be deemed 22 per cent. too weak by the British Corporation, and 16 per cent. too weak by Lloyd's. In practice the shafting of a cargo boat is practically never made to the rules of the Board of Trade, as when the machinery is built to the Board of Trade survey it is invariably associated with either Lloyd's or the British Corporation. If, therefore, these two surveys could see eye to eye, and bring their shafting rules into line, a great advance would be made towards completely standardizing the reciprocating engines of a cargo boat.

With the advent of the geared turbine, and its probable extended use in the near future, it might reasonably have been expected that the various surveys would at least have formulated rules on a common basis. Such, unfortunately, is not the case. Lloyd's and the British Corporation adopt shaft horse-power, the Board of Trade indicated horse-power; Lloyd's rule giving the larger shaft. This state of affairs is perhaps not surprising in view of the fact that aloofness has hitherto been a national characteristic. Force of circumstances will compel us to modify this attitude, and to recognize that friendly co-operation will be the factor which will determine whether we sink or swim in the coming great race for industrial supremacy.

Industrial Methods Revolutionized

Broadly speaking, industrial methods in Great Britain have been completely revolutionized since the war began, because we have been driven to recognize the dominating influence of intelligently directed energy as a factor in the economics of production, and it is unquestionable that the magnificent response to the national demand for colossal quantities of war material resulted from the cultivation of intelligent effort and concentration of organized method. The actual ascertainment of what is possible has been accompanied by an industrial awakening after a dangerously prolonged sleep, and as a fortunate consequence we shall be immeasurably better able to face possibly perilous competition than ever before, provided we sustain our efforts and profit by our experience. Intelligent direction increases the useful efficiency of labor enormously, so that by concentrating on method, employing the most suitable equipment obtainable, and organizing physical effort, such a high rate of production can be obtained as to demonstrate without a shadow of doubt the certainty of an employer being able to pay high wages, but labor must respond with unrestricted production and enthusiastic co-operation. This does not mean great physical effort by labor, but reasonable and continuous effort during a full working day.

In this connection the war has revealed the high standard of useful efficiency attained by women, especially as workers of machine tools, and to their lasting credit be it said that the steadily progressive production in many munition factories is due entirely to the unceasing desire on the part of the women always to do their best. To obtain all that is commercially possible from standardized production it is necessary to manufacture continuously a given article in the best way by the best means at the best speed, whereby the efficiency of each factor is unity. The greater the number manufactured, the less becomes the percentage of attendant expenses. Therefore, in cases where the value of the article is considerable, and the demand great, the commercial success attainable may be phenomenal. Quantity is a controlling factor in all cases, so that maximum success in the standardization of marine engines can only be obtained by the cooperation of the greatest number of builders.

Classification of Propelling Machinery Parts

Merely as an illustrative example let us consider the position on the North-East Coast. The various engineers who specialize in cargo boat machinery produce collectively, say, 200 sets of reciprocating engines per annum. The following is a rough classification of the parts of the main engines only:—

MAIN DIVISIONS OF ENGINES

I—Cylinders	
Cylinders	600
Covers	600
Liners	200
Pistons	600
Valves	600
II—Columns	
Columns	1,200
Guide plates	600
Guide bars	1,200
III—Bed-Plate

Taking the steel forgings and adding the thrust, tunnel, and propeller shafts, the approximate total weight would be about 14,000 tons. If this amount were concentrated at a convenient centre, the steel cast, the ingots forged, and the forgings rough turned, and if the works were of such size that this demand were only a portion of its output, then the cost of production would be so low as to enable the engine builders to buy cheaper and to sell cheaper. The destination of these forgings for machining would depend on available facilities and transport. the object being a continuity of operation under the most favorable conditions possible. The heavy castings would be produced from standard patterns, all prepared in consultation with the iron-foundry management, and the design being standard, the foundry management could with confidence provide the best labor-saving tackle. When delivered to the engine works the castings would be dimensioned by means of standard apparatus, and machined from continuous supply. The tens of thousands of engine valves, fittings, and other details would be classified and manufactured in bulk in specially equipped departments in the best ways, by the best means, and at a cost quite unapproachable by present methods.

Purchase, as Against Manufacture

In cases where an aggregation of parts is not sufficient to secure the benefits of production in bulk, those parts should be purchased from manufacturers whose business it is to produce such parts. For example, take condenser ferrules. A condenser ferrule machine can produce 400 per hour. Even if the yearly demand were half a million the machine would produce them in about 1,200 hours, or, say, 24 working weeks, thereby being operated at half its capacity. Complete standardized production of ferrules and similar details would involve the use of the greatest number of automatic machines that could be supervised by one skilled operator and one or more unskilled assistants. One skilled machine setter and three unskilled assistants could probably manage up to 20 automatics. Therefore, the difference between one machine working half its time with one operator and 20 machines working continuously with four operators is an indication of the possible savings by organized manufacture in bulk.

Take as another example the large bolts, such as are required for main bearings, piston rods, and connecting rods, and which would aggregate about 10,000 per annum. So great a number of practically similar articles would admit of the purchase of special turret lathes capable of finishing bolts up to 5 in. diameter, with provision for completing all operations from the first rough cut to the final screw-cutting and finishing, and if the number of machines were adjusted to maintain their full working capacity the cost of production would again be very favorable.

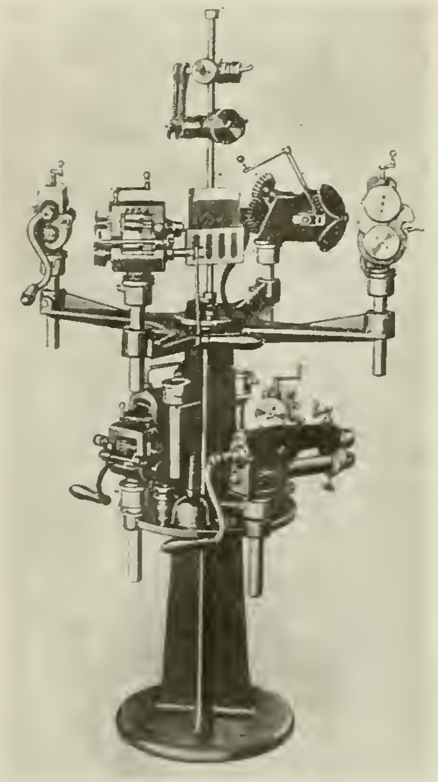
These few examples indicate the possibilities of standardized manufacture as applied to cargo boat engines. The system is co-operative, and is the direct antithesis in its inception and in its results to the destructive competition which has been so rampant and ruinous in past years. In manufacture, the day of conservative and scattered individual effort is over—it leads to certain ruin. Success lies only in concentration by collective effort and the pooling of individual interests for the common good.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

REVOLVING MACHINE STANDARD

THE device illustrated is designed to conserve space and afford increased convenience of operation in metal working shops where various machines are in use intermittently by different workers. It is known as the Hold-all revolving machine standard, and is built by the Peck, Stow & Wilcox Co., Cleveland. A revolving turret is fitted to the upper part of the standard with accommodation for four machines, the proportions being such that four operators have ample room for simultaneous use of the machines; the machine holders can also be raised, lowered or revolved to suit the convenience of short or tall operators or in accordance with the work in progress. The distance from floor to working edge of machine rolls is 40 in. A convenient locking lever is provided for retaining the turret in any position.



REVOLVING MACHINE STANDARD.

The lower shelf has accommodation for four additional machines interchangeable with those in the revolving turret. It also provides handy accommodation for oil cans, tools, etc. Two larger machine posts are accommodated on brackets below revolving turret, making a total of ten posts carried by the standard. The shipping weight of the device is 268 lbs.

PLATE PUNCH TABLE

THAT the question of increased output from shipbuilding yards is receiving attention from makers of various items of equipment is evidenced by the engraving herewith, illustrating the Lysholm plate punch table which is being built by the Norbom Engineering Co., Philadelphia. It is designed for the purpose of facilitating the punching of steel plates, and is constructed in the form of a traverser of approximately twice the maximum length of plate to be handled. Four tracks are provided on which the table travels to and from the punching machine.

The plate is supported by ten shafts fitted with discs on which the plate rests, the four shafts at the centre being geared together through the medium of chains and bevel gears, so that by raising the lever in his right hand the operator moves the ratchet plate to the left, and by depressing the lever, moves the plate to the right. A similar lever at his left hand coupled to a shaft lower down causes the traverser to move bodily to or from the punch. The punch itself is operated by a trip pedal at the operator's foot, or otherwise as desired.

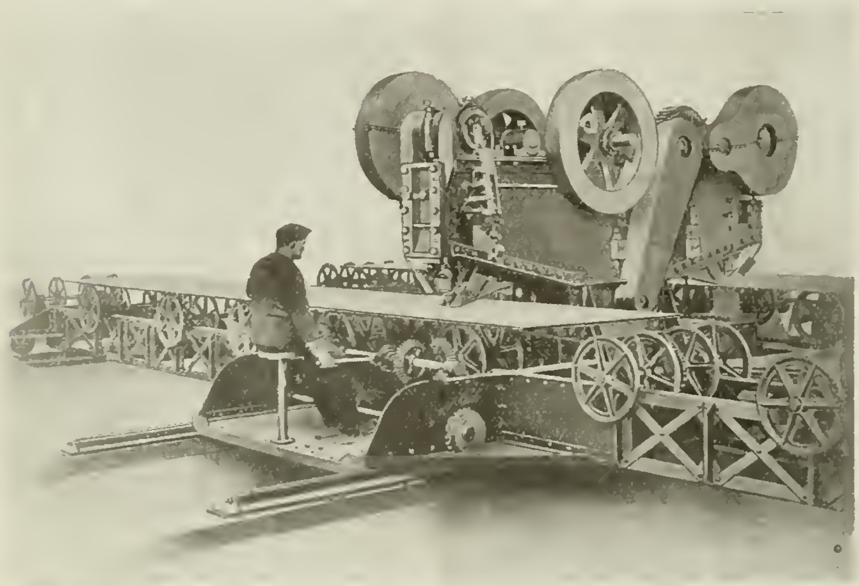


PLATE PUNCH TABLE.

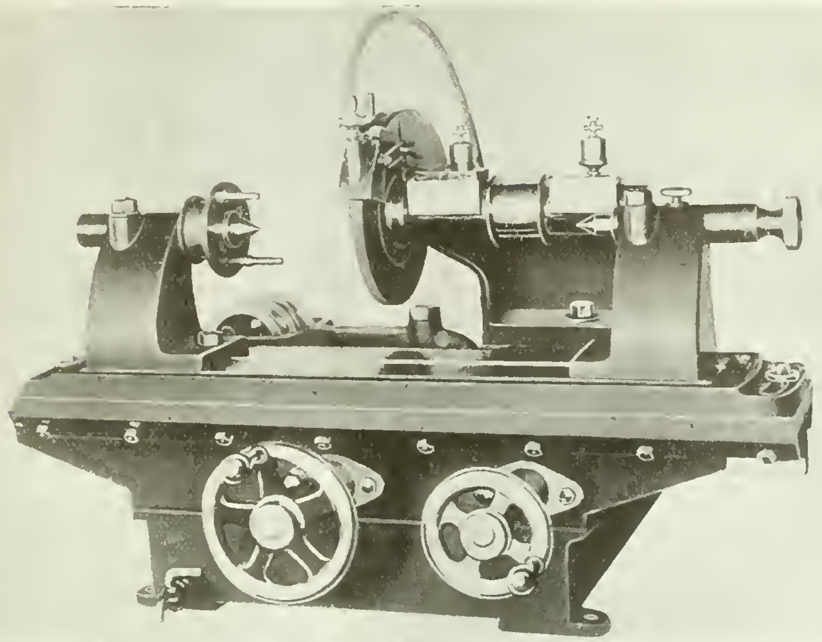
Roller bearings and similar mechanical refinements are employed throughout to insure ease of operation to such a degree that one man can easily handle plates in half the time required with older methods. The size or plate which can be handled is from ¼ in. to 1 in. thick up to 25 ft. in length and 8 ft. wide.

ANTI-ACID VALVES

THE Lunkenheimer Co., of Cincinnati, Ohio, state that during the past year there was an exceptionally good demand for valves made entirely of iron for use in handling cyanides and other solutions which attack metals having copper as their basic element, and which consequently could not be handled by brass valves or valves having any part made of brass. This company, we understand, have supplied a large number for use in dye and chemical manufacturing plants, but the demand was not confined to these sources, as quite a number were also supplied for use in mines, oil refineries, tanneries, pulp and chemical fibre mills, canning and packing establishments, etc. In the manufacture of these all-iron valves, a composition is used that is claimed to be exceptionally free from impurities, resulting in solidity of grain structure which insures great strength and makes the castings more resistent to corrosion and chemical attack. For handling the more severe solutions, such as caustic soda, caustic potash, soda-ash, and other similar alkaline liquids, the company employ a composition known as "Lunkenheimer Nickel-iron." The exceptional acid resisting qualities of this metal and the long and satisfactory service rendered has led many to use valves made of this material even for the weaker solutions. The standard line of Lunkenheimer All Iron Valves includes "Ferrenewo" Globe, Angle, Cross, and Check Valves in sizes as small as ¼-in., and up to 2 inches; cross valves, sizes 2 to 12 inches, inclusive; "Clip" gate valves, as small as ½ inch and up to 6 inches; "Victor" gate valves, sizes 2 to 12 inches, inclusive; quick opening gate valves with lever, sizes ½ to 12 inches, inclusive, and check valves up to 12 inches inclusive.

UNIVERSAL CUTTER AND TOOL GRINDER

SIMPLICITY of construction combined with a wide range of work capacity is a prominent feature of the grinder shown in the accompanying illustration. It is designed for grinding small tools, fixtures, gauges, etc., and will admit work up to 10 in. dia. and 15 in. between centres. All feeds are by hand, the cross-feed of 6 in., having micrometer adjustment graduated to .0005 in., which greatly facilitates the attainment of essential accuracy in tool work.



CUTTER AND TOOL GRINDER FOR BENCH OR COLUMN.

The wheel spindle is 1 in. dia. mounted in phosphor bronze bearings 3½ and 3 in. in length, which insure a rigid drive. The driving pulley is 3 in. dia for 1¾ in. belt, and the maximum size of wheel carried is 8 in. dia. x ¾ in face. Work centres are each ⅞ in. dia., the tailstock centre being provided with quick adjustment. Internal grinding is performed by means of a special attachment which is clamped to the wheelhead. The internal grinding spindle runs in ball bearings. The machine is regularly equipped with pump of original design, a lubricant reservoir being provided in the base. Regular equipment consists of one face plate, 9 in. dia., threaded to hollow spindle of headstock and fitted for No. 2 Morse taper; internal grinding attachment; two-speed countershaft; one 8 in. x ½ in. emery wheel. While specially designed for bench work, the machine is furnished with or without floor stand.

This machine is marketed as Matson's Cutter and Tool Grinder, by Factory & Mill Supply Co., Boston, Mass.

TURBINE GEARING

By D. Street.

IN TURBINE reduction gears for ship propulsion the width of the gear must of necessity be very great as compared with the pitch and the diameter, and wherever this condition exists the difficulty of maintaining an even working pressure over the whole width of tooth surface is enormously increased. The unavoidable minute irregularities in the cutting of the gear may easily cause the burden of the load to be taken by only a small part of the total width of face at a time; the incidence of the load swaying from side to side of the gear at each rotation; while the torque in the pinion itself, which can never be entirely eliminated, may cause that part of the tooth-face nearest the turbine to take permanently an undue share of the duty. From these circumstances springs the liability of the turbine reduction gears to vibration, noise and unexpected breakage, and the necessity for employing gears of a larger pitch, strength, and weight than would otherwise be necessary.

The problem is, however, by no means insoluble. Macalpine was the first to tackle it seriously. His original arrangement was one in which the pinion was carried in a rocking frame which permitted it to give a little under extra pressure at either side, and so maintain an equality of pressure across the tooth-face. Later hydraulic compensating support was substituted for the mechanical support.

Excellent results have been obtained from this method of automatic self-alignment of the pinion to the wheel, but more recently the problem has been attacked from the other side by building a wheel which will adapt itself to the pinion. The gear is built up of a number of plates machined to a form which gives them the desired degree of lateral flexibility. These plates are put together, engaging solidly at the hub, and also engaging on a narrow edge at the periphery. When so built together, they form a solid cylinder, which can be spirally cut in the ordinary manner. After cutting, the edge engagements are relieved with a small dividing tool, so that each disc is operated independently, and is free to deflect laterally under the side pressure which results from its diagonal engagements with the pinion. The parts are so proportioned that this lateral deflection can at no time involve fibre strains which could possibly cause destructive fatigue. A very small amount of this lateral deflection is sufficient to afford the desired distribution of load, and this amount can easily be given without approaching dangerous periodic strains.

The commercial development of this gear is already well advanced. About 72 sets of the gearing have been applied to turbo-generator drives, and some of these have now been in service one and a half years; about seven sets have been fitted to ships which are now in service, some of them having been long voyages. It is stated that in all of this practical experience no case of trouble with gearing has been developed, and no appreciable deterioration of gears has been observed. Contracts are said to have been closed for machinery for the propulsion of 70 ships, aggregating 215,200 horsepower.

Whether self-equalising devices of one kind or another are really essential to efficiency in turbine gearing depends in some measure upon the degree of accuracy which can be reached in the gear cutting process. While the developments with flexible trunnions and wheels have been going forward, important improvements have been made in the method of cutting large gears, whereby the errors in the master wheels are broken up, and so distributed over the surface of the gear as to be practically eliminated.

COOLING IRON CASTINGS

WHERE soft castings are wanted, the rate of cooling has very much to do with the matter. Assuming that the silicon and carbon content are properly proportioned, slow cooling gives the desired results owing to the fact that the carbon very largely separates as graphitic carbon. To secure the best results the sand should be used as dry as is possible to produce a good mould, and there should be a good body of sand of a porous character to back up that forming the actual mould. There is an advantage also in facing the moulds with plumbago, or very finely ground charcoal. This prevents the formation of a siliceous skin on the casting, although the carbonaceous coating to the mould is practically a mere film. Allowed to become practically cold in such moulds, castings should be as soft as the character of the iron will permit. Cast iron is not appreciably amenable to annealing after it has cooled, but during solidification and cooling down to about 300 degs. C., the rate of cooling exerts much influence.

At a picture-house the other day a picture was shown entitled:

"As God Made It."

Immediately following the projection of the title on the screen came the flash:

"Approved by the Board of Censors."

CANADIAN STEEL CORPORATION ACTIVITY

THE decision of the Canadian Steel Corporation—United States Steel Corporation subsidiary, to go ahead with a nine million dollar section of the big plant projected and provided for at Ojibway, Ont., is of more than passing interest, and may be taken as not only justifiable from an emergency viewpoint, but as an indication that post-war opportunities, arising in and to be developed abroad from this Dominion, are of the most assured and substantial nature. All of our steel mills are booked far ahead with orders for munitions steel, even to a degree involving further extension of plant and increasing existing equipment. The rolling of steel rails for which two of our mills are fully equipped is a matter of considerable urgency, and equally so is that of the rolling of ship plates and shapes to meet the needs of our shipyards. The erection and equipping of the plant at Ojibway is certain to be rushed to completion with the least possible delay, the powerful and progressive nature of the interests behind it giving this assurance.

BEST SHIP SIZE TO MEET THE EMERGENCY

WHILE possibly of less moment so far as Canada's shipbuilding programme is concerned, due to the necessarily inland location of what constitutes the majority of her steel shipbuilding plants, it is worthy of note that expert opinion is not at all unanimous as to the size of merchant vessel to be constructed that will most effectually offset enemy submarine activities. Our lake shipyards are restricted to size in their vessel product for ocean service by our canal capacity seawards, but not so the great majority of British and American establishments. Granting meantime, however, that bigger ships than our lake plants dare build will best meet the need, and an exceptionally strong series of arguments appears to justify them, there is, of course, no reason why full advantage should not be taken of our every available capacity, for it will be of the greatest possible value in the present urgency and materially aid in the permanent reestablishment of our Empire merchant marine.

Big Ship Construction Plant Locations

A few weeks ago, our leading illustrated descriptive article—"Intensifying Our Shipbuilding and Marine Engineering Industries,"—urged more attention being given to the establishment of new shipyards from Montreal eastwards, and indicated Sydney and Halifax, Nova Scotia, and St. John, New Brunswick, as desirable locations. The opinion then expressed was that we have as many shipbuilding and ship-repairing plants on our lake shores as there is business for in normal times, although in this crucial period it can truthfully be said that their effort is no mean one. Ocean-going freighters, small, medium and large, cannot come amiss at this juncture, and cannot be pressed into service one moment too soon. However, there seems to be a disposition to lay overmuch stress on the value of small or medium size craft, and to encourage the building of the latter in plants whose equipment and other constructional facilities are capable of turning out vessels of three or four times the tonnage of the others. To this phase of the present shipbuilding propaganda considerable opposition has been aroused, and as already stated the attitude adopted has much to commend it, if not to wholly justify it.

A committee of shipping experts in Manchester, England, in a report recently made public, have the following to say on the preference being given small ship construction as against that of large ones where the facilities and equipment are available:—

"The policy of small ship construction can only have a most disastrous effect on the nation, the man-power required by the army, and our chances of victory. The Germans claim to be sinking 9,000,000 tons a year and hope to sink still more. Allowing losses by mines and natural causes to balance any exaggeration of the German claims, and assuming that we build one-half the lost tonnage (about two and a half times our pre-war output), and other countries the balance (over five times their pre-war output), we have increased last year's output by about four million tons, equivalent to 1,600,000 tons of cargo capacity per year.

Comparisons in Size and Cost.

"Comparing ships of 2,000 tons and 16,000 tons displacement, carrying 650 and 8,675 tons of cargo respectively, and taking the North Atlantic passage as a basis, we should require to build each year 2,460 of the smaller ships, but only 185 of the larger. The smaller ships would cost $555,000,000, and the larger only $230,000,000. The small ships would use 1,550,000 tons of steel and 575,000 tons of timber, and would consume 6,750,000 tons of coal on the outward voyages per year. The larger ships would absorb 1,030,000 tons of steel and 382,000 tons of timber, and consume only 1,560,000 tons of coal.

Men and Material

"The number of men employed in building the ships, including making and handling steel and other materials, would be 635,000 for the smaller ships and 285,000 for the larger. The coal consumed would account for 45,000 men for the small ships as against 10,500 for the large. Thus the larger ships would release about 380,000 persons for other national service. Moreover, the larger ships would require 60,000 fewer mariners. Again, the percentage of loss, both in number of ships and in cargo-carrying capacity, will be greater with small ships than large, and the former will produce greater congestion in ports.

"The policy of the small ships, therefore, is all wrong. All our shipbuilding energies should be directed towards building the largest ships our various yards can efficiently handle."

INDUSTRIAL NOTABILITIES

LOUIS MARCEL LYMBURNER, president and general manager, Lymburner, Ltd., Engineers, Brass Founders & Munition Manufacturers, Berri and Commissioners Streets, Montreal, was born at St. Henry (now Montreal), September 7, 1871, son of Marcel E. Lymburner, ex-Mayor of St. Cunegonde, and Mathilde Guyard de Fleurie. His ancestors were of Scottish origin, having come to Canada with a Scottish regiment in 1793; his great grandfather, Adam Lymburner, was one of the promoters of the Lachine Canal.

After receiving his education at Belmont School, Montreal, Mr. Lymburner commenced his apprenticeship with his father, who, for over forty years, carried on business as brass founder, finisher and plater. Here he worked through every department of the business, remaining till 1893. For the next two years he was employed by the firm of Robert Mitchell & Co., after which he returned to his father's business to succeed him,

LOUIS MARCEL LYMBURNER.

and has been engaged in this business continuously for 21 years. In 1907 the business was incorporated under the present name, with Mr. Lymburner president and general manager.

The Company's plant is equipped with the most modern machinery for engineering and machine work, brass moulding, finishing and plating. A special line of product is fire station equipment, the Company holding numerous patents covering such features as harness release, horse-loosening and door-opening devices specially designed for time-saving.

Mr. Lymburner married Marie Louise Dextras dit Bezier, daughter of Frederic Dextras dit Bezier, Montreal, November 17, 1891; the family consists of three sons and eight daughters. His principal recreation is motoring.

He is a member Montreal Board of Trade and Chambre de Commerce du District de Montréal. In politics he is Independent, and in religion, Roman Catholic.
His address is 721 Northmount Ave., Montreal, Quebec.

The General Market Condition and Tendency

STEEL prices are still advancing steadily, being helped in their upward movement by conditions in the States. As indications point to the American Government paying nearer current prices for steel than was originally fixed, it is likely that the upward tendency will be more pronounced. Indications also point to the Government's requirements being very heavy, which will result in a greater shortage of steel for other purposes, adversely affecting the private consumer. Canadian manufacturing interests will also be affected as they depend at the present time to a large extent on American steel, domestic mills being engaged more or less on war business. Prices of plates have again advanced and the end is not in sight. The scarcity of plate is a serious matter, as it is delaying the construction of ships. Price at present is no object as long as plates can be obtained. Blue annealed sheets have also advanced, while higher prices on black sheets and possibly tubes are looked for in the near future. The scrap metal market is quiet at unchanged prices. Prices of steel and cast scrap are firm, but copper and brass continue weak. In the non-ferrous metals tin has made a sharp advance, due to shortage of supplies and possibility of the submarine campaign causing losses of metal. Lead is also higher on account of a scarcity and expected bigger demand in the near future. The machine tool business is quiet, but prospects are improving. The demand is assuming a more normal character. Limited supplies of Victoria foundry pig-iron are available at $50, but the market is very firm and further advances are looked for.

Montreal, Que., May 14, 1917.—Industrial interests are closely watching developments which are gradually transforming conditions in the United States and which will eventually affect the general situation in this country. The recent war measure entailing increased taxation in that country, will undoubtedly result in great changes, the extent of which it is impossible to foretell at this time. Canada will naturally be affected by any changes that may take place across the line, as conditions here are governed to a great extent by those prevailing in the United States. The army and navy program of the American Government may curtail the shipment of considerable material intended for industries in this country, but it is understood that every facility will be provided to prevent any possibility in the restriction in the output of munitions or other war necessities, both in this country and the States. The general activity of present industrial developments is gradually undergoing change for while little reduction has been noticed in the production of the smaller types of munitions, there is a noticeable falling off in the manufacture and prospects for further business in the larger sizes of shells. This is however, is being somewhat offset by the appreciable increase in the activity displayed in shipbuilding circles, this industry promising to attain the same proportions as that of the shell industry, and one that may prove more permanent.

Pig Iron

Further advances are still a feature of the pig iron situation and the market is very strong with the tendency ever upward. The Canadian producers are virtually out of the market as very little metal is available at any price. The advances noted on the American market range from $1 to $5 per ton; the quotation of composite pig iron being

$41.935 per ton, an advance on the week of over $1.25 per ton.

Steel

The situation throughout the steel industry is rapidly approaching a point where it will be practically impossible for any but war interests to continue producing on anything like the scale hitherto existing. This abnormal condition is being created through the excessively high cost of all raw materials and the necessity of the different governments to curtail or eventually stop production for all domestic requirements other than those essential to the prosecution of the way. Even should the opportunity be available for domestic interests to secure material for their future requirements, the prohibitive expenditure entailed in the purchase of the necessary product makes it imperative that operations be curtailed or possibly cancelled until a more favorable period. The demand for all grades of steel seems to have increased and this is largely due to the fact that many producers are virtually out of their respective markets, conditions rapidly becoming such that certain grades of steel must be produced in larger quantities and it is up to the different producers to get this material out irrespective of what their particular plant has hitherto done. In this respect, the American government has apparently put it up to the steel industries to produce the steel, or other means will necessarily have to be found to meet the requirements of the situation. Further advances in basic iron may shortly be reflected in certain grades of steel as the conditions prevalent in pig iron govern, to a large extent, the prices existing in the different steel circles.

Marked scarcity of sheet bars and inability of mills to obtain supplies has resulted in a further advance on the New York market, an advance of $5 per ton bringing the current quotation up to $90 per ton. The price on iron bars, New York, has been advanced during the week from $3.419c to $4.169c, this being $15 per ton above that of last week. The inability to obtain sheets keeps the market in a very strong position but local dealers report a practically closed market on these lines. The plate mills are making every effort to supply the requirements of the trade but their filled up condition does not permit them to take on any further business, and in addition there is always the possibility that existing orders may have to be set back to make room for government orders. Small mills which can handle material can obtain almost any price they ask. Local dealers have again revised their quotations on plates, the advance being quite stiff, and an indication of what early future conditions may be. Plates ¼ to ½ inch are now quoted at $9 per hundred; heads $9.30 to $9.65; and 3-16 inch tank plates $9.10; these prices being approximately 1½ cent per lb. higher than those of a week ago. Further price adjustments, on other grades, are expected in the near future.

Metals

With the exception of tin and antimony, the general metal situation is very firm. The market is still dominated by prospective American developments. Copper has apparently taken on strength but prices do not conform with visible conditions. Tin has made a considerable jump, due to several conditions that combine to excite the market. Spelter is held firm by the high cost of production but the market is quiet. Lead is firm and steady. Antimony is stronger after a period of weakness. Aluminum is firmer locally but slightly weaker abroad.

Copper.—Following the advance early in the week the market has again become quiet but the firmness remains. Large consumers are reluctant to buy at what seems to them to be inflated prices, until further developments give a more reliable tone to the actual situation. At the same time there appears to be a certain disposition on the part of buyers to close business for their future requirements; this feature might indicate that an early buying movement on a fairly large scale would be a factor in early trade development. Large producers are well sold for the next several months and reports seem to favor extra heavy buying to cover last half requirements. London is firm while New York is quoting the nominal figures of 33c for lake and electro, and 30¼c for castings; these prices showing advances of 1½c, one cent, and ¾c respectively. The situation here is a little stronger, having advanced ½c during the week, the quotation being 38½c for lake and electro and 37½c for castings.

Tin.—Conflicting reports are current as to the actual cause for the recent strong position of tin; rumors of loss in transport together with the contemplated tariff changes imposed by the United States government are the leading factors for the sharp advance recorded during the past week. The increase in tariff will undoubtedly mean that higher prices will prevail in pig tin and tin products. This metal is at present in great demand owing to the heavy requirements of the governments and domestic manufacturers in preparing for the canning season, and the inevitable need for large supplies of canned foods to carry the country through the coming period of uncertainty. A feature of the present situation is the exceptionally strong London market where the advance of the week has been £12 per ton. The New York market is up 5½c per lb.. the quotation being 64¼c per lb. Local dealers are quoting 63½c, this being an advance of 3c per lb.

Spelter.—The market in spelter is very quiet but firmness prevails; although the situation is unsettled, and buyers and producers are apparently awaiting developments, the undertone is strengthened by the fact that the cost of production is such that much lower prices than those prevailing would entail loss to the smelters. The brass interests are not active buyers and the demand in this direction is comparatively light. Firmness prevails on a quiet market, both in London and New York, the quotation on the latter being 9½c per lb.

Lead.—The market in lead shows little change although increased irregularity is evident in the general tone of the situation; the strength however, is well maintained with slightly higher prices prevailing on the open market in the States, the nominal quotation during the week having advanced ½c in St. Louis, making the price of 10½c general for independent quotations. Dealers here report a steady and firm market.

Antimony.—Reports on conditions in the antimony market are very conflicting. After the recent decline of over 10c per lb. the situation has apparently steadied and is actually showing strength but the reasons for so doing are varied and also uncertain. No increased activity has been shown on the part of the consumers but the offerings of metal seem to have fallen off. While the current quotation in New York is nominally 26c and one cent lower than the corresponding period of last week, this price is still several cents stronger than a few days ago. Firmness prevails on the local market.

Machine Tools and Supplies

No change is noted in the machine tool situation and if anything the market is quieter than last week. The market for equipment for large shells is practically stagnant and it is anticipated that business in the 8 and 9.2 in. shells will be almost at a standstill by the first of August, with the possible exception of a few of the larger manufacturers. Fair business is still being carried on in machinery for small shells but general activity in munitions tools is gradually showing a falling off. General domestic trade is very encouraging, considering the high cost of equipment; the demand for wood working machinery for ship building purposes, promises well for the coming months, but this activity is not much pronounced locally owing to the ship yards in this locality being fairly well equipped for present requirements. However, developments in the Maritime Provinces are of a nature that may demand greater supplies of ship building equipment. Prices on all kinds of machine tools and supplies continue firm with an upward tendency, due to the continual advances in the cost of raw and semi-finished materials.

Scrap

The general tone of the scrap situation is very unsettled, the market being very erratic and subject to sharp and uncertain fluctuations following the developments in political circles. The effect these conditions are having on the market is to create a situation where quotations are only nominal, and liable to change at any time. The demand for all grades of scrap is good, more particularly composition scrap, and the prices on tin and kindred scrap have advanced following the strength of the tin situation. The local market is also affected by the general conditions, with the week's quotations showing strength in iron and steel scraps and slight weakness in old metals. Old coppers have declined one cent, the prices quoted being 21c for light and 25½c for heavy and crucible. Machine composition on a similar decline is quoted at 21½c. Old boiler plate, on a ½c rise, is quoted at 19c per lb. Rails are now 19c, this being an advance on the week of 2c per lb. Machine cast iron is up one cent., the price asked being 22c per lb.; while malleable scrap at 17c is two cents stronger than last wek. Wrought iron pipe has advanced 1½ cent, the current quotation being 14c per lb. The price of scran zinc shows a drop of one cent, the price asked being 8c per lb. Old and scrap aluminum have declined 4c on the week, the present quotation being 32c per lb.

Toronto, Ont., May 15.—Industrial expansion in this city and district is proceeding in a most gratifying manner. In the Ashbridge's Bay the new steel plant is rapidly approaching completion, while in the vicinity it is proposed to establish a shipbuilding plant. The aeroplane factory now under construction will be in operation in a few months, while an extensive plant nearby at Camp Borden will son be completed. Although it is unlikely that more orders for 9.2 in. and 8-in. shells will be given out, it is understood that there will be no falling off in contracts for smaller calibre shells in the meantime.

Steel

A report is again current that work on the new Canadian Steel Corporation plant at Ojibway, Ont., will be proceeded with shortly. It is understood that a rod mill will be installed while bars and small shapes will also likely be among the first products manufactured. The demand for steel is as insistent as ever and shows no indication of diminishing. The most disquieting feature at the present time is the difficulty in obtaining steel for manufacturing purposes and for buildings. The Canadian steel companies are engaged upon the production of steel almost entirely for munitions and other war purposes, leaving the private consumer largely dependent upon the American mills for the required materials. Developments in the States are making it increasingly difficult for the private or manufacturing consumer to get steel, as the American Government requirements are assuming large proportions. Government buying is assuming a more tangible form and indications are that later purchases will be at nearer to market prices than the figures original fixed. This will tend towards more settled conditions but will at the same time have a tendency to stiffen prices and help in the general upward movement.

The expected advance in plates has materialized, the local price being now 8c for ¼-in. to ½-in. and 8.10c for heads and tank plates. Much higher prices may be looked for as the demand is extraordinary and will continue to be so for many months yet. The fact that 11c mill was recently paid on ship plates for delivery during the first quarter of 1918 is a clear indication of what may be expected. The demand for ship plates is so urgent that it is entirely a question of getting the material, the price being practically no consideration. The situation is such that there are really no set prices on plates, sales being governed almost entirely by the deliveries wanted, tonnage and former relations existing between the buyer and the mill.

Prices of blue annealed sheets No. 10-16 gauge have advanced, No. 10 being now quoted at $7.90. Higher prices on black sheets are expected in the near future. The new demand is abnormally heavy and very high prices are being paid for black and galvanized sheets for fairly prompt shipments. Sheet bars continue to advance and a market price of $100 may be expected. This figure has already been reached on some special business for quick shipment.

The U.S. Steel Corporation unfilled tonnage on April 30 amounted to 12,183,083 tons as against 11,711,644 on March 31st. This is a direct indication of the position of the steel market in the States. The mills are overcrowded with work of all kinds and with exceptionally heavy government orders in sight, the prospect of meeting the needs of the private consumer is not bright. Government work is being given preference, which is probably the main reason for the accumulation of business with the Steel Corporation and independent concerns.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Pig Iron

A quotation of $50 a ton has been issued on "Victoria" pig iron, but available supplies are somewhat limited. Nearby pig iron is growing scarcer. Most furnaces are unwilling to accept orders even for small lots which require prompt or near prompt delivery unless the buyer is an old customer. Price in a majority of cases is less to be considered than the question of getting iron at all and never before have deliveries been contracted for so far ahead. Prices are still advancing. Grey forge Pittsburgh $40.95, Basic Valley, $42, and Bessemer Pittsburgh, $44.95.

Scrap

With the exception of some little activity in cast scap and steel scrap the market on the whole is quiet. Prices are generally maintained at current quotations.

Machine Tools

A gradual readjustment seems to be taking place in the machine tool business. Very little is heard of munitions these days, although some machine tools are occasionally being purchased for shell or fuse plants. More attention is now being paid to other prospective spheres of action. Shipbuilding is perhaps offering the best chance of business for heavy equipment, although as old established plants are being largely utilized for the shipbuilding campaign, this lessens demand for machinery. Specifications are out for the proposed shipyard on Ashbridge's Bay to be backed by the Imperial Munitions Board. The plans which are only partially completed call for a machine shop plate shop and blacksmith's shop, etc. Some new equipment will likely be required for the shipbuilding plant at Welland. The Canadian Aeroplanes, Ltd., have not purchased all the machinery for their new factory being built in Toronto, while the Semet-Solway Process Co. have prepared plans for a large plant at Amherstburg, Ont.

Supplies

Business continues active at firm prices. Lead sheets have advanced 1c per pound in line with all lead products. Linseed oil is very strong again and prices are advancing due to the high cost of flax seed. The demand for machine shop supplies is of a general order, particularly for belting drills, reamers, taps and dies, files, pullies, etc.

Metals

The metal markets are stronger this week, the feature being a sharp advance in tin, while lead is also higher. The improvement in the situation is due largely to a clearer indication of the American Government's policy in regard to its purchases of metals, and prices to be paid. The advance in tin due to the low visible supply and fear of cargoes being lost. Lead is higher on account of scarcity of supply and expectation of Government requirements, which it is presumed will be heavy. The copper market is firmer, but quotations are unchanged in the meantime. Spelter, antimony and aluminum are unchanged. Solders have advanced.

Copper.—The market is firmer but prices are unchanged and nominal. The indications of a further decline in the price of copper which were prominent a week or two ago have disappeared altogether and a recovery to the former high level looks likely. Producers state that consumption is in excess of production and that the copper requirements of the world for the last half of this year will be materially larger than they have been during the first six months. Local prices firm and unchanged. Lake and electrolytic 38c and casting 37c per pound.

Tin.—Prices continue to climb upward both in London and New York. The reason for this extraordinary advance is traceable to a low visible supply and also increasing risk of shipments. The market is inclined to be excited over the situation and prices may go still higher. Tin has advanced 9c locally and is now quoted at 68c per pound.

Spelter.—It is reported that the zinc

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa. British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing. London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin. Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbegd No. 4, Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Care British Consulate General, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

producers have named a price to the American Government of 11½c a pound delivered for grade A, 11c for grade B and 9c for grade C. It is understood that in accordance with this arrangement 25 million pounds have been contracted for with delivery over the next twelve months. As a result the market is firmer but dull. Local prices unchanged at 12c per lb.

Lead.—The market is dull but very firm and prices are higher locally. As the leading interests have withdrawn from the market for the time being they have left it bare of supply and consumers who must have metal for current needs have been obliged to pick up where they could. Lead has advanced ½c locally and is now quoted at 13½c per pound.

Antimony.—The market is firmer than last week but the price is unchanged and nominal. Local price 30c per pound.

Aluminum.—The market is quiet for spot metal and quotations unchanged at 68c per pound.

Solders.—Prices of solders have advanced in line with tin and lead. Guaranteed is now quoted at 39c. and strictly at 37c per pound.

Sydney, N.S., May 9.—The week has been marked by a series of increases in wages. The Royal Commission appointed to enquire into the wage question at the mines of the Dominion Coal Co., gave as its formal finding an increase to the mine workers of ten cents per day in the case of all men earning $2.50 and under per day, plus an increase of 12½ per cent. to all workmen. The increase of 12½ per cent. in the case of the men earning $2.50 per day and under is applied on top of the increase of ten cents per day. A recital of the increases given to the workmen of the Dominion Coal Co. since June 1, 1916, is rather impressive. At that date an increase of six per cent. was granted, followed in November by a further increase of fourteen per cent., and followed by the increase just referred to of 12½ per cent. and ten cents per day to the men under $2.50 per day. In addition, the company are paying a 5 per cent. bonus on the earnings of all producers who work 22 days out of each working period of 24 days. In 1908, when the Shortt Conciliation Board gave the award which has formed the basis of agreements since that date, the minimum rate for day labor at the mines was $1.38 per day. Men of this class will now receive $2.41 per day, so that the increase during a period of less than ten years has been almost 75 per cent. Other classes of labor have not been increased quite so heavily as the unskilled day laborer, but in no case has the increase in the wages of mine workers during the past decade been much under 50 per cent.

At Springhill Mines, the Dominion Coal Co. have also made an increase, effective, as in the case of the Glace Bay mines from May 1. At Springhill, an increase of ten cents per day is given to men below $2.50 per day, and in addition an increase of ten per cent. is given

(Continued on page 525.)

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Vancouver, B.C.—The Phoenix Iron Works were destroyed by fire recently.

Hamilton, Ont.—The Bowes, Jamieson Co. will move their shell plant down to the Baines Carriage Works in Hamilton East.

Kingston, Ont.—The Kingston Shipbuilding Co. has practically purchased the plant of the Kingston Foundry Co., adjoining its premises.

Toronto, Ont.—Fire on May 11 did damage, estimated at $250,000, to the plant of the Cluff Ammunition Co., Sterling Road.

Niagara Falls, Ont.—Operations on the Chippawa-Queenston Hydro-Power canals have been started. The work will be rushed owing to the demand for additional power.

Windsor, Ont.—It is reported that the Canadian Steel Corporation will proceed with the construction of a steel plant at Ojibway. Present arrangements call for an expenditure of $9,000,000 in the erection of buildings and installation of machinery.

Amherstburg, Ont.—The Brunner-Mond Co., a subsidiary of the Solvay Process Co., of Syracuse, N.Y., are having plans prepared for a plant to cost $2,000,000.

Montreal, Que.—A new and important pulp and paper company has been organized in this city with a capital of one million dollars. The concern proposes to erect and operate mills on the Madeleine River, in Gaspe County, on the south shore at the mouth of the St. Lawrence River.

Chatham, Ont.—The foundry at the old Defiance Iron Works, which is now the Canadian-American Pump & Well Machinery Co., located on Lacroix Street, and which has been idle for several years, is again under operation under the management of Woods Bros., who for several years have operated the Ideal Foundry on Princess Street.

Toronto, Ont.—The shipbuilding plant which is contemplated for the Ashbridge's Bay district will be backed by the Imperial Munitions Board. The plans are already well developed, so much so that prices are being obtained on the chief equipment required for the various departments of the enterprise.

Fort William, Ont.—Mayor Murphy announces that work will be begun by June 1 on a 150-ton pulp mill on the site here adjoining the Canadian Government Railways docks. The Kaministiquia Power Co. will supply 8,500 h.p. and the city a million and a half gallons of water. As soon as the pulp mill is running a 100-ton paper mill will be erected by the company.

St. John, N.B.—In order to increase the production of the plant and improve the quality of its output, the Nashwaak Pulp & Paper Co. has decided to enlarge the works and add new machinery thereto. Good progress has already been made on the new developments. The company manufacture what is known as bleached sulphite wood pulp, the basic material being obtained from the spruce products of their own forests.

Montreal, Que.—The Brompton Pulp & Paper Co. has decided to abandon certain plans for extensions for the present time The company has made all arrangements for the development of one of its water-powers and work was to start shortly. The company owns five water-powers, three of which have been developed. The plans drawn in connection with the development of a fourth, it is understood, called for the expenditure of $500,000 to $750,000, and the company had made financial provision for the amount required.

SYDNEY LETTER

(Continued from page 524.)

to this and all other classes of mine labor. The men at Springhill are not satisfied with the extent of the increase given, and it is expected the Royal Commission appointed to look into matters at Glace Bay will review the Springhill situation also.

The Commission is at the time of writing sitting at Sydney Mines, where it is enquiring into the wage increase asked for by the workmen of the Nova Scotia Steel & Coal Co. It has not as yet been announced whether any settlement has been arrived at, but some increase in wages at these mines is also a foregone conclusion.

The Royal Commission has devoted considerable attention to the possibility of conciliation and amalgamation of the rival miners' labor unions, namely the Provincial Workmen's Association and the United Mine Workers of Nova Scotia. It is thought that a new union will be formed, that the present officers of the existing organizations will retire in favor of new officers of a merged union that will take an entirely different name, and be purely a provincial organization under the laws of Nova Scotia. Whether this amalgamation will take place is not quite certain at the moment, but those who are in favor express considerable optimism as to the probability of amalgamation and the results that may be expected to follow. The Dominion Iron & Steel Co. have also announced a ten per cent. wages increase effective May 1.

The work of excavation for the new bye-product coke-ovens at Sydney is now actively proceeding. The Dominion Steel Corporation, both at the steel works and the collieries is stimulating interest in food production by letting out vacant land for gardening purposes, and by providing horses and ploughs. Arrangements are also being made to use the company's purchasing organization to obtain supplies of seed potatoes, fertilizer, etc.

ELECTRICAL

Walkerton, Ont.—The Hydro-Electric Commission will prepare a scheme for a supply of power to this district.

Brantford, Ont.—The Township Council are preparing to enter into a contract with the Hydro-Electric Commission for a supply of power for domestic use and street lighting. A by-law will be drawn up and submitted to the ratepayers.

Kingston, Ont.—Engineer Gordon Kribs, of the Hydro-Electric Commission, has been going over the line from Napanee to Kingston and arranging for the work to be carried on in getting the sub-station and power house ready. It is expected that the line will be finished the last of August.

GENERAL

Peterborough, Ont.—The American Cereal Co. are planning to rebuild their mill, which was destroyed by fire some time ago. The equipment is being purchased by the Chicago office of the company. They will be in the market shortly for boilers and mechanical stokers.

BUILDING

St. John, N.B.—F. Neil Brodie, architect, has prepared plans for a hotel at Moncton, to cost $150,000.

Galt, Ont.—The City Council has given the Hydro Commission an additional 12-foot strip on the city square for the site of its new building.

Montreal, Que.—The Catholic School Commission has decided to call for new tenders in connection with the proposed construction of a new school in Maisonneuve.

Cowansville, Que.—The ratepayers have decided to support the School Board and proceed with the erection of a new academy building. Dr. Rodgers is chairman of the board.

Toronto, Ont.—The Provincial Hydro-Electric Commission have purchased a property adjoining their office building on University to provide for future extensions.

Dundas, Ont.—A number of contracts have been let for the new office building for the John Bertram & Sons. The building will cost $93,000, and the general contractors are P. A. Secord & Sons.

Toronto, Ont.—City Architect Pearse has issued a building permit to the Hydro-Electric Power Commission to erect an addition to their storehouse, foot of Strachan Avenue, at a cost of $75,000.

PERSONAL

B. E. Michel has been appointed city engineer of Kitchener, Ont., at a salary of $1,800.

W. I. Gear, of the Robert Reford Co., Montreal, has agreed to give his services to the Imperial Munitions Board as director of steel shipbuilding, and will deal with all questions relating to the construction of steel merchant ships in this country for the British Government. His office will be in Ottawa.

R. P. Butchart, of Victoria, B.C., who has been appointed director of shipbuilding for British Columbia, will have charge of the building of wooden vessels in that province. **Capt. J. W. Troup**, manager of the British Columbia coast service of the C. P. R., will act as assistant director, with headquarters also at Victoria.

J. H. Welsford, president of the Union Steamship Co., of British Columbia, died recently at his home in Liverpool, England. Mr. Welsford was a prominent shipowner in Great Britain, but frequently visited British Columbia. He purchased a controlling interest in the Union Steamship Co. in 1911.

William Lodge, of the Lodge & Shipley Machine Tool Co., Cincinnati, Ohio, died at his residence in that city on April 30, aged 69 years. He was born in Leeds, England, in 1848, and at the age of 22 went to the United States. Early in 1872 he went to Cincinnati, and in due course became one of the pioneer machine tool builders in that city. Wm. Lodge was one of the first to introduce machine tools made in Cincinnati in England, having established a business connection with Alfred Herbert & Co., of Coventry. In 1893 Mr. Lodge become associated with Murray Shipley, and the present firm of Lodge & Shipley was incorporated.

W. D. Jacoway has been appointed superintendent of the open-hearth and electric furnace departments at the new plant of Armstrong, Whitworth of Canada, Ltd., at Longueuil, near Montreal. He was connected with the open-hearth department of the Dominion Iron & Steel Co., Sydney, N.S., and later was with the Bethlehem Steel Co. at South Bethlehem. More recently he has been associated with C. H. Macmillan in installing and operating an electric furnace and open-hearth plant for the Canada Cement Co. at Longue Point, Que. The new plant at Montreal consists of four Heroult furnaces and two open-hearth furnaces.

TRADE GOSSIP

The Turnbull Elevator Co., Toronto, have the contract for elevators for the new C. N. R. station on Dorchester Street, Montreal.

Philipsburg, Que.—The directors of the Missisquoi Marble Co. have ordered the closing down of the marble plant here for an indefinite time.

St. John, N.B.—During the first three months of 1917 the harbor revenues show an increase over the corresponding

The Bawden Machine Co., Toronto, has been awarded a contract by the Thor Iron Works, Toronto, for 24 cargo winches, 4 windlasses and 4 steering engines.

Contracts for Forgings.—The United States Government has placed contracts for 10,000,000 pounds of steel forgings at approximately 34 cents a pound with the Bethlehem and Midvale Steel Companies. period of last year of $12,623.04.

Canada Copper Corporation, which was organized several years ago as a financing medium for the British Colbia Copper Co., has taken over the assets of the latter concern, which will now pass out of existence.

The Bawden Pump Co., Toronto, have been awarded a contract for nine pumps, ranging from half-million to three-million gallons' capacity per day, by the Colonial Pulp & Paper Co., Vancouver, B.C.

Montreal, Que.—The recent sale reported of the Delmas Pulp & Paper Co. at St. Amadee de Peribonka, Lake St. John, to Messers. Barclay & Theriault, is denied by J. P. Marion, who announces that he has already taken steps to float a new corporation to act on his option.

Record Steel Tonnage.—The unfilled tonnage of the U. S. Steel Corporation on April 30 last was 12,183,083 tons, an increase of 471,439 tons over the previous month, and again breaking all previous records. The April gain compares with 11,711,644 March 31, 11,576,697 Feb. 28, and 9,829,551 on April 30 a year ago.

St. Catharines, Ont.—The possibility of the Dominion Government taking over sections one, two and three of the Welland Ship Canal, upon which work has ceased until after the war, is now quite apparent. An agent of the Government is at present in the city taking inventory of the various plants, and it is understood that his mission is based upon the above-named possibility.

Exports Prohibited.—The British Trade Commissioner in Canada has received a cable from the British Board of Trade, London, stating that exports from the United Kingdom of the following goods are prohibited, as from May 1:—Mineral waters, beer, ale, candles, paraffin wax, iron and steel constructional material, tubes, sheets, etc.; plywood, railway material, resinous substances. Licenses are obtainable for goods in transit through the United Kingdom, now affected by import and export prohibitions, except in neutral ships.

Canada and U. S. in Joint Effort.—Cooperation between the United States and Canada in many lines of national endeavor, the whole designed to aid the allies effectively, are indicated by Sir George Foster, who returned to Ottawa recently from Washington, where for two weeks he participated in the allied conference. There is to be joint effort in regard to production, munitions output, shipbuilding, coastal defence, and, quite possibly, in respect to the regulation of food prices. Sir George says the United States are in the war very much in earnest.

Quebec, Que.—The Great Eastern Pulp Co. has just been organized here for the purpose of erecting and operating pulp and saw mills at Madeleine River, Gaspe County, Quebec. The officers chosen so far are: President, John Mullen, of Bangor, Me.; vice-president, Archibald Hay Cook, K.C., Quebec. There will be a bond issue of $600,000 and a stock issue of a like amount. The pulp mill will have a capacity of 30,000 tons of ground wood pulp annually, and the output of the sawmill will be 10,000,000 feet. The company owns 200,000 acres of timber lands, assuring an adequate supply.

Work on Bridge Span Progressing.—The work of constructing the new Quebec Bridge span, which is to replace that which collapsed in September of last year, is reported to be going on very satisfactorily. About 75 per cent. of the span is now already manufactured in the shops, and according to a representative of the St. Lawrence Bridge Co., there is nothing to interfere with the progress of the work. They have all the material necessary, and have experienced no shortage of labor. It is expected that there will be another three or four months before the span is completed, ready for placing.

Russian Locomotive Requirements Heavy.—Advices from New York state that the Russian Government has sent out definite inquiries for 1,000 locomotives, and is understood to require 2,000 more, a total of 3,000. The placing of these orders as well as orders for cars is likely to be postponed until Russia gets the loan she expects from this country. In the meantime locomotive companies in the U. S. are at work on the orders placed last December by Russia for 300 engines divided equally between the Baldwin and American Locomotive Co.'s. Shipments of some of the engines have already been made. Payment for these engines is guaranteed by the British Government.

More Track for West Front Required.—Canada has been asked to supply another three hundred miles of trackage for the West front. Last winter several hundred miles of rails were sent from Canada to France, and the request for additional trackage has just been made through the Imperial Munitions Board. The matter has been referred to the Dominion Railway Commission, and Sir Henry Drayton has already arranged for some two hundred miles of trackage, which is to be obtained by lifting the Grand Trunk Pacific tracks west of Edmonton, between Imrie and Resplendent, where the line parallels the Canadian Northern line, and where one railway track can be used by both lines.

Opening New Metal Areas.—In mining circles it is stated that influential New York interests may shortly enter into the development of important molybdenum areas in the neighborhood of Quyon, Que. A number of molybdenum properties have been operated with varying success since war demands stimulated demand for the metal. Technical, as well as financial difficulties have had to be surmounted. It is held in connection with the Quyon venture that it

started out under favorable auspices on the technical side, having the advice of distinguished American experts, and that this has facilitated the enlisting of the support of New York capital. If the promise of the present development is verified it will be another instance of the stimulus of war business to the metallurgical industry of the country.

Alberta Coal Mines Increase Tonnage.—Over 4,648,600 tons of coal were mined in Alberta last year. During this period, 107,959 tons of briquettes and 41,950 tons of coke were made. Several small mines have been opened in the Peace River district, and although at present operated on a small scale, it is probable that with the increased settlement now taking place in the district north of Edmonton, these mines will be fairly large producers in the near future. The output of coal for the year 1916 exceeded that for the year 1915 by 1,213,713 tons, thus establishing a record output for the province. There were 282 mines in operation during the year 1916. Of these, two were copper mines, one a shale mine and two hundred and seventy-nine coal mines. Operations were discontinued at the copper ore mines several months ago, and have not been resumed. The shale mine during the year 1916 produced shale from which 200,000 bricks were manufactured.

Mason Regulator & Engineering Co.—A new company has been organized in Montreal, under the name of Mason Regulator & Engineering Co., and has taken over the well known steam specialty business of H. L. Peiler & Co. there. The new company has also acquired the Canadian business of the Griscom-Russell Co. Eldon Macleod, treasurer of the Mason Regulator Co. of Boston, Mass., is president, while H. L. Peiler will act as treasurer and general manager. It is the intention of the new company to manufacture, in Canada, Mason reducing valves and other pressure regulating appliances, as well as "Bundy" steam traps and "Coppus" blowers besides the marine and steam specialties of the Griscom-Russell Co. These include the well known Reilly heaters, evaporators and distillers which enter so largely into marine equipment. All the other agencies controlled by H. L. Peiler & Co., will be retained, the business being carried along on the same lines as heretofore. The new company will have a greatly strengthened organization. Associated with Mr. Peiler will be E. J. Hatton, formerly of the Canadian Allis Chalmers Co., who will have charge of the manufacturing and erection work, while the sales end will be taken under Mr. Peiler's supervision, by E. T. Jeffrey, formerly of the John McDougall Caledonian Iron Works, and H. E. Kirkham. The Toronto office will be in charge of J. Collins, late manager of the Canadian Steam Boiler Equipment Co., who is well known to the engineering fraternity in Toronto. The offices of the old firm at 380 St. James St., Montreal, have been overhauled and additional space acquired for taking care of the increased business anticipated.

MUNICIPAL

Trail, B.C.—A by-law will be submitted to the ratepayers on May 22 to raise $80,000 for extensions to the waterworks plant.

Swift Current, Sask.—The Local Government Board has given permission for the issue of $55,000 debentures for the purchase of a Diesel oil engine.

Davidson, Sask.—A by-law will be voted on by the ratepayers on May 21 to authorize an expenditure of $8,000 for the construction of a new school and $4,500 for power house improvements.

Galt, Ont.—The City Council have decided to have a vote of the electors in June on the issue of $15,000 debentures for the purchase of a drilling outfit, storage lot and buildings for the board of works, and for repairs to the three bridges over the Grand River.

Brantford, Ont.—The Brantford Township Council has instructed the township solicitor to prepare a by-law to be submitted at its next meeting, providing for the township entering into a contract with the Hydro-Electric Commission to secure electric power throughout the township.

Elmira, Ont.—The ratepayers will vote on two by-laws on May 28. The first calls for a loan of $15,000 to the Elmira Transmission and Machinery Co. The second provides for granting to the Phonola Co., of Canada, a free deed of $2,500 mortgage. The first company would increase its capacity by the addition of buildings 50 x 50 feet and 50 x 88 feet, and an extra dry kiln. The second company will begin operations at once.

Regina, Sask.—Work on the construction of the new power house at Boggy Creek will be commenced shortly and the order for the new three million gallon electrical pumping unit will be placed before the end of this month. When the new unit is installed the capacity of the plant will be nearly doubled, and it would be possible to pump seven million gallons a day if that amount were required. The estimated cost of building and unit is in the neighborhood of $10,000. Two transformers will also be installed.

TENDERS

Three Rivers, Que.—The City Council are receiving bids on four turbine pumps, each having a capacity of between 2½ and 3 million gallons per day.

St. Lambert, Que.—Tenders will be received up to May 28, for the supply and installation of a horizontal shaft centrifugal pump, electric motor and switchboard. Specifications may be obtained from H. A. Gibeau, town engineer.

Toronto, Ont.—Tenders, addressed to the chairman, Board of Control, will be received up to May 22 for two five-ton gasoline motor trucks and two three-and-a-half ton gasoline motor trucks for the Department of Street Cleaning. Forms of tender and conditions of tendering may be had on application at the office of the Street Commissioner, City Hall.

Toronto, Ont.—Tenders will be received up to Tuesday, June 5th, 1917, for the sale and removal of four horizontal return tubular boilers from the west boiler room of the City Hall, Toronto. Copy of terms and conditions may be seen, and tender form obtained, together with all information relative thereto, at the offices of the Property Department, City Hall.

Winnipeg, Man.—Tenders, addressed to the chairman, Board of Control, will be received up to May 18 for the supply and delivery, f.o.b. cars Winnipeg, freight and duty paid, to siding on Saskatchewan Avenue at the Decarie incinerator, of two horizontal water tube boilers. Plans, specifications and form of tender may be obtained at the office of the city engineer, 223 James Avenue. Lambert, Chambly Co., P.Q.

Brantford, Ont.—Tenders will be received by the secretary of the Board of Water Commissioners, until May 28, for two electrically-driven turbine pumps with capacity of 300 gallons per minute each, also electric motors and equipment. Specifications, etc., may be seen at the office of the secretary of the Board, Brantford, or at the engineer's office, Chipman & Power, Mail Building, Toronto.

CONTRACTS

Montreal, Que.—The Canadian Car & Foundry Co., has closed an order with the Canadian Government Railways for one thousand freight cars.

Agincourt, Ont.—In response to a request from the Town Council to the Hydro-Electric Commission, it is expected that they will commence extending their system of lights to Scarboro' Junction and Agincourt at an early date.

Guelph, Ont.—The Water Commissioners have awarded the following contracts for annual supplies:—Cast iron pipe, National Iron Works, Toronto; valves, Kerr Engine Co., Walkerville; brass goods, Canada Brass Co., Galt.

Ottawa, Ont.—Official announcement was made last Thursday that a contract had been granted for $5,200,000 to the estate of James Davidson, Ottawa, for the supply of spruce plank to be used in the reconstruction of the new Parliament Buildings. Tenders have also been awarded for the terra cotta fire proofing. The National Fire Proofing Co. have been given the tender for the 12-inch, 10-inch, and 9-inch terra cotta arch tile. The Sun Brick Co. was the successful tenderer for the interlocking 3-inch partition tile. The Montreal Terra Cotta Co. was given the tender for the 4-inch and 2-inch tile furring.

MARINE

Sault Ste. Marie, Ont.—The weather continues unfavorable and heavy ice is interfering with navigation. A large number of freighters have been held up.

South Vancouver, B.C.—The Board of Trade have started a movement to establish a shipbuilding plant here on the Fraser River, at the foot of Quebec Street.

Welland, Ont.—The Welland Shipbuilding Co., which was recently incorporated with a capital of $200,000, has

Aikenhead's

"Van Dorn"

Portable Electric Drills Reamers and Grinder's

THEY consume current only when working, and any lamp socket is a source of power. You will find hundreds of uses for them around your shop and they are dependable. Special fan-cooled Van Doron motor has 100% overload capacity. Van Dorn make-and-break switch acts so quickly that it practically eliminates the sticking and fusing of contacts. Phosphor bronze and ball bearing. Gears cut and hardened. All parts 100% oversize.

Do more work at less cost and they stay on the job.

You can save 20% on Tapping Jobs.

Possibly you don't think this can be done, but the **Pierce-Arrow Co.** did it, with

Wahlstrom Automatic Chucks

Aikenhead Hardware Limited, 17 Temperance Street Toronto taken over M. Beatty & Sons' shipyard and machine shop for a term of years, for the construction of steel freighters. A permit has been secured for building an additional slip on the Welland Canal.

WOODWORKING

Toronto, Ont.—Damage estimated at $1,000 was done to Phippen Brothers' sash and door factory at 746 Pape Avenue, last Thursday, by fire of unknown origin.

Port Hope, Ont.—On May 5, at Bewdley, a village at the head of Rice Lake, the sawmill with all its machinery and a large quantity of logs and lumber, were destroyed by fire. The mill was owned by ex-Mayor T. B. Chalk, of Port Hope, and the loss is partially covered by insurance.

RAILWAYS—BRIDGES

Prince Albert, Sask.—Work is being pushed forward on the laying of steel from the south branch of the Saskatchewan River into Prince Albert, giving the G.T.P. entrance to this city. It will mean a considerable shortening of the journey from this point to Winnipeg and the East ,and will open up a splendid and already well settled agricultural country.

REFRIGERATION

Brockville, Ont.—The engineers are at work installing the cold storage apparatus in the new buildings of the Laing Produce and Storage Co., which was formerly occupied by the Bowie Brewing Co. The company expects to start work immediately on the installation of a milk condensing plant, which will have a capacity of 75 tons of milk daily. It is expected that this portion of the plant will be in operation by September 1st.

INCORPORATIONS

Kamloops Sawmills Ltd., has been incorporated at Ottawa with a capital of $50,000 to operate sawmills and planing mills etc., at Kamloops, B.C. The incorporators are James C. Shields, James L. Broadfoot and William J. Baird all of Vancouver, B.C.

The National Potash Corporation, has been incorporated at Toronto with a capital of $1,500,000 to acquire and develop mineral lands and deposits. The head office is at Toronto and the incorporators are T. A. Gillen, Soloman Grand and F. C. Lee all of Toronto.

Prairie Chemical Co., Canada, Ltd., has been incorporated at Ottawa with a capital of $100,000 to manufacture chemicals of all kinds at Winnipeg, Man. The incorporators are George St. John, Van-Hallen, William C. Graham and Humphrey E. Buchan all of Winnipeg.

Eldridge Motors Co., have been incorporated at Ottawa with a capital of $40,000 to carry on business as iron founders and mechanical engineers at Calgary, Alta. The incorporators are Arthur S. Eldridge, James G. Fenton and Frank T. Kach all of Seattle, Wash.

Burroughs Adding Machine of Canada, Ltd., has been incorporated at Ottawa with a capital of $250,000 to manufacture adding, counting and writing machines at Windsor, Ont. The incorporators are A. J. Lauver, Charles G. Chapman and Eric T. Clarke all of Deroit, Mich.

CATALOGUES

Atlas Arbor Presses.—Bulletin illustrating and describing a line of presses made by the Atlas Press, Kalamazoo, Mich. A specification is included giving the principal dimensions of the various sizes of press.

The Wetmore Mechanical Laboratory Co., Toronto, have issued a new bulletin, No. 100, featuring an interesting line of small tools and gauges for munition manufacturers, including thread milling hobs, sizing taps, reamers, etc.

Band Ship Saw.—The J. A. Fay & Egan Co., Cincinnati, Ohio, are distributing copies of a new bulletin, M-19, describing No. 311 "Lightning" band ship saw, which is a new machine designed to meet present day ship-building requirements. The principal features of this band saw are dealt with fully, accompanied by illustrations showing the machine set at various angles.

Steam Pumps.—The G. H. Tod Co., Toronto, have issued a new booklet giving the practical ratings for the Tod-Attwood patent steam pumps. The tables have been carefully compiled and will be of great assistance to the prospective purchaser in selecting the correct size of pump for various classes of work. The tables show at a glance the capacity of each size of pump at different piston speeds.

Overhead Traveling Cranes. — The Brown Hoisting Machinery Co., Cleveland, Ohio, have issued a new catalogue P, describing the "Brownhoist" overhead hand-traveling cranes. The catalogue contains a full description of the single and double I beam cranes with illustrations of details and price lists giving the capacity and other particulars for various spans. Dimension diagrams for ordering are also included. Other illustrations show a number of installations in various plants, while "Brownhoist" crane-trolleys are also described and illustrated.

Transmission Ball Bearings. — The Canadian S. K. F. Co., Toronto, have issued a new and attractive catalogue dealing with S. K. F. self-aligning ball bearing hangers and pillow blocks. The construction of the bearing and its self-aligning feature are described at length, accompanied by sectional illustrations showing the general design. A variety of other matters of interest to users of ball bearings are dealt with, including such questions as the saving of lubricant, saving of power, reduction of transmission losses, belt saving, etc. The concluding pages of the catalogue contain dimensions, tables and list prices of ball bearing hangers, post hangers, and pillow blocks covering the various sizes of each type.

BOOK REVIEWS

Modern Milling, by Ernest Pull, A.M.I.M.E., is the title of a 200-page book recently published by Whittaker & Co., London, England, $1.85 net. This is a practical manual on milling operations in all its various branches, covering this section of engineering in a very thorough and comprehensive manner, and can be readily understood by anyone familiar with ordinary shop practice. A feature of this treatise is the absence of those algebraic terms that are generally so confusing to the average mechanic. The formulae that appear throughout the work, and in connection with the numerous tables, are of a character that can be easily grasped by all who understand the fundamental principles of elementary arithmetic. In addition to the detailed description of design and construction of different types of milling machines, special attachments and fixtures, practical workshop problems, with their solutions, are profusely distributed throughout the ten chapters of the book. The work is divided into sections, each chapter dealing with certain phases of milling practice, such as universal and plain milling machines, vertical, special and profiling machines, milling attachments and accessories, indexing, gear cutting, spur gears, gear cutting, spiral gears, bevel and worm gears, milling operations, milling cutters and arbors, speeds and feeds With 188 illustrations and numerous tables, this work should prove a very valuable reference to those associated with modern milling and general machine shop practice.

NEW RAILWAY LINE ACROSS EUROPE

By Mark Meredith.

M. HERRIOT, Mayor of Lyons and Senator of the Rhone, has put before the French public a scheme for the construction of a new transcontinental line which will link France to Russia, via Italy, instead of via Berlin. Before the war, there was only one great overland route: Paris-Berlin-Warsaw-Moscow or Petrograd, with the Berlin-Koenigsberg alternative. As Italians have pointed out recently, it will henceforth be possible, without the least difficulty, to create a direct route between France and Russia which will be quite independent of Germany. It would run from Bordeaux, through Lyons, Turin, Milan, Trieste, Belgrade, and Bucharest, to Odessa. Such a railway route would not only provide a substitute for that of Berlin-Petrograd, but also to that of Bagdad, for it would be easy to send a branch line to Constantinople.

This new transcontinental line, which the Italians have termed that of the Forty-fifth parallel, and which would extend, if calculations are exact, over 3,600 kilometers (instead of 6,200 kilometers by the sea route), would permit of the rapid transport of passengers, mail, parcel post, valuable and perishable goods. The famous Gothard convention, which will have to be considered at the time of the signing of the treaty of peace would no longer be harmful to the interests of the Entente Powers. France and Italy would reap immense benefits from such a scheme, which would be the great economic event of the alliance which owes its existence to the war. Germany would lose her power of control, for she would find herself enveloped on the north by a maritime route between France and Russia and on the south by the new overland route.

The political advantages of such a scheme need hardly be pointed out. The entire situation in the Balkans would be improved by the possibility of easy and uninterrupted relations. The future of Serbia and Rumania would be assured, and they would be freed from their economic dependence on the Central Empires. The French and Italian Governments are very favorable to the scheme. Southern Russia is on the eve of immense development, which necessitates due preparation and provision.

This line would be the true Metropolitan of Europe, but in order to be ready for its inauguration at the proper time, it is essential that the necessary reports on the work to be done should be made now. The administration of such a line, the tariffs, and all necessary details, should be gone into and fixed. Circumstances are in our favor. They have brought Great Britain, France, Italy, Serbia, Rumania, and Russia together, and the opportunity thus provided should not be lost.

Oxy-Acetylene Welding in the Machine Shop and Tool Room

Staff Article

Autogenous welding, on account of its adaptability to general engineering practice, has become an indispensable factor in metal manufacturing industry; the field, however, has been somewhat restricted, owing largely to the lack, on the part of many blow-pipe operators, of the fundamental knowledge required for the proper manipulation of the work upon which they are engaged. The subject matter herewith shows to what extent this process can be adapted to the requirements of general machine shop and tool-room construction and repairs.

DURING the last few years considerable progress has been made in the autogenous welding of metals by the oxy-acetylene process, and recently, engineers and manufacturers have realized its undoubted possibilities in lowering costs of production. As an adjunct to the tool room, the saving effected by this process has been particularly noticeable. In the construction of a jig or fixture, one has generally the choice of two methods: to prepare a pattern from which a casting is made, or to build up from stock material or forgings; each having its own advantages. With the first method welding is not required, unless it is to reclaim a casting that has been spoiled through error, or developed blow holes in machining, when welding would affect the repairs rapidly and cheaply.

It is in the construction of jigs of the built-up type that oxy-acetylene welding will be found of the greatest benefit. The

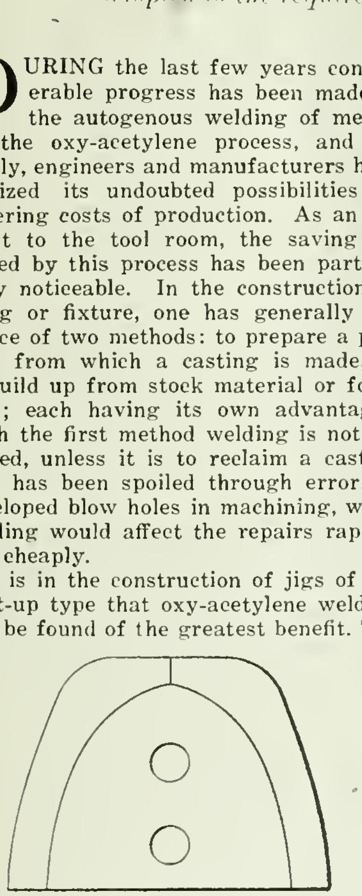

FIG. 1. STELLITE-FACED CUTTER.

majority of them can be built up from old pieces of material, while the use of intricate forgings is done away with. In such cases, the alternative would be to drill, screw down and dowel the parts together, a method which is never very satisfactory, particularly if the jig is subjected to much vibration, as the screws always have a tendency to work loose. Parts can also be welded quickly together, that, from their shape, could not be screwed with any security. Bosses, ribs, webs, etc., can be built up direct from the feed rod, allowing material of lighter section to be used, and dispensing with a great deal of machining. Snap and other gauges of the fixed limit type can be reclaimed when worn out, at a very trifling cost, by adding new metal to the jaws and regrinding to the proper size. This is one instance only of the innumerable ways that the oxy-acetylene plant handles not only efficiently and quickly, but very cheaply, the numberless jobs which come into the tool room from day to day.

Case Hardening

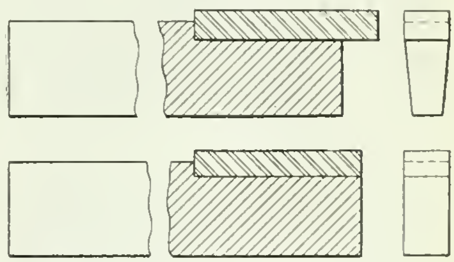
Ordinary case hardening is generally obtained by carbonizing the outside shell of mild steel pieces, thus transforming the exterior skin to a high carbon steel, giving hardness. Such result is obtained by putting the castings or other pieces, in contact with incandescent carbonaceous substances, so that the metal absorbs the carbon. The characteristics of a case hardened piece are shown by the thickness of the skin transformed in the steel, and as the percentage in carbon decreases from the outside to the inside, a case hardening well done should affect a sufficient thickness of metal treated, and the percentage of carbon should decrease gradually from the outside to the inside and should not be constituted by a film of hard metal without a transitory period of the original metal. Case hardening done by means of an ordinary mixture made of charcoal, carbonate of baryum, or organic matter, gives layers very resisting which do not split even when showing much hardness, because the decrease of carbon is regular; but case hardening made by rubbing special powder (generally containing ferro cyanide of potassium), on small parts which are red hot, gives a very hard skin but not very thick, which is liable to flake away during tempering.

The use of the oxy-acetylene blow-pipe for case hardening permits the obtaining at will, according to the handling of the blow-pipe, either of the above described results; that is to say, a deep layer with gradually decreasing percentage of carbon, or a thin, very hard layer. To obtain quick and deep case hardening, the blow-pipe should be well regulated and the end of the inside tip of the flame should be kept at a distance of about one inch of the metal to be treated; when the desired temperature is attained, a slight excess of acetylene should be given. The flame contains an excess of free carbon which is very readily absorbed by the metal, which is being kept hot by the heat of the flame. To obtain a thin and very hard layer, the inside tip of the flame should be kept close to the part being treated, care being taken at all times not to burn the metal.

The following results have been obtained from experiment, care being taken to keep the pieces at a cherry red heat while being treated: (a) With the white inside cone of the flame kept for two minutes, at ⅝ inch off the metal, open hearth steel has given a high carbon layer of metal ½ m.m. deep, and the surface of the metal showed a percentage above two per cent., consequently giving a case hardening similar to chemical powder. (b) Holding the inside flame of a blow-pipe, with an excess of acetylene, 1¼ in. from the metal during a period of ten minutes, the case hardening affected a thickness of three mm. without the exterior skin, showing a richness of carbon superior to 0.85 per cent. of carbon. Consequently, case hardening by the blow-pipe gives very interesting results; an application of 2 minutes is sufficient to give to a surface a hardness comparable to the treatment of the most active hardening powder, while by lengthening the application to from 5 to 10 minutes, case hardening can be obtained showing a depth treated of 2 or 3 millimeters, of a very regular character, and with a gradually decreasing percentage of carbon, the highest percentage not being high enough to provoke flake during tempering.

Surface Hardening

The use of the blow-pipe for case hardening should not be confused with its use for surface hardening. In the first



FIGS. 2 AND 3. OXY-ACETYLENE AND ELECTRICALLY WELDED TOOLS.

case, the excess of carbon purposely produced in the flame, changes the chemical composition of the steel being treated, while kept hot with the blow-pipe; while in the second case of surface hardening, only the heating power of the blow-pipe is used as a convenient way to apply heat to the surface of a piece of steel, while the rest is kept cool with running water or other devices. This oxy-acetylene hardening process is a cheap and rapid method of hardening; it is applicable to such purposes as the hardening of the surface of gear teeth, castellated shafts and bores, template holes, and in general to the localized hardening of any small areas upon large articles, particularly where the ordinary hardening process would cause distortion that would be difficult to remove afterwards by grinding.

Surface Hardening of High Tensile Steels

A system of surface hardening which can be applied to local parts of any casting or forging of high tensile steel, without involving distortion and without destroying the effects of the usual heat treatment to which the whole casting or forging may have been subjected, has been perfected. The equipment usually supplied for oxy-acetylene welding is used, four sizes of burners meeting all requirements. The work to be hardened locally, is placed on a tank of water with adjustable overflow, so that the water level can be regulated, as while the portion of the surface being hardened is instantly heated to the required temperature, the whole of the remainder of the article is kept as cool as possible by being immersed in water. Should the immersion method not be possible, the part not being hardened must be kept cool by water flowing over the surface. The burner is held so that the outer portions of the flame flow in the direction along which the burner is travelling, and the portion of the steel heated should be cooled, when intense hardness is desired, by arranging that cooling water shall flow as close as possible to the traveling burner, but not so close as to disturb the flame, because that is not only liable to put it out but prevents rapid heating, and causes irregular hardening. The flame required should be of the highest possible temperature and burn close to, or even under water, this high temperature being obtained by adjusting the flame as for welding, and then increasing the pressure of the oxygen so that the flame changes color and appearance from a white cone to a bluish streaked tongue, when observed through smoked glasses. In this method the essential to success is the speed of the heating; as the flame passes along, the surface is instantly cooled by the cold body of the remainder of the forging or casting, leaving it at the maximum hardness of which the steel is capable when heated and quenched in cold water.

To obtain a thin but intensely hard surface, the part to be hardened should be just below the surface of the water, the impinging flame blowing the film of water away. The normal depth of hardening is about 1/16 in., but a greater depth, up to ⅛ or 3/16 in., can be obtained by slightly prolonging the heating. A slight wavy or rotary movement should be given to the flame to avoid burning the surface of the steel. Contrary to what might have been expected, even with the hardest steels, there is no tendency of the hardened surface to crack or flake away from the unhardened portion. In a number of cases made for examination, not a single instance shows any parting between the hardened and the unhardened portions. While the process in the above case is applied only to high tensile steels, it is of interest to engineers to note that cast iron and black heart malleable iron castings can also be given a glass hard surface by hardening in this manner with the oxy-tcetylene process.

Stellite and the Field Opened to It by Oxy-Acetylene

This wonderful high speed tool metal (which the manufacturers claim is "not a steel but its master," and which will cut out 25 to 300 per cent. faster than the best high speed steel, is so hard that it cannot be forged and will cut as well when red hot as when cold), had one very serious disadvantage, which very considerably retarded its more general adoption; this disadvantage was its brittleness, which generally prevented stellite being used in the solid tool form, but necessitated its use in a tool holder. Apart from the general objections to tool holders that are well known, this method of using stellite was only partially successful, as even with the best designed tool holders, it was impossible to support the metal right up to the cutting edge, with the result that any slight jar, or an extra hard spot encountered, the stellite would break away through want of sufficient supporting. The tool holder was supplanted to a certain extent by using electric welded tipped tools, but as is subsequently pointed out, electric welding is limited to certain straight work of predetermined section, and consequently this did not overcome the difficulty to any great extent.

Stellite can, however, be worked with perfect ease, with no limitation as to size or shape, under the oxy-acetylene blowpipe. An oyx-acetylene stellite built tool gives an ideal tool, presenting the extremely hard cutting qualities of the

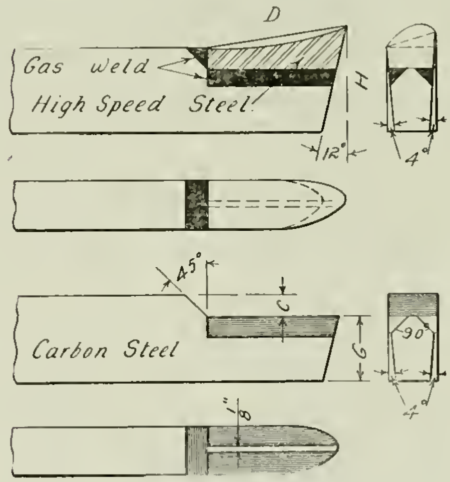


FIG. 4. PREPARING TOOLS FOR WELDING.

stellite, with the absence of tempering and minimum of grinding; supported homogeneously on a low grade steel shank which will withstand the severest shocks and has the same hardening adaptability and heat radiating features of a solid tool. The method of tipping is different to the welding of high speed steel, in this respect, that no previously prepared tip is needed, but the stellite is used in the form of a filling in rod and fused direct on to the shank, which has been pre-heated in the ordinary way; ⅜ in. stellite rod has been found to give the best results. This method of facing has the particular advantage that any form or shape of tool or cutter, can have the cutting edge lined with stellite. Fig. 1 shows a very interesting example of this work. The cutter in question was an ordinary rough cutter for boring 6 in. high explosive shells; it was machined on the cutting edges ¼ in. wide and 1/16 in. deep, and then built up with stellite, ground and put into service, and up to the time of writing it had bored 119 shells without any further grinding, and was still in good condition. A stellite tipped rough turning tool turned sixty shells with only one grinding of the tool. Small ordinary circular tools for facing shell base plates, tipped with stellite, gave equally good results, and in no case of the tool under test did the stellite come away from the shank of the holder, when fused on by the oxy-acetylene process.

Welding High Speed Steel

It is perhaps in the field of welding high speed steel tips to carbon steel shanks that the greatest saving can be effected; with the present price of high speed steel at $3 per pound, a tool for ordinary heavy work of 1½ inch section, would weigh approximately 9 pounds, and would cost, without any labor charges for forging, etc., about $27. The relative cost of a tipped tool using ½ pound of high speed steel at $1.50, and 8½ pounds of carbon steel shank at $1.02 (12 cents per pound), giving a total cost of $2.52. It will be found in actual practice that the cost given for the tipped tool is excessive, as the high speed tips are made up from short pieces of steel, broken cutters, etc., which have only a market value of scrap steel, and the shanks, except in the case of very large users, are pieces reclaimed from the scrap pile.

There are three methods in general use of welding these tips: (a) by means of welding flux; (b) by the electric process, and (c) by the oxy-acetylene process. The first method has been adopted in a number of shops with varying degrees of success, due largely to the fact that each engineer has his own ideas as to the ingredients of the flux. A patent has, however, recently been granted covering a specific flux; but irrespective of the kind of flux used, its field of operation is strictly limited. In the second method, that of electric welding, the limitations refer more particularly to the capital outlay necessary, which prevents the system being adopted in any but large plants where welding work is continuous. Also, the preparation of the tools in electric welding has to be carefully thought out, for it is essential in making a butt weld that the cross sectional area of the two pieces be equal. This entails considerable loss of time and material in grinding the necessary clearance. To illustrate: Fig. 2 shows a tool that has the necessary clearance for use, but which it would be practically impossible to weld electrically, while Fig. 3 shows one that is correct for electrical welding, but would require considerable grinding for use. These welding limitations do not apply to either flux or oxy-acetylene welding.

It must also be remembered that with the electric process, the heat is bound to be concentrated upon the point to be welded, and no local annealing of the metal around the weld is possible, as is the case when gases are employed. This question of local annealing is one of vital importance. There are, of course, certain classes of work for which electric welding is the most suitable method to employ, but in general, a gas welding plant is better and more adapted to general workshop use.

The third method, oxy-acetylene welding, has no limitations outside the skill of the operator. Tips can be welded on irrespective of their size or shape; broken cutters can be welded together, or additional metal can be used to fill up the gaps, etc. In a perfect weld, the union of the two pieces should present the same chemical composition and physical characteristics as the jointed surfaces. Under these conditions the entire joint possesses a homogeneous structure and no variation in the mechanical properties should be disclosed in the different portions. This is where the oxy-acetylene process is distinctly in advance of any other at present in general use. It uses as a filler, metal of exactly the same chemical composition as the parts to be welded, and when combined with this is an advantage of welding any shape or size of tool with equal ease, it can be more fully appreciated why a gas plant for general workshop use, is better and more adaptable.

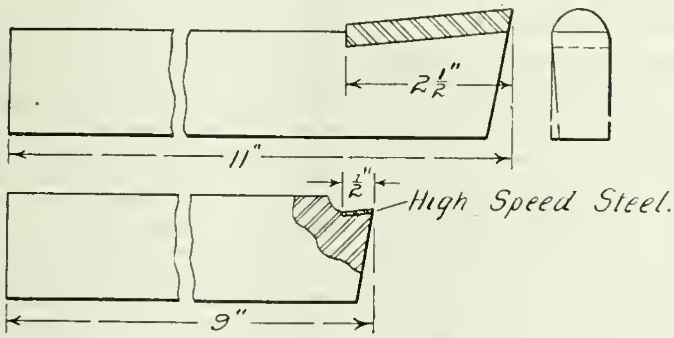

FIG. 5. LATHE TOOL WITH WELDED TIP.

Preparing Tools

The general practice adopted for repairing or tipping lathe, planer, or other metal cutting tools is to bevel the shank as shown in Fig. 4. The lower view shows the shank prepared for welding, and the upper view the appearance of the tool after the weld has been made. This can be done most economically by the blacksmith when forging; the tips should also be cut by the smith to the approximate shape, to save grinding as much as possible, and also with a view to utilizing all odd and small pieces of the more expensive grade of steel.

Pre-heating

With the object of avoiding as much as possible, the interior oxidisation of high carbon steels, it is good practice after the shank and tip have been prepared, to heat before welding, and to weld with a powerful blowpipe, reducing the time of welding to the minimum, thus obtaining a more homogeneous weld. Pre-heating should be arrested at a red heat, which permits of a regular execution of the weld by avoiding local overheating, the interior oxidisation being less intense and the work more rapidly performed. At all times, it is advisable to reduce as much as possible, the interval between the commencement and completion of the fusion.

Welding

The shank and tip having been pre-heated, the former should be placed on the welding bench and the steel tip placed in position and tacked; that is, attached to the shank with a small piece from the welding rod. The tool should then be turned on each side successively and welded in on the space left by the beveling, to the uniform surface of the tool, care being exercised at all times to avoid playing the flame too long in the one spot, as this has a tendency to burn the metal.

Filling Material

The welding material used for welding high speed steels, to carbon steel shanks, may be either Swedish iron or vanadium steel rods, the latter giving the best results of the two. In special cases, such as welding a broken cutter or filling up a gap on the cutting edge of a boring cutter or drill, steel of the same quality as the defective tool should be used.

Heat Treatment

A point that many manufacturers overlook, is the physical properties of high speed steel and ordinary tool steel; these are so different that strains are set up by welding, unless the pieces are heat treated before they have a chance to cool down from the welding heat. Therefore, to obtain the greatest efficiency, a furnace should be near the welding bench, where heat treatment can be accomplished; in general practice, where the life of the tool is of short duration, the tool is not treated in the furnace, but buried in lime or asbestos as soon as welded.

Examples of Oxy-Acetylene Welded Tools

Straight tipped tools are used in very large numbers and actual working experience has shown that they are equal in every respect to solid tools, and when properly welded and hardened, the tips wear to the last small piece. Fig. 5 shows one of these tools, (a) shows the tool used for rough turning, tipped ready for use, and (b) shows the condition of the same tool when it came out of the machine shop for retipping. These tools are comparatively easy to weld, and therefore will not be of so much interest as the following examples, which demonstrate that the oxy-acetylene process accupies a field entirely its own, doing work that cannot be done by any of the other welding processes.

Circular tools are used for various kinds of profile work, and their delicate construction often results in cracking or breaking when being hardened or defects may develop after being put into service. In Fig. 6 are shown several of these tools that have been effectively reclaimed after breaking. They are 1⅛ in. outside dia., 4 ins. long, with a 9/16 in. hole drilled through the centre; the sizes given are of course not standard, as they have to conform to the particulars of the tool box in which they are being held. (A) shows a tool which was broken in three parts, evidently due to over heating or hardening. It was welded up, using high speed steel as a filler, afterwards heat treated and rehardened, and then put into service; after three days of continuous work (day and night shift), during which time it was reground as necessary, it showed no defects at all and could not be distinguished from a new solid tool. At (B) is shown the same type of tool beveled at the edges on the grinding wheel ready for welding. At (C) is shown one with a chip broken out of the side, ready for filling up, and (D) one that was worn too short to be properly held in the tool post, being welded on to a carbon steel shank of exactly the same dimensions and construction.

Every engineer knows the difficulty and expense in keeping flat boring cutters up to standard dimensions. They are generally made in two sizes, finishing and roughing, the general practice being to make them to the finished size, and when too small for this purpose regrind them for the roughing operation. It is also known that the life of these cutters is very short and erratic; sometimes they will strike a hard spot in the steel being worked, and burn, leaving a gap that very often destroys the cutter altogether, for by the time the gap is ground out it is too small for a rougher. In other cases the cutter cracks through or a piece will break off, thus destroying the tool unless some satisfactory means can be used for reclaiming the same. These cutters can, of course, be machined down to form smaller cutters for other work, but the initial cost of the original machining has been lost, and most manufacturers will be able to estimate what this loss represents in their own business. In Fig. 7 is shown several flat

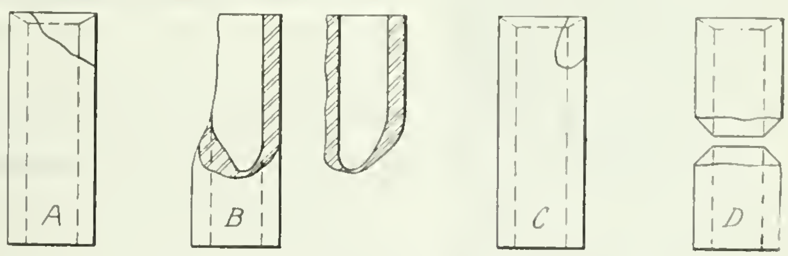

FIG. 6. PROFILING CUTTERS REPAIRED.

boring cutters that have been successfully reclaimed from the scrap pile; (A) illustrates a cutter that had a gap on one of the cuting edges, as indicated by the dotted line, which was filled in with steel of the same grade as that of the cutter with excellent results, making the cutter as good as new. At (B) is shown a similar cutter that was broken, with the pieces ready for welding, and (C) shows another cutter where the broken part was lost. This cutter was successfully built up to its original size with added steel of the same grade.

The size or shape of cutter or tool, or the nature of the break, makes no difference whatever to the process, for, as stated previously, the only limitation is the skill of the operator. Examples like the foregoing could be given in indefinite numbers, but each one would only be a repetition of the fact that an oxy-acetylene plant in the tool room, is not a luxury but a stern necessity.

Operation

Despite the fact that welding work generally is now on a more scientific basis than formerly, along with the ease with which an oxy-acetylene plant can be handled, so much so, that sufficient knowledge may be acquired in one or two days to enable a man to turn out useful and profitable work, the successful attainment of high skill in welding is still a difficult matter and considerable practice and concentration is essential to become perfect in the proper manipulation of the blowpipe. It should be borne in mind that there must necessarily be different grades of welding operators in exactly the same sense as there are different grades of tool makers, machinists, etc., as perfection is more a human than a mechanical factor. Indeed the ease of handling the oxy-acetylene torch has ben one of the ever recurring difficulties that manufacturers of the apparatus have had to contend with. In the ordinary course of tool room work, when a difficult or intricate tool or jig has to be made, the foreman generally picks out one of the best men to do the job, and in case of failure, the cause is thoroughly investigated and the blame apportioned accordingly; but with the oxv-acetylene process, sentence is invariably passed without any investigation, and the general verdict is, "It is no good for that kind of work." This summary treatment is due, in a great measure, to the lack of knowledge of welding principles, not only on the part of operators, but also on the part of their foreman.

It is not to be understood from these remarks that a number of welding operators are necessary, but in handling work of a specific nature, a man should be trained who understands the nature of the material he has to handle in tool work, cutters, etc., such as described in this article; a good tool blacksmith or a man skilled in tool tempering is the ideal material from which to obtain the best results.

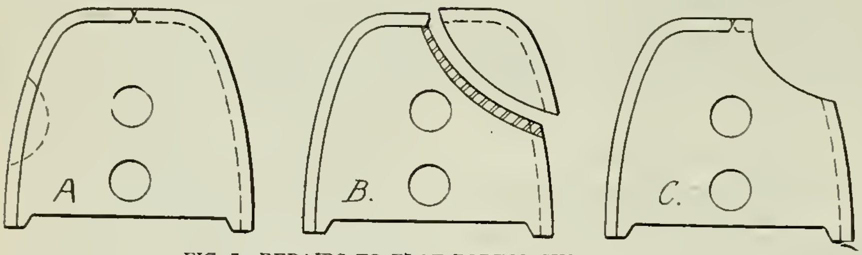

FIG. 7. REPAIRS TO FLAT BORING CUTTERS.

SMOKE PREVENTION

THERE has been considerable agitation against smoke emission, and in all important cities smoke-prevention departments have been formed and laws made againts smoke emission. The objections to smoke, as stated, are "public nuisance" and "fuel loss." The methods employed by smoke departments are effective in preventing the first, but the value of some of them as to the second is very doubtful. It is well known that the chief loss in a boiler plant is due to excess air (low CO_2), and not due to incomplete combustion, of which the result might be smoke.

To prevent smoke effectively, it is necessary to centre attention on the quantity of air used to burn the coal and keeping it down to a minimum, proper furnace temperature and possibilities for well mixing the combustible gases and the air. At present (with exceptions), most attention is paid to smoke and smoke alone, without paying the attention to excess air loss that it deserves. As a result many plants are wasting more fuel since operating smokelessly than before, because of using more excess air.

Smoke-prevention departments could greatly aid in preventing national fuel waste and some of them are doing so, but where they are not it can be laid to:—

(a) Political influence and interference.

(b) Lack of funds to employ expert inspectors.

(c) Employment of methods having no scientific basis and lack of effort to educate the engineer and firemen, while at the same time more force is employed than is good for the cause.

(d) Lack of confidence on the part of the power plant owner because of all of the above.

Exceedingly few firemen, not even 3 per cent., know the simplest rudiments of combustion. Many who are considered good firemen persist in operating their furnaces so that at least 20 per cent. of the fuel is wasted; at the same time claiming that it is the better and proper way. To overcome such conditions they must be educated.

It would be a great help if more of the simplest literature could be obtained, describing the economical process of firing, and this written in an interesting way. It is not meant that there is no such literature, for an immense amount of good has been done by different journals of this character, but the man who needs it most does not get it, and it would pay to bring it to him.

The U. S. Bureau of Mines would increase its usefulness by including in its excellent editions on fuel technology from time to time, bulletins of a thoroughly practical nature especially adapted to the average boiler-room man. These bulletins should be written by men who know the fireman and who have been through the mill themselves. After such bulletins are ready they should not be kept until those who need them write for them, but they should be given a forced circulation with the aid of boiler-insurance companies, smoke-inspection departments, business men's leagues, etc.

POWER PLANT OPERATION AND MANAGEMENT

TO obtain the greatest efficiency possible in a power plant is not only a matter of design, but a good deal a matter of proper operation and management. Most power plants could make large savings in this way, and there are exceptionally few where some improvements could not be made without spending a dollar for new equipment. To obtain full benefit from the equipment on hand, the men operating it must be made more efficient, and this can be done by education, strict supervision, pay according to merits (bonus system), competition and advancement, welfare.

Education, while the most important, is also the most neglected factor in economic operation of a power plant. This is especially true in the boiler room where the waste is greatest. Skilled labor should be employed. Ordinarily, anyone is hired who will work for low wages and maintain the steam pressure. Every boiler room should have a man with authority to give orders and with sufficient personality to have his orders respected. This man should predetermine by the proper use of various instruments, the most economical ways of burning coal and instruct the firemen as to the best methods, and then insist that these methods be carried out.

Jointly with extending the license laws and making examinations more strict, opportunity should be offered to men intending to become operating engineers to acquire the necessary knowledge. While the practical part can be learned in the power plant directly, the fundamentals of theory which are all important to the up-to-date operating engineer are difficult to obtain properly. Co-operation of educational institutions is needed by the forming of classes at the various universities and other schools to give courses on economic operation of power plants. Instruction should be given by correspondence to those unable to attend in person.

Suggestions on the Standardization of Machine Tools*

By Carl G. Barth

The article deals in turn with the subjects of standardization of the machine equipment of a shop as a whole, standard speed series, standard feed series, the power of machine tools, tool posts for lathes, lathe centers, T-slots, lathe centres, drill-press and milling-machine sockets. The object is to encourage machine tool builders to adopt certain standards.

WHILE engineers and manufacturers are realizing more and more the desirability—yes, necessity, for standardizing, not only their own individual methods and product, but also to some extent the methods and product of each group engaged in the same line of manufacture; and while encouraging progress is being made by associations of manufacturers of such modern products as automobiles, electric motors and lighting apparatus, and no doubt by other associations of which the writer has no personal knowledge, little, if anything, has been accomplished by the machine-tool builders of this country.

Objection to Standards

Before proceeding to any definite recommendations, it will be well to consider the objection so often raised to the adoption of standards of any kind—that standardization blocks the way for further development and improvement. If this were unqualifiedly true, standardization would almost be a crime; but if we adopt a standard merely as representative of the best a trade or profession knows of at any one time, with the understanding that as soon as a decided improvement is brought out, a new standard will be adopted to parallel temporarily and eventually replace the former standard, the danger of stagnation will be obviated.

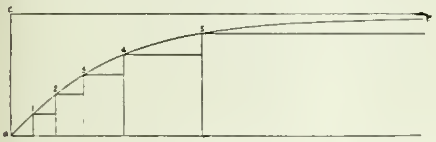

FIG. 1. CONTINUOUS vs. STEP BY STEP DEVELOPMENT.

Perhaps my idea will be understood more readily by reference to Fig. 1, in which the smooth curve ab tending towards the asymptote cd represents a gradual development with immediate adoption of improvements in any line towards an eventual highest possible attainment, and the broken line whose corners 1, 2, 3, 4 and 5 lie in this curve the only occasional adoption of such improvements; when these have attained enough importance to make it worth while to change from one temporary standard to a new one, both standards are in use during the period of change. Such a period will, to be sure, seem exceedingly inconvenient after we have once tasted of the fruits that the use of standards bring forth, but it will be as nothing compared with the troubles and expense of dealing with a lot of unstandardized equipment all the time. "Where ignorance is bliss, 'tis folly to be wise," surely does not hold good in these matters.

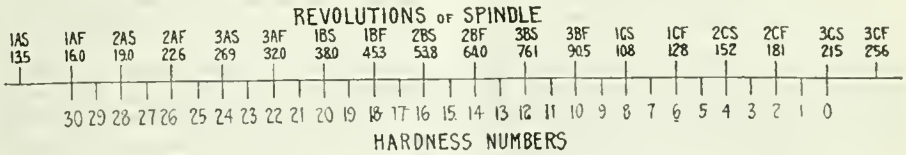

FIG. 3. LOGARITHMIC PLOT OF REVOLUTIONS OF SPINDLE AGAINST HARDNESS NUMBERS.

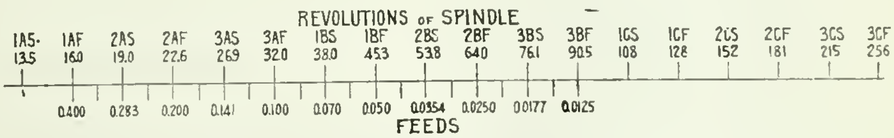

FIG. 4. LOGARITHMIC PLOT OF REVOLUTIONS OF SPINDLE AGAINST FEEDS.

Standardization of Machine Shop Equipment as a Whole

By this illustration I have particularly in mind the exceedingly one-sided manner in which most users of machine tools try to get the most up-to-date and best (if those users are not the kind that

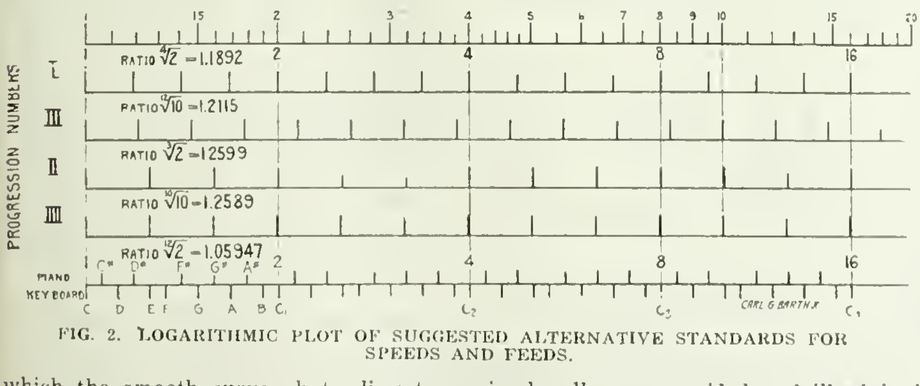

FIG. 2. LOGARITHMIC PLOT OF SUGGESTED ALTERNATIVE STANDARDS FOR SPEEDS AND FEEDS.

simply allow an unaided and ill-advised purchasing agent to buy on price alone), whenever they have to add to their equipment, regardless of whether or not the most up-to-date machine of a kind fits in with older equipment that will not be sufficiently behindhand to be discarded and replaced for years to come.

During many years of experience, the writer has gradually been forced to see an enormous advantage in also standardizing the machine equipment as a whole, aside from the standardization of the mathematical and certain constructive features of each machine. Wherever possible his effort is to have only the very same make of machines in a certain productive group, and in the expansion of such a group to add machines of exactly the same design, even to the extent of having a manufacturer furnish what is no longer his most recent product—only, however, if this or some other manufacturer's most recent product is not a sufficient improvement over the old to warrant the introduction of a new machine as a new standard for the work to be done, with the intention that this type will eventually crowd out and replace the older type.

As an encouraging example of this, the writer recently had the satisfaction of seeing a newly-acquired client award the contract for a dozen large milling machines to one bidder, while the original intention had been to divide the order between two or more bidders, in order to obtain quicker deliveries as the paramount consideration.

Standard Speed Series

As in the present state of the science and the art of cutting metals, it is, on the average, impossible to determine the most economical or suitable speed and feed at which to run a machine for any set of conditions closer than a certain percentage. It is by this time universally accepted by those who have a right to an opinion in the matter that the available speeds of a machine should be in a geometrical progression. A discussion of this will not be undertaken by the writer unless provoked by some one else, though even at a recent date the futile attempts of some designers to arrange a series of

*From a paper before the annual meeting of the American Society of Mechanical Engineers in New York City.

speeds in a geometrical progression are conspicuous. The reason for this is that a number of our machine-tool builders, while strong men of inventive genius or business ability who have worked their way to the front from the shop, have never acquired sufficient theoretical engineering training to appreciate the mathematical problems involved, fundamentally simple though they are, and usually employ draftsmen and designers equally deficient along their line, many of whom, on the other hand, display ingenuity in their work that is little short of marvellous.

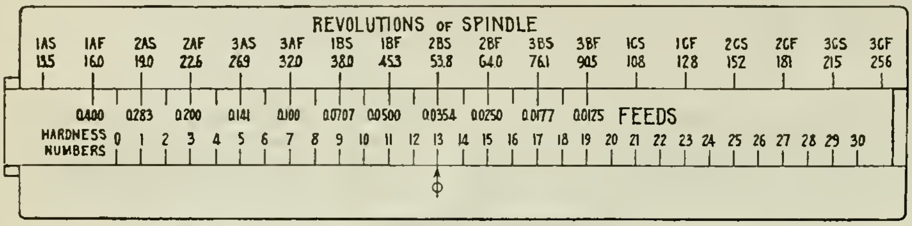

FIG. 5. SLIDE RULE DEVELOPED FROM LOGARITHMIC PLOTS OF FIGS. 3 AND 4.

It being first agreed that a geometrical series of speeds should be provided for any one machine, the writer's idea is that a universal speed series should be adopted by all machine-tool builders for all machines, such as lathes, boring mills, milling machines, drill presses, etc., that are provided with a spindle for either the work or the cutting tool, and which, except in the case of certain single-purpose machines not included in this discussion, may be rotated at different speeds; for our present knowledge does not warrant us in asserting or assuming that a progression of speeds for one kind of these machines should have a lesser or a greater constant ratio than for any other kind; and, evidently, if there is no reason for making them different, there is every reason for making them just alike. The question then becomes, what should be the constant ratio of such a universal geometrical progression of speeds?

As far back as 1888 the writer designed for William Sellers & Co., Inc., of Philadelphia, a large lathe which had 30 speeds in a practically perfect geometrical progression, with a ratio of a little over 1.15, obtained by a correct relation between a 5-step cone, two back-gear reductions and two forward speeds of the countershaft. Again, in 1892, he designed another with 36 speeds which had a practically constant ratio of but little over 1.14, obtained by a 6-step cone, two back-gear reductions and two forward speeds of the countershaft.

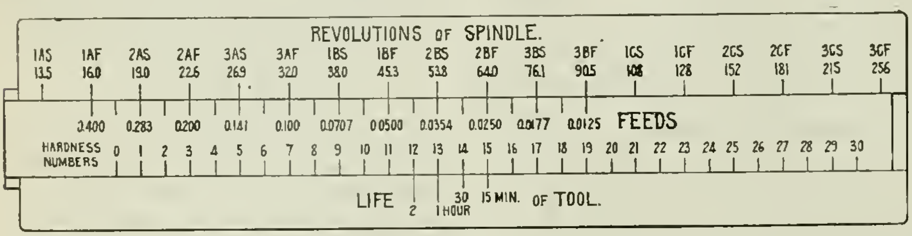

FIG. 6. SLIDE RULE DEVELOPED FROM FIG. 5 BY ADDITION OF LIFE RELATION OF TOOL.

These designs, only the latter of which was actually built, prove that this company was able long ago to appreciate the theoretical value of close speed regulation, though at that time the prevailing style of shop management, or rather lack of shop management, throughout the country was such that this knowledge was undoubtedly of no practical value to the operator, even in the shop of that company. In fact, when the writer finally got some real ideas about such matters during his first two years of association and co-operation with Mr. Taylor at the works of the Bethlehem Steel Co., immediately after Mr. Taylor and Mr. White had made the discovery of the high heat treatment of tungsten steels, the writer realized that he had overreached himself in those two lathes. Therefore, in designing some special lathes for the Bethlehem Steel Co. for the better utilization of the new high-speed tools, he adopted 1.2 as a more rational ideal, and he has never since found any reason for deviating materially from this ratio; though it was several years later before he recognized the desirability of an absolutely constant ratio, not only for all lathes, but, as referred to above, for all machine tools with a revolving spindle.

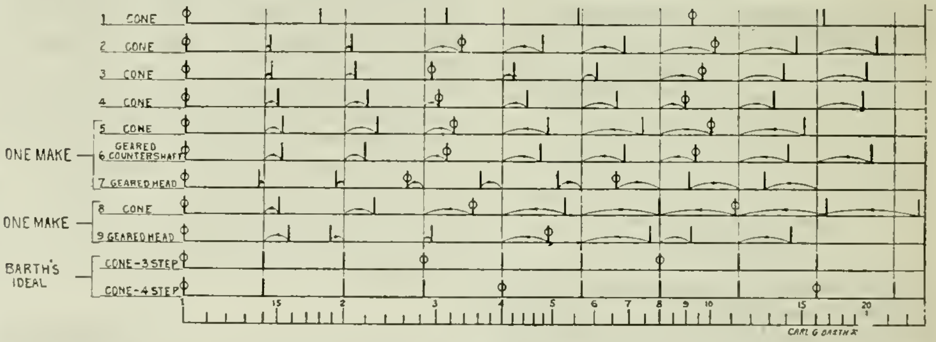

FIG. 7. LOGARITHMIC PLOT OF SINGLE COUNTERSHAFT SPEED SERIES OF NINE 16-INCH LATHES SUBMITTED BY VARIOUS MANUFACTURERS IN FEBRUARY, 1914.

However, if we construct a geometric progression with this simple ratio 1.2, and beginning with 1, all subsequent terms of this will naturally be found to be anything but simple numbers, thus: 1, 1.2, 1.44, 1.728, 2.074, 2.488, 2.986, 3.583, 4.300, 5.160, 6.192, 7.430, 8.916, 10.70, 12.84, 15.41, 18.49, 22.19, 26.62, 31.95, 38.34, 46.00, etc.

Progression—I.

In reality, therefore, we will have a simpler progression by slightly modifying this ratio 1.2 such that the fifth term becomes 2 instead of $1.2^4 = 2.074$, for then the whole progression becomes 1, 2¼, 2½, 2¾, 2, 2.2¼, 2.2½, 2.2¾, 4, 4.2¼, 4.2½, 4.2¾, 8, etc., or 1, 1.892, 1.4142, 1.6818, 2, 2.3784, 2.8284, 3.3636, 4, 4.7568, 5.6569, 6.7272, 8, etc., with every fourth term a power of 2, the simplest of all numbers except unity itself. The above fractions, as also in subsequent progressions, denote the power which the integer is raised.

This is, to the writer, an exceedingly attractive progression, and represents his ideal for some six years past, particularly as he cannot help comparing the revolutions of a rotating spindle with the vibrations of a musical string. In a piano, for instance, the number of vibrations of the strings also forms a geometrical progression with 2 as a constantly recurring factor, namely, as the ratio between strings that sound notes on octave apart. Because of this similarity, the writer, for lack of a better term, has named a series of speeds conforming to the above geometrical progression a chromatic speed series, though the term chromatic in connection with a musical scale has reference to the geometrical progression involved, rather than to the ratio 2 of the number of vibrations of two notes in an octave.

It may be, however, that the majority of machine-tool builders will consider the ratio $\sqrt[4]{2} = 1.1892$ unnecessarily small, and would deem a somewhat large ratio preferable in order to obtain a larger final ratio between the slowest and the fastest speeds of a machine which, for one consideration or other, may have to be arranged with a rather limited total number of speeds, as, for instance, a lathe with a single back-gear reduction, or a small drill press or milling machine with no back-gear reduction at all.

Progression—II.

The writer's answer is that he has had in mind also, as a possibly more generally acceptable progression, one with the constant ratio $\sqrt[3]{2} = 1.2599$; that is, 1, 2 1-3, 2 2-3, 2, 2.2 1-3, 2.2 2-3, 4, 4.2 1-3, 4.2 2-3, 8, etc., or 1, 1.2599, 1.5874, 2, 2.5198, 3.1748, 4, 5.0397, 6.3496, 8, etc., which is as much entitled to the name chromatic as is progression I. In fact, in recently rebuilding eighteen vertical single-spindle drill presses for a client company, he made the speeds of these presses conform to this progression, in connection with a fixed gear reduction of

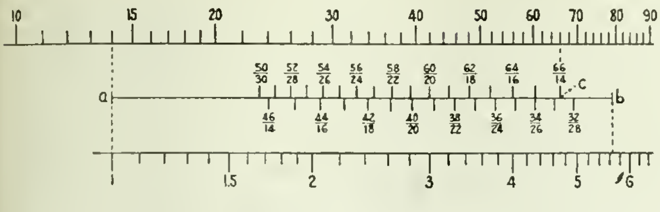

FIG. 8. SIMPLE LOGARITHMIC SCALE METHOD FOR GETTING THE CLOSEST POSSIBLE APPROXIMATION TO A GIVEN RATIO WHEN TWO SETS OF GEARS ARE INVOLVED.

3 to 1, a 3-step cone, and a 2-speed countershaft, thus giving them only six speeds in all. The presses had originally a back-gear reduction in addition to the fixed-gear reduction, a 4-step cone, and a single-speed countershaft, or eight speeds in all.

Progression—III.

Again, as a compromise between progressions I. and II., and to favor a possible preference for a progression with 10 rather than 2 as a periodically recurring ratio, the following progression may also be looked upon as a candidate:

1, 10 1-12, 10 2-12, 10 3-12, 10 4-12, 10 5-12, 10 6-12, 10 7-12, 10 8-12, 10 9-12, 10 10-12, 10 11-12, 10, 10.10-12, etc., or 1, 1.2115, 1.468, 1.778, 2.154, 2.610, 3.162, 3.831, 4.642, 5.623, 6.813, 8.254, 10, 12.115, etc.

The constant ratio of this progression $\sqrt[12]{10} = 1.2115$ is very close to the geometrical mean of the ratios of progressions I. and II., which is $\sqrt{2\frac{1}{4} . 2\ 1\text{-}3} = 2\ 7\text{-}24 = 1.224$.

Progression—IV. and V.

Finally, a certain interesting simplicity would also be introduced by the adoption of the constant ratio $\sqrt[10]{10} = 1.2589$, thus:

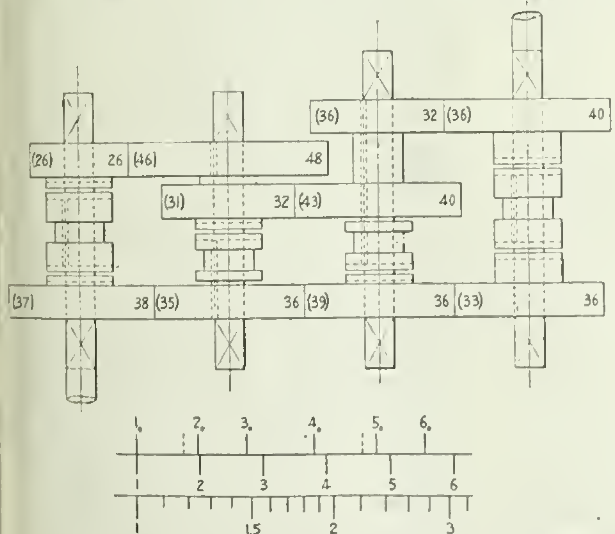

FIG. 9. DIAGRAM OF GEARING OF SPEED VARIATOR OF A WELL-KNOWN MAKE OF PLANER.

Figures in parenthesis show number of teeth in gears as made. Other figures show number of teeth in gears to improve the speed series. Io to 6o logarithmic plot of original relative speeds. 1 to 6, logarithmic plot of improved relative speeds.

1, 10 1-0, 10 2-10, 10 3-10, 10 4-10, 10 5-10, 10 6-10, 10 7-10, 10 8-10, 10 9-10, 10, 10.10 1-16, etc., or 1, 1.2589, 1.5848, 1.9953, 2.5119, 3.1623, 3.981, 5.012, 6.310, 7.943, 10, 12.59, etc.

It will be noticed, however, that there is in reality a theoretical difference only between progression II. and this progression, the tenth number, 7.9431, of this being less than 0.8 of one per cent. smaller than the tenth number, 8, of the former. The best comparison of these four progressions is, however, made by plotting them on a logarithmic scale, as in Fig.

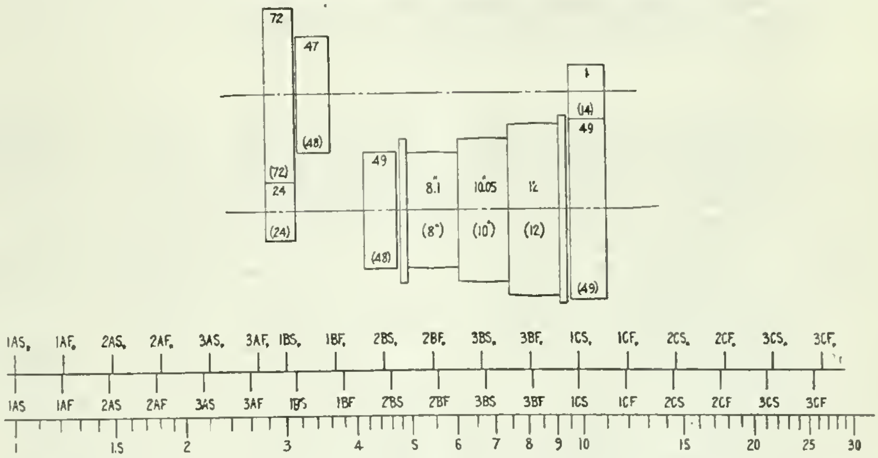

FIG. 10. DIAGRAM OF LIVE HEAD OF A WELL-KNOWN MAKE OF LATHE.

Figures in parentheses show respectively the number of teeth in the gears and the diameters of the cone pulleys as made; the other figures indicate a simple change that would further improved a very good series; IASo to 3CFo, logarithmic plot of original speeds; IAS to 3CF, logarithmic plot of improved series.

2, on which is also plotted the progression that represents the relations between the number of vibrations of the strings of a piano, the constant ratio of which progression is $\sqrt[12]{} = 1.05947$. Having thus indicated that there may be a choice of standards, the writer will further on give some pretty strong reasons for favoring progression I., admitting at the same time that under certain conditions every other term may be omitted, thus leaving the progression:

$1, \sqrt{2}, 2, 2\sqrt{2}, 4, 4\sqrt{2}, 8, 8\sqrt{2}, 16$, etc., or 1, 1.4142, 2, 2.8284, 4, 5.6568, 8, 11.3137, 16, etc.

Standard Feed Series

What has been said above in discussing the adoption of a standard speed series holds equally good for a standard feed series, except for the most up-to-date designs of lathes, in which the feeds for plain turning are obtained as a constant fraction of the screw-cutting feeds. For these latter it is suggested that both the cross-feeds and the longitudinal feeds be made the same fraction of the screw-cutting feeds for all lathes regardless of size. Such an absurdity as a reputable manufacturing concern putting on the market at the same time a 20-in. lathe with this fraction about 0.25, and a 16-in. lathe with this fraction about 0.4, is indeed a severe indictment of the whole lack of system, both of designing and of buying machinery, that still prevails.

Progression—VI.

In paragraph 1134 of Mr. Taylor's "Art of Cutting Metals," the author gives his original classification of hardness of metals in terms of their relative cutting speeds, all other conditions being maintained uniform, thus: If 0 stands for the ideally softest grade of any kind of metal, he made class 1 represent a metal just enough harder to reduce the cutting speed by 1.1; class 2 by 1.1^2; class 3 by 1.1^3, etc., or by factors in the following geometrical progression:

Class 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, etc.; 1, 1.1, 1.21, 1.331, 1.464, 1.6105, 1.776, 1.949, 2.144, 2.358, 2.594.

The writer has since modified this to Class, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, etc.; 1, 2⅛, 2¼, 2⅜, 2½, 2⅝, 2¾, 2⅞, 2, 2.2⅛, 2.2¼, etc., or 1, 1.0905, 1.1892, 1.2968, 1.4142, 1.5422, 1.6818, 1.8340, 2, 2.1810, 2.3784, etc., as being more rational, because then we have the great simplicity that a difference of eight hardness classes corresponds to a difference of exactly 2 to 1 in cutting speeds. It will be seen that this progression is just the same as progression I. with intermediate terms interpolated, hence the simplicity of this for a speed progression in conjunction with VI. for a hardness scale. It would mean that a tool would last just the same length of time on two materials two hardness classes apart, if run on the softer grade with a certain speed and upon the harder grade with the next slower; this is perhaps best brought out by the logarithmic plot in Fig. 3.

Again, in paragraph 732 of "On the Art of Cutting Metals," it is stated that, approximately, the cutting speed varies inversely as the square root of the feed,

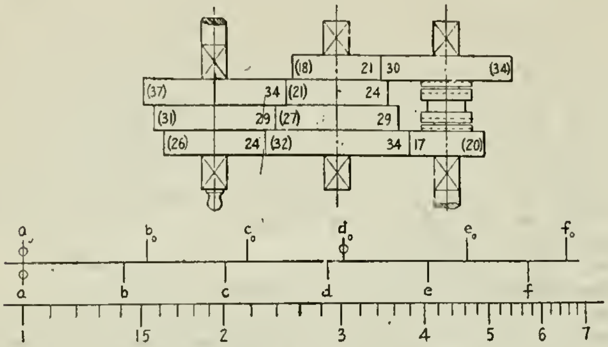

FIG. 11. DIAGRAM OF GEARS IN FEED BOX OF A WELL-KNOWN MAKE OF DRILL PRESS.

Figures in parentheses show number of teeth as made; other figures show improved number of teeth; a° to f° logarithmic plot of original feeds; a to f, logarithmic plot of improved relative feeds; these conform quite closely to progression (V), page 9.

which is a compromise between the special laws for steel and cast iron. Therefore, if in connection with a series of speeds conforming to progression I. we also have a series of feeds in the same progression, the relation of these feeds and speeds to each other will, in order to maintain all other conditions uniform, be as represented by the logarithmic plot in Fig. 4. Thus, for example, if 32 r.p.m. and 0.1 in. feed on a material of a certain hardness grade allow a tool to last a satisfactory length of time, this time would be practically maintained undisturbed if we increased the feed to 0.141 in. and dropped the speed simultaneously to 26.9 r.p.m., the depth of cut remaining the same; or, in general, in dropping or increasing the speed by a step at a time, we would increase or drop the feed by two steps at a time.

By combining the plots in Figs. 3 and 4, as done in the slide rule Fig. 5, we also most readily recognize that a change of one or more numbers in the hardness class of metal cut will have no effect on the cutting speed if we meet this with a change of feed involving a corresponding number of steps, increasing the speed as the hardness goes down, decreasing it as the hardness goes up. Finally, in paragraph 700 of "On the Art of Cutting Metals" is given the relation between cutting speed and the life of a tool in cutting steel, which is, that the speed varies inversely as the eighth root of the time the tool will last, all other conditions remaining uniform. Adding this relation to the slide rule in Fig. 5, we get the rule shown in Fig. 6. Thus, the further simplicity that for every change of one hardness class not accompanied by a change in feed or speed, or for a change

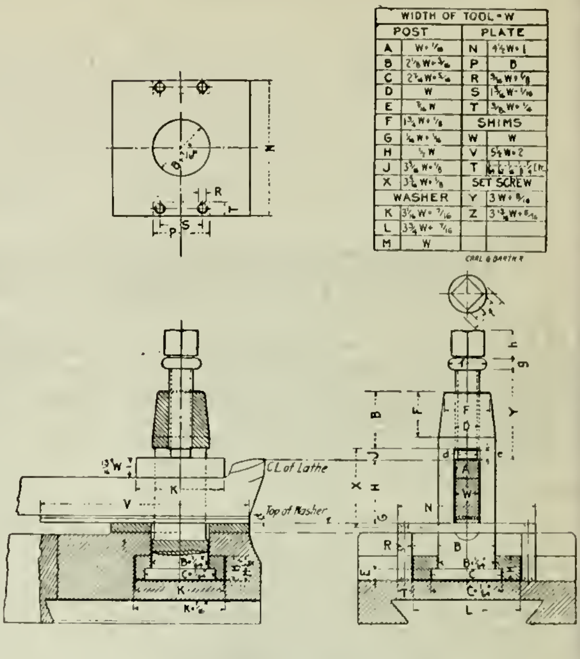

FIG. 13. PROPORTIONS USED BY AUTHOR FOR THE SWIVEL FORM OF TOOL POST FOR MODERATE-SIZED LATHES.

of feel from one step to the next, the life of the tool will be affected 2 to 1, in the one direction or the other, as the case may be.

The writer's preference for progression I. and his hope for its eventual universal adoption will now be fully understood by those who have already given some attention to the scientific control of machine utilization, and also by others who with an unbiased mind have tried to follow the arguments here advanced. A further argument is that this progression represents a fair average of the speed series provided by certain well-known machine-tool builders in some of the machines produced by them in recent years, after they had realized that the time had come for the provision of closer speed regulation, even if this meant a considerable reduction of the ratio of the fastest to the slowest speeds obtainable.

An example of this fact is represented in Fig. 7, which shows the speed ratios of nine 16-in. lathes offered by six different manufacturers in answer to an inquiry in February, 1914. One manufacturer offered three different designs and a second two different designs. It will be noted that the difference between the speed series provided in the different designs of the same maker differ as much among themselves as do the designs of different makers, except in the case of lathe No. 1, which represents the least up-to-date design. To make the diagram clearer, the speed ratios are laid out for a single forward countershaft speed only, thus showing only every other ratio of the full progression intended.

The objection previously considered, that the adoption of standards may to

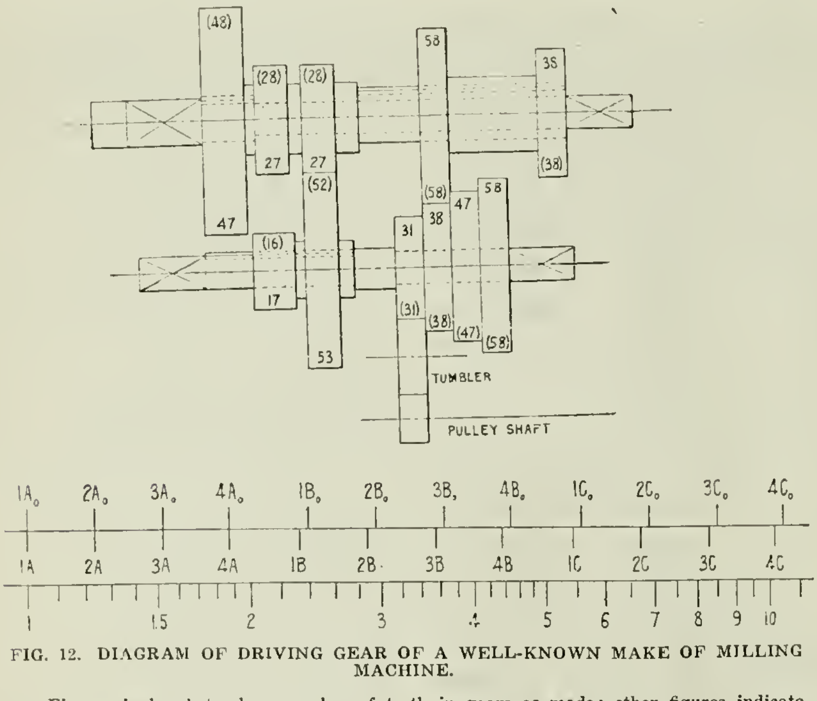

FIG. 12. DIAGRAM OF DRIVING GEAR OF A WELL-KNOWN MAKE OF MILLING MACHINE.

Figures in brackets show number of teeth in gears as made; other figures indicate number of teeth in gears to further improve an already excellent speed series; 1A° to 4C°, logarithmic plot of original speed series; 1A to 4C, logarithmic plot of improved speed series.

some extent block the way for improvements, certainly does not hold good to the same extent, if at all, when it comes to such a purely mathematical matter as a speed series; but it will, on the other hand, relieve designers from wasting time in worrying over what sort of speed series to provide every time the question comes up, which has been the case in the past, and still is now in a very large measure. Even so, numerous designers for the reasons given earlier in this paper, will have difficulties enough in making their inventions conform to any standard speed series, and, in addition thereto, in selecting gears of such numbers of teeth that the closest possible approximation to the various theoretical transmission ratios may be obtained.

Most designers of the present day, whether mathematically inclined or not, are familiar with the use of the simple slide rule in selecting practical numbers of the teeth for a gear and pinion of a single set of gears to give a certain ratio as closely as possible; but a simple logarithmic-scale method for getting the closest possible approximation to a given ratio when two sets of gears are involved, which the writer has used for some years past, is not generally known, if indeed at all known to anybody who has not worked with the writer in connection with these matters. This method will be fully disclosed by a single illustration embodied in the diagram Fig. 8, and we will take for our example the ratio $4\sqrt{2} = 5.6568$, with the restriction that neither pinion is to have less than 14 teeth, and that the sum of the numbers of the teeth in the one set of gears is to be 80, and in the other 60.

By means of a logarithmic scale, which is shown just below the significant part of the diagram, lay off the ratio 5.6568 from a to b. Now place the graduation point for 14 on the logarithmic scale, representing a pinion of 14 teeth, at a, and make a mark at the graduation point representing the gear that would be a mate to this pinion, namely, one having $80 - 14 = 66$ teeth. This operation is indicated by the logarithmic scale above the significant part of the diagram. The distance ac then represents the ratio 66/14. Similarly, 15 is placed at a and a mark made at 65, 16 is placed at a and a mark made at 64, and so on, as far as will eventually appear necessary. Next, below the line place the graduation point 14 at b, and mark off towards a the point for the mate for this pinion in the second set of gears, namely, $60 - 14 = 46$. Repeat for 15 and 45, 16 and 44, etc.

On completion of this repeated operation we at once discover that the closest coincidence between the marks on both sides of the line ab is for the two sets of gears 65/15 and 34/26, whose combined ratio is 5.6667, which is less than 0.2 of one per cent. greater than 5.6568. It will also be seen that the two combinations 59-21×40-20 and 58-22×41-19 come quite close to the required ratio. Of course, special requirements may often complicate a problem of this kind in various ways, but the method described can always be used as a help in its solution. However, no further consideration will be given the matter here.

As an answer to numerous designers who look upon the striving for such close approximations to theoretical ideals as pure nonsense, the writer will say that a little more intelligent persistence in these matters soon educates a man to a point where it takes him no longer to determine close approximations than rough ones, with a genuine additional pleasure added to his work. Among additional helps in arranging speed and feed series as advocated, any otherwise desirable group of gears of the following numbers of teeth will be found to lend themselves admirably for use with a tumbler gear:

88/88	74/88	62/88	52/88	44/88	37/88	31/88	26/88	22/88
88/88	88/74	88/62	88/52	88/44	88/37	88/31	88/26	88/22
1.1	1.1892	1.4194	1.6923	2	2.3784	2.8387	3.3846	4

Comparing these ratios with the writer's ideal progression 1., it will be seen that the deviation is nowhere greater than 0.7 of one per cent. Cone gears made with teeth of any multiple of the following also give ratios differing less than 1.02 per cent. from conformity with the same progression:

8/16	9/15	10/14	11/13	12/12	13/11	14/10	15/9	16/8
2	1.6667	1.4000	1.1819	1	1/1.1819	1/1.4000	1/1.6667	1/2

To further emphasize how even some fair attempts at regular progressions of speeds and feeds have fallen short of what might have been attained, Figs. 9, 10 and 11 are submitted as a few of numerous cases that have been investigated by the writer; but specific cases showing absolute ignorance on the part of designers of these matters will not be referred to at this time. Fig. 12 also shows how even a quite excellent speed series may be further improved.

Power of Machine Tools

While the adoption of a standard speed series for all machine tools would be a wonderful step in the right direction, to get the greatest advantage from this it would have to be accompanied by the adoption of a standardized amount of power for each size machine of a certain type. However, the adoption of the latter without a standard speed series would be of but little, if any, advantage.

Tool Posts for Lathes

In "On the Art of Cutting Metals," which Mr. Taylor wrote under great pressure, and in which accordingly the proper consideration was not given to certain subjects, the mistake was made of advocating cutting tools with moderate clearance angles; without at the same time calling attention to the fact that these can be used only in connection with tool posts in which the body of the tool is raised parallel to itself as the tool is ground down to a smaller height. Several (so far as the writer knows, only unsuccessful) attempts have been made to construct tool posts for elevating a tool parallel to itself without the use of shims. At the present time it seems impossible, therefore, to recommend any but the time-honored forms of tool posts, so arranged that an operator will be unable to modify materially the effectiveness of the cutting angles of a standardized tool by careless insertion and adjustment.

In Fig. 13 are shown proportions for the swivel form of the tool post for moderate-sized lathes which the writer has used as a standard for several years past. The most essential part of this, as regards size, is the width of the slot.

D	A	B	C	E
BOLT DIAM.	1 1/2 D	5/8 D + 7/64	1 3/4 D + 5/32	1/32 D + 1/64
3/8	9/16	11/32	13/16	1/32
7/16	21/32	25/64	59/64	1/32
1/2	3/4	27/64	1 1/32	1/32
5/8	15/16	1/2	1 1/4	1/32
3/4	1 1/8	37/64	1 15/32	1/32

1 1/4	1 7/8	57/64	2 11/32	3/64
1 3/8	2 1/16	31/32	2 9/16	3/64
1 1/2	2 1/4	1 3/64	2 25/32	[illegible]

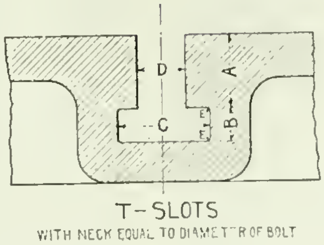

FIG. 14. AUTHOR'S PROPORTIONS FOR T. SLOTS.

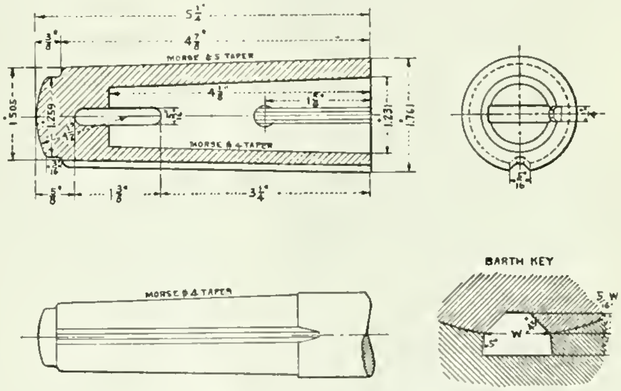

FIG. 15. AUTHOR'S KEY METHOD OF DRIVING DRILL, ARBOR AND BORING BAR SHANKS.

which is for a tool body of approximately 1/30 of the swing of the lathe over the bed, and a distance from the centre of the lathe to the tool-supporting plate that corresponds to the ground height of the roughing tools shown in "On the Art of Cutting Metals." The propriety of these propositions is decidedly open to discussion, however, particularly the latter.

T-Slots

An exceedingly important part of the machine equipment of a shop are the T-slots in various machines, and the writer has also spent a great deal of money in bringing these to a standard, a matter that has at times meant entirely new face plates or tables for some machines. A great many years ago experiments were made by William Sellers & Co. to ascertain the strength of T-slots relatively to a T-headed bolt, and on the strength of these, that company adopted a standardized set of slots, which, as later modified by the writer, have also been used by him for several years past. They are shown in Fig. 14.

Lathe Centres, Drill Press and Milling Machine Sockets

The writer has also had to spend a great deal of money in standardizing lathe centres, and drill press and milling machine sockets, and ventures to suggest that the time has also come for the machine-tool builders to help this matter along. It is well known that the Morse standard sockets are no standards at all, but a perpetuated, laudable, although unsuccessful attempt of years ago to establish standards. However, compelled for the time being to accept them as they are, everybody has now at least two standard tapers for sockets and shanks to contend with, namely, the Morse and the Brown & Sharpe. The best the writer has been able to do, therefore, has been to make all lathe centres conform to a Morse standard, so as to enable drills or drill sockets to be directly inserted in either spindle of certain or all lathes in a shop; and to make all milling machine sockets conform to the Brown & Sharpe standard, with Morse drill sockets having Brown & Sharpe shanks for use with these whenever holes have to be drilled in a milling machine.

The writer unqualifiedly recommends the universal adoption of the Brown & Sharpe standards all around, and the use of Morse sockets with Brown and Sharpe shanks during the change. He also recommends the universal abandonment of the tang as a means of driving. We have for years had the ridiculous inconsistency of drill makers, that they still furnish taper-shank drills with the old-style tang as a means of driving and, along with this, extensively advertise and sell various forms of "use-them-up" sockets for drills with the original tang broken off. It puts me in mind of "Peer Gynt" in Ibsen's drama of the same name, when he manufactured and exported idols to China, and, to ease his conscience, also sent missionaries over there to convert the Chinese to Christianity.

More than twelve years ago the writer adopted a modification of the William Sellers & Co. key method of driving as a substitute for the tang of drills, arbor and boring-bar shanks. This is illustrated in Fig. 15, and differs from the Sellers method in the use of a special form of key that has become somewhat known as the Barth key. The virtue of this as a means of driving consists of its being subjected to crushing pressures only, and that it has no tendency to work out of its seat. For a taper drill socket, it has the additional great advantage over the Sellers straight key that the drill shank can be inserted rapidly without any special care.

SPECIAL ALLOYS AND THEIR COMPOSITION

By L. E.

BY means of the alumino-thermic process, metals are produced from their oxides in a practically pure state, free from carbon. Such metals have proved invaluable for a number of purposes, not the least of which is the making of non-ferrous alloys where iron and other impurities must be excluded, and the manufacture of which would be otherwise impossible. Among the most important of these metals are chromium, 98 to 99 per cent., and manganese, 96 to 97 per cent.; the former being chiefly and very extensively used in the manufacture of special high-grade crucible steels. The latter is mainly employed for making non-ferrous alloys, and one of the special features of this metal is the ease with which it alloys with copper, zinc, tin, aluminum, nickel. etc. Amongst other metals may be mentioned 75 per cent. ferro-chromium and 60 per cent. ferro-chrome-cobalt.

Improves Nickel Alloys

A small addition of manganese to nickel alloys has been found most beneficial, and gives a bright color resembling silver. For nickel castings manganese is used as a deoxidizing agent to produce greater density. In this case about 2 per cent. manganese is added to the molten nickel. In mints, manganese is added to copper-nickel alloys (25 to 7) to the extent of about 2 per cent. Manganese-copper with 30 per cent. Manganese, technically free from iron is now very largely used for a variety of purposes, such as in cupro-nickel, brass, and aluminum alloys, with far better results than an alloy containing iron. In aluminum alloys an addition of about 1 per cent. manganese in the form of 30 per cent. manganese copper is a good substitute for nickel or zinc. Such an addition increases the tensile strength, and gives a casting which can be more easily machined.

Copper and bronze castings lose their brittleness if manganese is added instead of phosphorus. Compared with other deoxidizing agents, such as phosphorus, manganese has the advantage that an excess will tend to improve the quality of the bath. whereas the excess of phosphorus would impair the quality. All castings with manganese alloys should be made under exclusion of air as far as possible. Generally speaking, it is better to add manganese in the form of a high percentage manganese-copper, tin or zinc alloy as the case may be. Alloys of manganese-bronze, manganese-tin, and manganese-titanium, among others, are also made. The latter is said to be probably the best deoxidizing agent for brass and bronze alloys, only about one-third the quantity being necessary, compared with manganese-copper.

Recent Special Alloys

An alloy of ferro-copper 50 per cent. has recently been placed on the market. The alloy is absolutely uniform, in which state it can only be produced by the alumino-thermic process, and is supplied in thin notched plates. For introducing vanadium and chromium into special mixtures, alloys of vanadium-copper 8 to 9 per cent. Va., and chromium-copper 10 per cent Cr. are supplied. A special alloy for brass has also been recently introduced known as "SAB" alloy, which overcomes the difficulty experienced in getting manganese, tin, aluminum, iron, etc., to alloy by themselves with brass. The difficulty is generally got over by means of an intermediate alloy, such as ferro-zinc, for the purpose of introducing iron. These intermediate alloys, however, necessitate heating the brass to a high temperature which, in addition to causing a loss of zinc, has also the disadvantage of the alloy deteriorating in quality by absorbing oxygen in the form of zinc oxide. By means of the special brass addition, various elements in a definite percentage can be introduced into the copper and zinc bath. If 8 per cent. of the alloy is added to the brass containing 60 per cent. copper and 40 per cent. zinc, a brass will be obtained having a tensile strength of 33 tons per in. and elongation of 30 per cent. The product has a golden yellow color, and is distinguished by its resistance to atmospheric influences, to acid and alkaline solutions, as also to sea and mine water. It can be easily worked, forged and pressed. In order to make the special brass an alloy of 60 per cent. copper and 40 per cent. zinc is made from the purest copper and zinc, free from lead, and 16.5 pounds of the special alloy is added to every 204.6 pounds of brass; in doing this, the temperature must be kept so low that the brass bath only smokes.

WHAT is claimed to be the latest development in the uniflow engine consists in arranging the steam admission at the center instead of at the ends of the cylinder. This new design confines the heat to the central valve chest section; the cylinders which are single-acting have each a short. light piston which operates its own exhaust port.

AN interesting performance with oxy-acetylene apparatus recently consisted in cutting a steel disc die-block 14x18x36 in. into two pieces 14x16x18 in. The block weighed 2,382 lbs. and was cut with a Davis-Bournonville torch, style 3000, with a No. 5-8 tip. The cut was made in 9½ minutes, and the gas consumption was 325 cu. ft. of oxygen at 130 lbs. per sq. in. and 12 cu. ft. of acetylene.

FOUNDRYMEN AND PRICE CUTTING

By "Cupola."

IF there is one question more vital to the foundryman than another it is the question of price-cutting. Other trades are beginning to see that the evil of price-cutting is ruinous to the foundryman. No less than any other line, and particularly to the jobbing foundryman. The manager of a large foundry, in speaking upon this subject, stated: "It just amounted to this. We had to buy over several specialties and acquire the sole manufacture of them, or close down. This expenditure meant thousands of dollars of new capital, scrapping a whole lot of accumulated equipment, of which there is no end in a jobbing shop."

There's no reason in the world why a jobbing foundry should not be a paying venture, and it is only a matter of time when such will be the case. All over the country foundries are doing as this manager stated, and if the jobbing foundryman will take advantage of the situation and demand a living price this evil of price-cutting will soon be a thing of the past.

Effect on the Moulder.

The evil of price-cutting has an effect upon the moulder which is detrimental. He hears that the boss took such a job at so much per lb. He figures it out in his own crude way something like this: "'Well, wouldn't that skin yer! The boss has taken this job at so much per lb. Iron costs so much. It takes ten of us two hours to take off a cast. It takes Jimmy six hours a day to get the cupola and ladles ready, then he has coke, cores and losses. The castings have got to be rumbled, bagged and shipped. It will take us fellows all our time to put up so many boxes a day, because the castings only weigh so much a piece. That don't allow a cent for profit. I'll be darn'd if I know what he's thinking about. I'm not going to work like Sam Hill to make him money at that price."

The boss says: "But look here, chaps. I simply had to take the job to keep you fellows going. So & So offered to take it at ¼ of a cent less, but Brown's a friend of mine and I got the ¼ of a cent more."

The writer has been up against this "Friend of Mine," and is very pleased to say, has lost a lot of friends. Job said, "Lord preserve me from my friends." The moulder who knows that the boss is price-cutting is like the sailor who finds the captain boring a hole in the bottom of the ship to let the water out, and beginning to see that all the pumping in the world won't save the ship, he refuses to pump any faster.

Back-Bone Wanted.

What is needed is better business methods, more back-bone ,"less friends," less of the "well if Smith can let you have them at 3 cents I can" kind of methods. There's not a foundryman on this earth that can give a price on a line of castings unless he has moulded the job before. Every casting has some peculiarity of its own. It depends upon how they're gated, or whether the castings have to be machined or not, and a thousand and one little things to be considered.

Before a price is given there should be a test made if there is any quantity; for a few tons, however, there should be no juggling of prices, but a straight time and material invoice rendered. There are buyers of castings to-day that do nothing but peddle their castings all over the country and pose as "friends of mine" to the limit, simply because they know that on an average the jobbing foundryman is a poor business man.

In this way foundrymen who, in actual fact, are the beginning of the mechanical world, are the poorest financially, of any of the allied craftsmen.

Can Buy Castings Cheaper.

It's a very common thing to hear the head of a large machinery company, when asked why they buy their castings instead of running a foundry to reply, "Run a foundry? Not on your life. We can buy castings cheaper than mould them and have no worry. If we get bad castings it's not our loss; it's the other fellow's."

There are various reasons for this state of affairs. For instance, a contract has been taken to turn out castings at a certain price, and there is scarcely enough weight in a day's moulding to to take off a melt. The foundryman thinks, "Now, if I could only get another job with a bit more weight in it, I could make good on this job." So out he goes looking for a bit more weight, and he's so anxious to get weight that price is a secondary consideration; thus possibly spoiling a customer and lowering a fair price, with the result that some day he'll be handicapped with "more weight" than price. Buyers of castings begin to play upon the foundryman in more ways than one.

What Is Wanted.

Now, what is wanted is this. The foundryman should find out what it costs him to do business. He should say to himself, "Well, if I was working for So & So, he'd give me $150 a month," and begin like this:

Overhead Expenses For One Year.

Own salary, $150 a month	$1,800.00
Rent of foundry, $25 a month	300.00
Telephone	45.00
Stationery and postage	25.00
Bookkeeper	600.00
Fire insurance	50.00
Laborer at $2.50 a day, 300 days	750.00
Cupola man, $3 a day	900.00
	$4,470.00

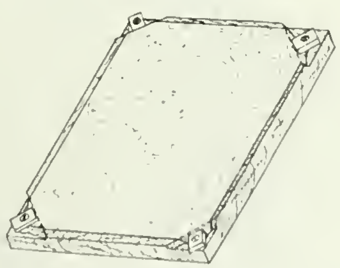
An average of $14.90 per day for 300 working days. And there are other little incidentals which creep in.

It may be stated that a laborer and cupola man need not be classed as an overhead expense, but both these men are just as indispensable as the boss. The writer was in a foundry not long ago and asked for the manager. He was told to go into the foundry. And there was the boss with his sleeves rolled up, working at a job which the laborer should have been doing. That was all that boss was worth, but he may have been drawing a couple of thousand dollars a year. This particular foundry was employing, on an average, 25 men all the year round, and not paying a dividend, just holding its own, and lucky at that.

SERVICEABLE EMERY CLOTH BOARD

By D. A. Hampson.

WHERE emery cloth is used to polish and burr off small parts, the sheets are generally tacked on a board or on the bench, or the corners weighted down. These are unsatisfactory ways at best, consuming much time in changing sheets and not presenting a solid, flat face. Then, too, the edges and corners are more or less blocked off and the sheet of cloth is worn in the centre, over little more than half its area. Such waste of cloth and time, spent on poorly done work, represents a decided loss.



SERVICEABLE EMERY CLOTH BOARD.

A better way is to make up a set of emery "boards" either like the one illustrated, of wood or of cast iron. If of the latter, a section ¼ in. thick, ribbed all around with two centre cross ribs, makes a board light enough to carry around easily, and heavy enough to stay in place on a bench. The face should be planed.

If made of wood, well selected and thoroughly dried, the board will be accurate and lasting. It is better to make the board of two thicknesses, with the grain crossed, as shown, nailed or screwed together, in preference to glue. The outstanding feature of the board, however, is its economy—the emery cloth being quickly changed and always drawn taut and nearly all of its surface available for unobstructed working. At the corners are metal clips which clamp the sheet and, by drawing against the bevel face of the cut-out corner, pull it flat without wrinkling it. The screws thread into nuts set in the under side of the board.

Unless carefully watched, workmen are prone to be wasteful of emery cloth, throwing away sheets which are but half used up, dirty, or useful for other purposes. Emery cloth can now be obtained in narrow rolls, which are more economical than the practice of tearing up strips. Emery cloth which is dirty can be brushed out with a stiff brush (even a file card will do) and its surface thereby renewed. When the work is oily or greasy, the cloth gets filled up and smooth very soon after put in service, but it is easily cleaned with kerosene and a soft bristle brush. For many purposes used emery cloth is better than new—the "scratch" is off—and sheets that are ordinarily thrown away, can be saved and used again. If dry and not torn, a used sheet of one grade is as good for service as a sheet of one or two grades finer.

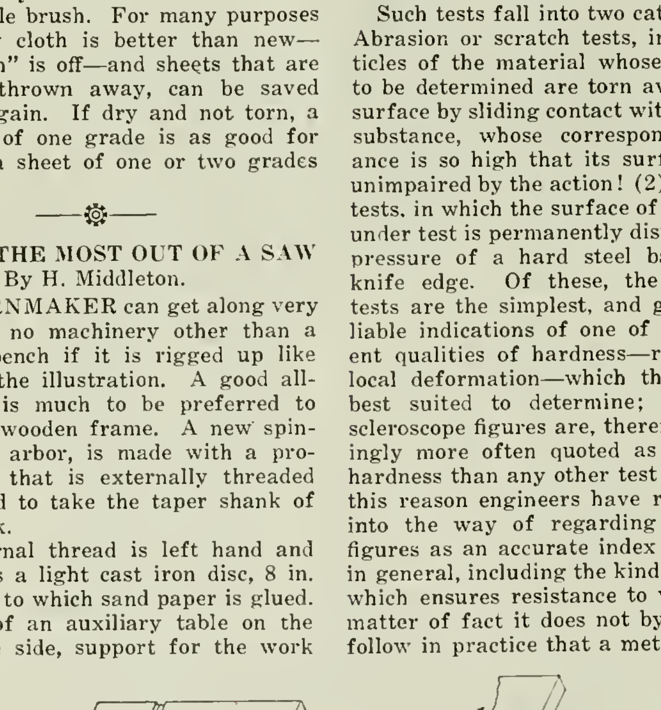
GETTING THE MOST OUT OF A SAW

By H. Middleton.

A PATTERNMAKER can get along very nicely with no machinery other than a good saw bench if it is rigged up like the one in the illustration. A good all-metal saw is much to be preferred to one with a wooden frame. A new spindle, or saw arbor, is made with a projecting end that is externally threaded and is bored to take the taper shank of a drill chuck.

The external thread is left hand and on it screws a light cast iron disc, 8 in. in diameter, to which sand paper is glued. By means of an auxiliary table on the shelf at the side, support for the work is provided across the centre of the wheel. Having no nut at the centre, the entire face is available for sanding patterns, rounding corners, putting on "draft," etc. The uses of a sand wheel are legion and new ones are constantly presenting themselves.

When it is desired to drill holes, the disc is taken off and the drill chuck put in the spindle. Various face plates, side and angle gauges for odd drilling, are made of wood. This makes a low-priced, good, all-round outfit for a patternmaker. Complete with ¾ horse-power motor it should cost less than $200, and is all any man with a small business needs.



GETTING THE MOST OUT OF A SAW.

WHAT IS "HARDNESS"?

By L. Street.

THE word "hardness," as loosely used in everyday engineering talks, has no precise meaning. It calls up in the mind a complex image of a substance which is not easily scatched or dented, is liable to snap rather than bend, and will be likely to give trouble in machining and resist wear. "Hardness" is a utility word that carries all these associations. One can, however, use the word in a more definite sense, and speak of the hardness of a substance as determined by one or other of the hardness tests.

Such tests fall into two categories: (1) Abrasion or scratch tests, in which particles of the material whose hardness is to be determined are torn away from its surface by sliding contact with some other substance, whose corresponding resistance is so high that its surface remains unimpaired by the action! (2) indentation tests, in which the surface of the material under test is permanently distorted by the pressure of a hard steel ball, cone, or knife edge. Of these, the indentation tests are the simplest, and give very reliable indications of one of the component qualities of hardness—resistance by local deformation—which the method is best suited to determine; Brinell and scleroscope figures are, therefore, accordingly more often quoted as measure of hardness than any other test result. For this reason engineers have rather fallen into the way of regarding indentation figures as an accurate index of hardness in general, including the kind of hardness which ensures resistance to wear. As a matter of fact it does not by any means follow in practice that a metal which resists indentation will in the same measure resist abrasion.

A Complex Characteristic

Hardness is not a specific property, like elasticity or tensile strength, but a complex of many characteristics which, so far as present knowledge goes, cannot be determined by any single test. The indentation test informs us of resistance to deformation; any one of the many possible abrasion tests will indicate resistance to wear under conditions similar to those obtaining at the test; but it is not possible to argue from one kind of the test what the qualities of the material will be under any other.

The Committee appointed by the Institutional Engineers in 1914 "to report on a hardness test for hardened journals and pins," describes in its report an ingeniously contrived series of tests to determine resistance to rolling abrasion with a view of comparing the results of such tests with the Brineli and scleroscope hardness numbers. The conclusions reached, while distinctly informative in many ways, make it clear that the Brinell hardness numbers of a miscellaneous selection of steel are not a safe guide in predicting their relative resistance to wear.

Results Not Interchangeable

As an example of the difficulties that surround the task of finding a law whereby the results of hardness tests of various kinds might be interchangeable, the process of skin-hardening which goes on under wear with some grades of steel, more particularly manganese steel, is especially noteworthy. Manganese steel, though it cannot be tooled, is really quite "soft" material. Its prime quality is toughness; its hardness is only about 200 Brinell. As soon, however, as it is subjected to a crushing or rolling action, producing deformation, the skin of the surface takes on quite another structure, passing from 200 Brinell hardness to 300, or even 500. This is a peculiar property, and explains why it is so difficult to tool a steel of such comparative softness, the reason being that the material hardens to the pressure of the tool. For this reason alone hardness cannot be expressed in terms of single value. It can only be expressed, by a complete stress strain curve.

MECHANICS TRAINING COLLEGE

AN arrangement has been come to between the Amalgamated Society of Engineers and the local employers in the district of Dudley, England, which will greatly facilitate the founding and work of a training college for engineering mechanics. The principal object of the scheme is to enable boys engaged in workshops to improve not only their ordinary education, but acquire a proper grounding in mechanics, geometry, and mechanical drawing. The question of remuneration seemed to offer possible grounds of disagreement, but with the amicable settlement of this point the scheme is being proceeded with.

The college training begins at the age of 16, and on attaining the age of 18 the employee-student will continue his studies outside of working hours. It is also stipulated that class attendance will not affect the earnings of the pupil so far as factory conditions are concerned. The scale of payment is fixed till the student is 21 years of age.

Uniform System of Foundry Cost Accounting

To promote the adoption of a uniform system of foundry cost accounting among its members, the American Foundrymen's Association has outlined a plan of procedure which represents the most comprehensive effort in this line of endeavor that has ever been undertaken.

FOR some years the American Foundrymen's Association has had had cost committees at work which have presented valuable reports at the annual meetings of this society, but unfortunately a large part of this work has been without practical results owing to the fact that the members, in only a few instances, have followed the recommendations made.

To make this work more practical and to facilitate the installation of uniform cost-keeping methods in the plants of the members of this association, it has been decided to provide them with the personal service of a cost expert whose duty it will be to make the existing cost systems conform to the one that is to be adopted. Without the services of a cost accountant to introduce the system, no headway can be made toward uniformity of practice, which is the underlying basis for intelligent estimating among competitors.

Since the American Foundrymen's Association, due to its low cost of membership, is without means to carry on this special work, it was decided to raise a fund by subscription among those who desire to participate in the benefits to be derived from this undertaking. The plan will enable foundrymen to obtain a cost accounting system at a nominal cost, which will be representative of the latest and best practice in cost-keeping methods.

Productive labor is a good measure of the value of the business transacted by a foundry and, therefore, the expense of this undertaking will be prorated on the basis of the number of molders and coremakers employed. The schedule of charges that will apply, follow: Foundries employing up to 40 molders and coremakers, $50; from 40 to 200 molders and coremakers, $1.25 for each molder and coremaker employed; for plants employing more than 200 molders and coremakers a flat charge of $250 will be made. Since additional traveling expenses will be involved in the installation of the system outside of the industrial centers of the United States and Canada, an extra charge will be made for this service west of the Mississippi river, south of the Ohio river, and outside of the Province of Ontario, in Canada.

Payments are to be made on the following basis: Twenty-five per cent. when subscribing to this special fund; 25 per cent. upon the receipt of the book containing the uniform cost system; 25 per cent. after the system has been installed by the cost expert and the remaining 25 per cent. after the subscriber has received from the cost accountant a written report covering the system in use with suggestions to make it conform to the uniform method to be adopted.

To carry on this work, the Cost Committee of the American Foundrymen's Association has engaged the services of C. E. Knoeppel & Co., New York, industrial engineers and cost accountants. Data are now being gathered preparatory to the compilation of a uniform system of cost-keeping for foundries, which can be adopted to shops specializing in the manufacture of gray or malleable iron, or steel castings. The problems of the foundry which is a department of a manufacturing plant and produces no castings for the trade will be considered and provision also will be made for specialty, light and heavy work shops.

When the uniform system has been ratified by the Cost Committee, it will be printed in pamphlet form and will be distributed among all of the subscribers. As soon as possible thereafter, cost experts in the employ of C. E. Knoeppel & Co., will visit each one of the plants of the subscribers and will point out the features of the cost system and will aid in its installation. This personal visit will be followed by a written report by the cost expert who will detail every step to be followed in the introduction and use of this system. For a reasonable time thereafter, the advice of C. E. Knoeppel & Co., can be had by correspondence without additional cost to the subscriber.

Subscribers to this fund are limited to the membership of the American Foundrymen's Association, but foundries not so enrolled can derive the benefit of this great work by becoming members of this organization.

Furthermore, only subscribers to this special fund will receive a copy of the uniform cost system and the services of C. E. Knoeppel & Co., membership in the American Foundrymen's Association alone not entitling those so enrolled to participate.

Favorable replies already have been received from 217 members of this organization in the United States and Canada, and 51 have forwarded their subscriptions. This is sufficient assurance that the plan can be carried to a successful conclusion, and it marks the beginning of the greatest uniform cost campaign ever undertaken in a single industry.

The members of the Cost Committee, who conceived this undertaking, follows: B. D. Fuller, chairman, Westinghouse Electric Mfg. Co., Cleveland; H. J. Koch, Fort Pitt Steel Casting Co., McKeesport, Pa.; J. Roy Tanner, Pittsburgh Valve Foundry & Construction Co., Pittsburg; C. R. Messinger, Sivyer Steel Coating Co., Milwaukee, and A. O. Backert, secretary Twelfth and Chestnut Streets Cleveland.

difficulties confronting the Western pub-

POWER FOR STEEL MILLS

FROM a report of the central station power committee of the Association of Iron and Steel Electrical Engineers, submitted at the recent meeting in Chicago, the following has been taken, and for which we are indebted to the *Iron Age*.

The rate schedule of 20 power companies furnishing power to steel mills has been obtained. To permit comparisons the net resultant rates for 1000-kw. and 5000-kw. loads at 50 per cent. load factor were calculated, which calculations gave the following results:

NET RATES PER KW.-HR., 50 PER CENT. LOAD FACTOR.

	Maximum	Minimum	Average
1000-kw. demand	1.246c	0.700c	0.9417c
5000-kw. demand	1.060c	0.667c	0.8464c

The demand, including the effect of power factor upon it, is just as important a part of a proper rate schedule as is the energy charge. A mill with a load factor of 70 per cent. and a power factor of 80 per cent. or better can be served at much less cost than a mill having a load factor of 35 per cent. and a power factor of 50 to 70 per cent.

Rate Schedule

Rate schedules should be as simple as possible and avoid complicated systems of rates and discounts for varied load factors and consumptions. Where the mill can so adjust its operations as to permit keeping off the central station peak there should be a lower rate than for peak service. Some of the power companies reporting charge only 50 per cent. of the peak demand rates for off-peak service only.

We recommend that in negotiations for central station power service, and in order to obtain most favorable rates to the purchaser, it be insisted that the rate schedule be divided into demand charges and energy charges; that the demand be the average or integrated peak of 15 to 30 min. duration; that the power factor be 80 per cent., with decrease or increase in the demand to be charged for accordingly as the power factor is above or below 80 per cent.; that the demand charges per kilowatt be in two or more steps; that the energy charges per kilowatt-hour be in two or more steps; that any excess demand occurring at other than the peak period of the power company's plant be charged at only one-half the demand charge normally applying for such excess if occurring on the power company's peak period. With rate schedules on the basis recommended, the mill engineer will obtain the benefits due to good operating conditions and not be obliged to pay for the poor conditions of another consumer's load.

The user of electric power is enabled to collect engineering data, such as capacity of machines, load curves, power requirements, maximum demands and power consumption, and, in addition, to provide a means of analyzing the cycles of operation throughout the plant. With such records, the central station can accurately determine the requirements of steel mills and negotiations for the sale of power are greatly facilitated.

The power requirements in steel mills range from 1000 to 10,000 kw. or more. A fair average is about 4000 kw. The load is characterized by large peaks. Where alternating-current service is used the power factor will vary from approximately 65 to 80 per cent. Large generating capacity is required to provide service of the proper regulation.

Application of Central-Station Power

In all large modern central stations, the power is generated and transmitted as alternating current at a voltage considerably higher than is permissible for use around a plant. At the receiving end of the transmission line this power must be retransformed to at least two and generally three lower alternating-current voltages, namely; 6600 or 2200, 440 or 220, and 110; and, where direct-current power is used, further transformation is required from alternating current to direct current.

The 6600-volt or 2200-volt current is used for driving the synchronous motor of motor-generator sets, the large motors driving the mills and some of the larger auxiliaries, say from 100 hp. up for the 6600-volt and 50 hp. up for the 2200-volt for driving pumps, fans, blowers, etc., in those locations where these voltages can be used without endangering life and property.

For the remaining auxiliaries the alternating-current voltage is further reduced to 440 or 220 volts. Motors wound for these voltages have a wide range of application, covering almost all classes of service in the mill, especially where constant-speed characteristics are required.

For lighting 110-volt is generally used and transformed from either of the above voltages. In all of the above transformations a certain percentage of the initial purchased power is lost, the magnitude of the losses being in the order of the motor-generator sets first, the rotary converter second, and transformers third and least.

In some contracts for central-station power the power paid for is that which is delivered to the high-tension side of the transformers connected to the transmission lines, the power being measured on the low side of the transformers, the wattmeter readings on the low side being multiplied by a constant or multiplier which takes into account the transformer losses. In contracts of this class the purchaser pays for transformation losses. In other contracts the power paid for is that which is delivered on the low side of the stepdown transformers, the power company paying the losses of the first transformation, the purchaser paying for all others.

A study of percentage losses incurred in distributing central station power from receiving station to plant feeder station busbars would indicate that in deciding on the other equipment that that equipment should be selected which would entail the least losses to the power delivered to the motors. If this was followed out without regard to other conditions we would select 6600 or 2200 volt apparatus; but physical and safety considerations limit the use of those voltages, and consequently only a relatively small number of the total motor equipment can use them.

Our next choice, so far as efficiency goes, would be for the 440 or 220 volt alternating-current auxiliaries. These can be used in almost all applications where direct-current power is used, the exceptions being where variable speed and dynamic braking are required. The direct-current motors are so much better adapted for this class of service that the disadvantage of greater conversion loss is more than compensated for by their flexibility and adaptability.

The ratio of alternating current to direct current used will vary greatly in different plants, depending on so many factors that no standard can be set. In general, in those plants where power is purchased and where there are many cranes and variable speed drives direct current will probably predominate for auxiliaries about in the ratio of 60 per cent. direct current to 40 per cent. alternating current for voltages of 440 alternating current or less and 250 direct current.

The alternating current is suitable for driving fans, pumps, hot saws, cold saws, conveyors, straightners, drill presses and possibly some mill tables. Alternating-current motors are not favored for table drives, for the majority of them require a wound rotor type of motor, which, as a rule, is more difficult to repair than a direct-current armature, and the direct current is better adapted to heavy table work. Direct current will be used for cranes, tables, charging storage batteries, electrolytic work and variable speed motors, especially those used for driving machine tools. The type of winding to use will depend on the nature of the load and the results sought.

In general, the use of alternating-current motors is recommended where constant-speed, non-reversing conditions obtain, and the direct current where large starting torque, quick-reversing and acceleration, variable speed or dynamic braking are required.

TURBINE GEAR LUBRICATION

By O. C.

WITH the increased use of geared drives there is an increased necessity for minimizing friction, thus reducing the wear and noise and increasing efficiency. The best results so far have been obtained with helical gearing, and the use of this has proved extremely advantageous in the case of turbine drives for marine purposes and for direct current generators. The latest types of double helical gears are, however, those which secure the best results, great accuracy being combined with high efficiency and silent operations. The mounting of all gearing should have extra careful attention, especially as to the support of the pinion in high speed and high power work.

The lubrication of turbine gears is effected by means of special sprays arranged to deliver the oil direct on to the teeth, as to allow such gears to run partially submerged in an oil bath would absorb an appreciable amount of power. The pinions of turbine gears are usually of nickel steel, and the large wheels of cast iron with steel rims. To obtain quiet running, straight-cut rawhide, cambric and paper pinionss are sometimes used; ordinary hydro-carbon oil, however, is most destructive to rawhide pinions, and the fact that rawhide pinions have gained a bad name is entirely due to the use of this lubricant. One of the best compounds for rawhide pinions is as follows:—

Plumbago	15%
Resin oil	55%
Resin	30%

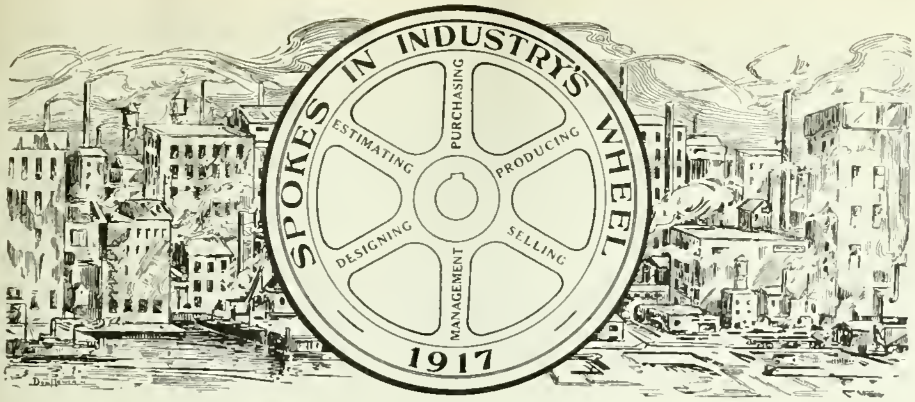
Cloth and paper pinions can be lubricated without injury with ordinary oil.

UTILIZATION OF PEAT AS FUEL

By T. J.

UNTIL recently there has been no system in existence for the utilization of peat on a commercial basis; but a new invention, which recently reached the commercial stage, offers a means of supplementing the existing coal supply and in the meantime providing an ideal charcoal for the trenches. The whole trouble with regard to the utilization of peat has arisen from the difficulty of completely separating the moisture from the solids. It was this difficulty that all inventors had failed to overcome. The process here referred to, known as wet carbonizing, solves the problem. It is simple and works almost automatically. The peat is pumped from a bog into a reservoir, then fed into tubes, which are steam-jacketed and heated to such a high temperature that a complete chemical decomposition takes place in the peat, and the tiny cells are completely disintegrated; in other words, the water and peat become two distinct elements. The remaining process consists in pressing the water out and drying the peat powder before making it into briquettes. The briquettes contain a fair percentage of nitrogen, and are of a high calorific value.

INVESTIGATION shows, according to J. W. Powell, president of the Fore River Shipbuilding Corporation, that the average wages in shipbuilding in Great Britain are 50 per cent. less, and the net output per worker 14 per cent. higher than in American yards. In spite of the vast capital expenditure devoted to the improvements of the American shipbuilding plants during the past three years, which is believed to have placed them in the front rank from the view of equipment, the opinion is put forward that no superiority of design or methods of building can overcome the basic disadvantages of the American industry.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

JOHN WILKIE TAYLOR

THE increasing importance of the shipping industry, which is now being brought before the general public by events not of the pleasantest, is of more than passing interest to our readers, not only on account of the manufacturing activity which is expected to result from present developments, but also because of the more intimate knowledge ensuing with regard to ships' equipment and personnel. The part played by the machine shop in the annual round of marine life in this country is too important to be overlooked. Not only so, but the influence of early experience during the formative period of an engineer's life has more than a little to do with the ultimate niche which he may occupy in industry's gallery.

As chief engineer of the Western Canada Flour Mills Co., Goderich, Ont., John Wilkie Taylor occupies a post of considerable importance not only from a technical viewpoint, but also, at the present moment, from a standpoint of international exigency; a daily capacity of 10,000 barrels of flour by the various plants will perhaps facilitate perception of the reference. Despite the fact that he has a "shore job," Mr. Taylor's success has been largely influenced by a happy combination of constructive and operative experience. Born of Scottish parents at Nottawa, Ont., 1868, Mr. Taylor is Canadian to the core, his life activities having afforded opportunity for becoming intimately acquainted with many widely separated parts of his native land.

His early education was obtained in the public schools of Nottawasaga Township, passing the entrance examinations at 13 years of age. In May, 1880, an apprenticeship was commenced in the establishment of Nathan Veitch, ironfounder and machinist, at Nottawa, and although, as our "Spoke" remarks, the plant was somewhat primitive, the proprietor, by reason of his personal interest in the youthful employee, more than made up for the shortcomings of his equipment. Mr. Veitch was a real "old guard" of the trade, having come from the Howden shops in Glasgow, Scotland, and the thorough manner in which he grounded our friend in the rudiments of the foundry and mechanical trades has been the cause of life-long gratitude on the part of Mr. Taylor.

On the conclusion of his apprenticeship Mr. Taylor spent a year at Collingwood as assistant engineer in a large saw mill owned by the A. M. Dodge Co., of New York. His contact with shipping at this port created a desire for marine experience, and during the three seasons ending 1890 he was in charge of small craft plying from that port. A position as staff engineer with the Great Northern Transit Co. of Collingwood was followed in 1894 by appointment to the post of chief engineer in charge of the fleet of the Dominion Fish Co., Georgian Bay. This position he relinquished for a year to join the Holland and Emery Lumber Co., at Byng Inlet, returning to the former company and superintending the overhauling of their fleet while wintering at Goderich. The year 1900 was rendered memorable in our "Spoke's" life by the burning of the passenger steamer Persia, of which he was chief engineer. The event was not without its recompense, as he had full charge of the rebuilding of the engines, boilers and mechanical equipment, a task which was of considerable value in view of the experience obtained, as was evidenced by the performance of similar work for the Dominion Fish Co., in connection with their passenger steamer Manitou.

JOHN WILKIE TAYLOR.

Recent events have acted as a forcible reminder of the three years from 1904 to 1907, which were spent as chief engineer on the steel freighter Algonquin, this craft having recently fallen a victim to the torpedo of a Hun submarine off the coast of England. Mr. Taylor at this time was a strong advocate for the adoption of quadruple expansion engines, and while a bulk lake freighter of 10,000 tons was so fitted at that time and demonstrated the efficiency of the type of engine, further adoption was negatived by the extra amount of space required. His admiration for this highly developed type of engine was given full scope, when after four years with the Montreal Transportation Co., he became chief engineer of the turret steamer Scottish Hero, of the Canadian Lake & Ocean Navigation Co. This vessel had quadruple expansion engines and had been refitted with Scotch boilers for 215 lbs. pressure, the two years' operation of which provided additional experience of a valuable nature, calculated to render our friend particularly fitted for the control and direction of the extensive equipment for which he is now responsible, and to which he was appointed in 1913, resigning from an important appointment with the Merchants' Mutual Line to accept the position.

The practical experience outlined has been combined with frequent opportunities to study power plant conditions in the States as well as Canada, and Mr. Taylor speaks highly of the degree to which Western Canada industrial equipment has been developed. A feature of Mr. Taylor's success has been the extent to which he relied on self-tuition for acquiring his theoretical knowledge. During early days in lake service, the winter months were spent in machine shops, and evenings devoted to study, the benefits being evidenced by the steady progress in his profession. His advice, therefore, to the young mechanical engineer has the feature of personal success behind it. "I most strongly advise serving an apprenticeship in some good engineering shop along with a technical school training, and throughout life a diligent study of trade and engineering journals.

As is frequently the case with men much occupied in industrial pursuits, Mr. Taylor has not spent much of his time in political matters, being strictly independent in his views. He has, however, been a life-long member of several fraternal socities and a number of Masonic orders, and when he retired from lake engineering was made an honorary member of Midland Council, National Association Marine Engineers.

Mr. Taylor's private life is now spent at Goderich, where he resides with his wife and family on Lighthouse Street, his ability having descended to one son, who is serving in an engineering capacity with the Standard Oil Co. at Taft, California.

TORONTO BRANCH C.M.A. ANNUAL MEETING

EIGHT hundred firms and corporations are now enrolled in the Toronto branch membership of the Canadian Manufacturers' Association, according to the report of the Secretary, H. Macdonald, at the seventeenth annual meeting, held a few days ago. The figures show an increase of eighty-seven on the year. The meeting was held at the Central Technical School and prominent among the matters getting the association support were technical education and the imperative need for its extension.

A wide range was covered by the address of the Chairman, Thomas Roden. Major L. L. Anthes was, by acclamation, elected chairman for 1917-18, and J. Western vice-chairman. Outside of association business, there were brief addresses by Dr. A. C. MacKay, Principal of the Technical School, and Miles Vokes, Chairman of the Board of Education. Several speakers touched on the criticism which had been directed against the Central Technical School by Mayor Church. Resolutions were passed in appreciation of technical instruction; approving the establishing of Government Bureau for industrial research, and for further housing methods on modern lines in Toronto. Nearly all aspects of civic, industrial and public policies were included in the scope of the lengthy reports.

Anticipating the Future

In the Chairman's remarks it was stated that "with Canada approaching one of the most critical periods in her existence, caused by the necessity of readjusting her production from a war to a peace basis, it is imperative upon us as business men to bring our united counsels to bear in an effort to anticipate the problems. The sphere of influence and activities of the association have become so extensive, embracing such great diversifications of interest, yet providing a common ground upon which divergent views may be harmonized, that its deliverances must necessarily take upon themselves as atmosphere of broad and comprehensive statemanship. This same general view has actuated strongly the deliberations of the committee of Toronto branch, and during the year I have had abundant evidence of the respect and esteem in which our association is held."

Trade of Canada

The last fiscal year showed the trade of Canada to have been nearly twice that of 1914-15. The ordinary revenus of the Dominion amounted to about $230,000,000, or $100,000,000 more than that of 1914-15. The revenue of the past year—the largest in our history—will be sufficient to meet all the ordinary and capital expenditures of the country, and in addition pay fifty or sixty million dollars of the expenditures for war purposes. The total trade of the Dominion will be found to have reached about two billion dollars or a billion dollars more than that of the fiscal year in which the war began. Mr. Roden then touched on the duty of manufacturers to co-operate with the Government to meet after-war conditions.

Tariffs

"At an Allies Conference in Paris," he went on, "certain resolutions were adopted looking to the formation after the war of a species of commercial union of the anti-German powers. It is, of course, too soon to presage the nature of the effect, but it is not too soon for all who are engaged in commercial and industrial pursuits to become continuously watchful observers. More care should be exercised in the selection of people before appeals for immigration are made for the sake of labor and good citizenship, and the granting of the franchise should be more carefully considered. Owing to the ignorance of our language on the part of many of our immigrants and the lack of knowledge of our traditions and ideals, many abuses are likely to develop unless restrictive measures are imposed."

Industrial Research Needed

"If there is one thing that is particularly lacking in Canada, it is industrial research. Sir George Foster's appointment of the Advisory Board, of which Professor Macallum is the head, cannot be too highly appreciated. This terrible war with our loss of man-power and increase of taxes necessitates the most careful conservation and utilization of both our natural and industrial resources. To do this, as manufacturers we must be keenly alive to the crisis we shall pass through after the war and lose no time in making definite plans to co-operate in every way to utilize to the fullest the facilities which may be afforded by the Advisory Board."

In the Secretary's report it was stated that by a vigorous campaign to secure a series of scholarships to be awarded by the manufacturers in connection with the day courses at the Central Technical School for the past session, thirty-one scholarships of $25 each were secured. Five more were given at the meeting.

The Executive pledged the support of the Branch in any feasible plan for securing suitable employment of returned soldiers. The number of men who have found employment to date is 3,240. So far as the Commission know there is no discharged soldier able and willing to work who is at the present time out of employment in the Province. The prospects for employment of discharged soldiers in the future seem very bright.

Discrimination Against Home Capacity

The Executive reported having given serious consideration to the subject of the growing and persistent discrimination by Government departments against the employment of Canadian architects, engineers, contractors and manufacturers, in the construction of public works. The policy complained of is viewed as inconsistent with the efforts which are being made through our universities and other educational institutions to develop into a high state of efficiency the young men of the country. It is felt that the conservation and development of the manhood resources of the country, no less but rather more, than our material resources, are the concern of the whole country.

"Viewed generally, the year just ended has given every evidence of the vast resources of this country, and its ability quickly to adapt and adjust itself to new and changed conditions. Fair harvests, with prices unparallelled for agricultural produce, unequalled activities in our factories, labor enjoying the highest wages of recent times, further substantial increase in the country's favorable trade balance and heavy increase in bank deposits are some of the factors which go to mark 1916 as an abundantly prosperous year in Canada."

New Officers

The following were the representative elections for the ensuing year:

Canadian National Exhibition Association: Messds. G. T. Irving, J. P. Murray, George Brigden, J. S. McKinnon, W. C. Phillips, Sam Harris, E. J. Freyseng, James Litster, T. A. Russell, John Firstbrook, W. C. Coulter and H. N. Cowan.

Representatives to Executive Council: Messrs. George Brigden, J. P. Murray, W. C. Phillips, G. Frank Beer, R. D. Fairbairn, Thomas Findlev, W B.. Tindall, T. F. Monypenny, W. C. Coulter, J. Western, J. S. McKinnon, Sam Harris, Thomas Roden, E. J. Freyseng and R. L. McIntyre.

Branch Executive: Messrs. R. L. McIntyre, W. C. Laidlaw, James Litster, A. H. Jeffrey, F. E. Mutton, S. H. Chapmen, T. F. Monypenny, J. P. Murray, John Hillock, G. B. Clark, John Miller, N. Neilson, J. A. Riordon and F. W. Stone.

The resolution on technical education was moved by J. S. McKinnon, seconded by J. F. Ellis; that on industrial research by W. B. Tindall, seconded by T. F. Monypenny; that on suburban settlement and housing by S. R. Parsons, and seconded by G. Frank Beer.

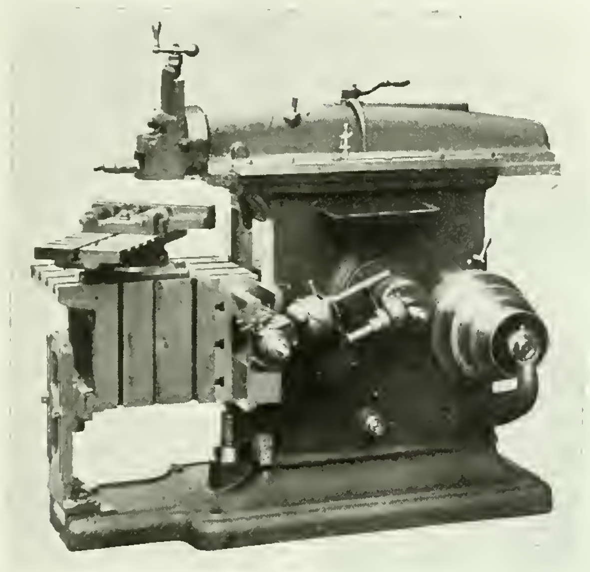
Release Steel for Rails.—Steps are being taken to provide for the rolling of rails required for renewals in Canadian Government railways in Canada. An arrangement will be made with the Imperial Munitions Board, which has first call upon the steel output, for the release of metal for the purpose. The mills at Algoma Steel Co. and Dominion Steel Corporation will be utilized for this work.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

24-IN. HELICAL-GEARED SHAPER

EXPERIMENTS with helical tooth driving gears in shapers have been in progress for several months by the Queen City Machine Co., Cincinnati, Ohio, and as a result it has been decided to make this type of drive standard on their 24-in. machine. This type of gearing operates without noise or backlash, and although a comparatively small helix angle is adopted, 14 deg. 55 min., at least three teeth are in mesh together, resulting in a smooth movement of the ram without any shock.



24-IN. HELICAL-GEARED SHAPER.

The fine finish obtainable on work was largely responsible for the adoption of this drive, the results being only equalled by machine with spiral gear drive; the strength and wearing qualities being greatly increased, while the greatly reduced vibration adds considerably to the life of the machine as a whole.

In addition to this new feature the machine possesses other interesting features, such as heat-treated journals with ring-oiling bearings; the use of semi-steel castings made by the McLain process; quick change feed mechanism, which is fully enclosed and is manipulated without theoperator having to nandle any moving parts.

½ K.W. DOMESTIC LIGHTING AND POWER PLANT

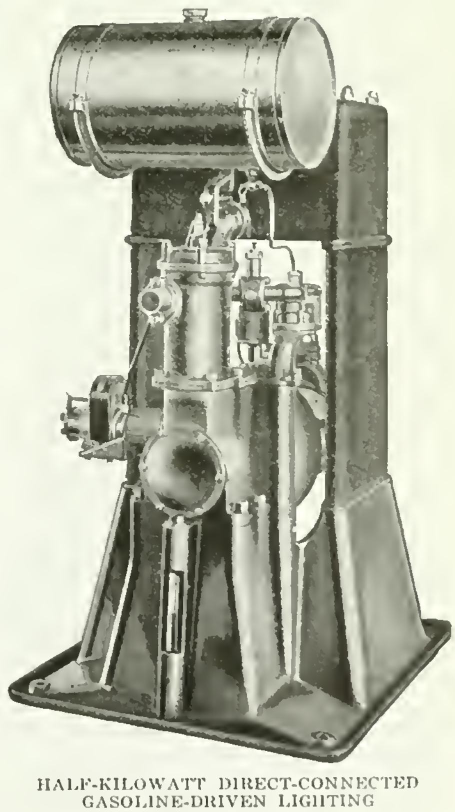
THE problem of designing a home-size lighting plant is one which has engaged the attention of electrical engineers for some time, with varying degress of success. Belt-driven and direct-connected sets with self-starting arrangements, etc., have been available to small power users such as farms, country churches, camps, railroad stations, and isolated inns and boarding houses, but the designs of the set illustrated herewith have made departure from the present tendency by discarding belts, storage batteries and starting devices, and have developed a unit which is claimed to be capable of running continuously night and day if required, the cost of the comparatively idle extra running being less than that of storage battery depreciation.

The engine end of the Uni-Lectric lighting and power plant is shown in the engraving, the rated capacity of the set being 500 watts (½ k.w.) at 110 volts, direct current. A generous overload capacity renders it capable of running fifty 15-watt lamps, or any combined light and power load up to 750 watts, so that two motors of ½ horse-power each may be run from it.

The well-known efficiency of the sleeve-valve type of engine over long periods of continuous operation induced the designers to adopt this principle. The 4 stroke-cycle is employed with a single cylinder of 2¼ in. bore and 3 in. stroke. The sleeve, however, is of the revolving type which thus leaves the piston and piston rod as the only reciprocating parts in the entire construction. The cylinder casting is provided with exhaust and intake ports, and the sleeve which is carefully ground to a proper fit is arranged with two diametrically opposite ports for registration with the cylinder ports. The piston is located inside the sleeve and reciprocates in it as though it were the true cylinder. The sleeve is driven at only one revolution to four revolutions of the crankshaft, its two ports acting alternately as exhaust and intake.

The cylinder, as can be seen, is bolted to the crank case, which carries a single long crank shaft bearing; the armature shaft is tapered and fits into the end of the crank shaft so that it becomes integral therewith, the free or commutator end of the armature shaft being carried in a ball bearing. Forced automatic lubrication by pump is provided to all moving parts except this ball bearing, which only requires attention every month or so.

The entire generator is housed in a casing bolted to the end of crank case, and cooling water hopper and fuel tank are conveniently mounted overhead. Magneto ignition and automatic carburetor and governor are provided, the net weight of the apparatus being 375 lbs., and floor space occupied 24 x 25 in., with a height of 45 in. The Waterman Motor Co., Detroit, Mich., are the builders of this outfit.



HALF-KILOWATT DIRECT-CONNECTED GASOLINE-DRIVEN LIGHTING AND POWER SET.

THE ELECTRIC FURNACE

THE use of the electric iron and steel furnace has made exceptional progress under war conditions. When the demand for steel exceeds the supply, and junk piles are searched for available metal, the electric steel furnace experiences a boom because it is capable of making an excellent quality of steel from a comparatively poor quality of iron and steel scrap. As more and more careful conservation of natural resources becomes necessary, electrical processes steadily gain ground because of their greater economy in the use of raw materials.

At the beginning of 1916 there were 73 electric steel furnaces in the United States producing 100,000 tons per year; to-day there are over double this number with a yearly production exceeding 1,000,000 tons. These furnaces require in the neighborhood of 150,000 h.p., one of the largest single installations having a total capacity of 70 tons in units of 15 and 20 tons.

The relative growth in Canada is even greater; electric furnace steel production has increased from 61 tons in 1915 to 43,790 tons in 1916. In Montreal alone, according to figures supplied by the Civic Investment and Industrial Co., there are in operation, or being installed, 11 electric furnaces requiring a total of 17,000 h.p. The larger furnaces, when fed from high tension lines and properly controlled, offer no serious disturbances to their circuits, but a plant of less than 5,000 h.p. capacity should not attempt to carry single phase furnaces of 400 k.w. or over. The possibilities as an off-peak load are good as the usual length of heat is only about three hours, which condition would adapt itself excellently to a limited service operation. The furnaces can be operated economically at from 1c. to 1½c. per k.w.h., and such rates are now in force in many Canadian centres for ordinary service such as house lighting.

SHIPBUILDING DIFFICULTIES

THE scarcity of steel is given as one reason why any important progress in the development of steel shipbuilding in Canada may have to be deferred. Steel capacity within Canada is largely taken up until the middle of 1918, with the bulk of contracts based on Government requirements in connection with munitions. These contracts may be further enlarged to absorb most of the output for 1919, so, unless any considerable part of the capacity of the mills should be released from munitions on the ground that shipbuilding might be more urgent, the outlook is not encouraging. Even in that event there would be delays until mills to roll ship plates could be equipped.

On the financial side, others see difficulties for an extensive shipbuilding programme in the new Canadian taxation. One large eastern concern is said to have laid aside its plans for a shipbuilding plant on the ground that new capital could not be enlisted in support of such an enterprise, when the risks of loss would have to be heavily scaled down to meet taxes. This, too, is said to be entering as an adverse factor in the plans of some American capital that was coming into the country for the purpose.

DEATH SUMMONS A. R. WILLIAMS

ADVICE of the death of Alfred Ruggles Williams, which occurred on the afternoon of Friday, May 18, at his residence, 56 Madison Avenue, Toronto, after an illness of four days, following a stroke of paralysis, will be received with regret by his many friends and business acquaintances.

The late Mr. Williams, who was widely known as the president of the A. R. Williams Machinery Co., Toronto, with branches at Winnipeg, Man., Vancouver, B.C., and St. John, N.B., was born in Troy, Bradford County, Pa., on December 26, 1838, son of John Wood Williams, of Devonshire, England, and Louise Lee (Ruggles) Williams, of Vermont. Following his education in the public schools of Troy, Pa., and later at a private seminary in Lima, N.Y., he joined his father, who was a farmer and maltster. For conscientious reasons, however, he soon abandoned the career of maltster.

THE LATE ALFRED RUGGLES WILLIAMS.

His first experience of the machinery business, 1862-1868, was gained with the firm of Paterson Bros., Richmond Hill, Ont., in the capacity of traveller; later he assumed management and control of the business. With Robert Thompson he settled at Mitchell, Ont., establishing the foundry business of Thompson & Williams, manufacturers of reapers, mowers, agricultural implements generally, grist and saw mills, steam tractors, etc. In 1875 the plant was removed to Stratford, Ont., a limited liability company being formed under the firm name of The Thompson-Williams Mfg. Co. The nucleus of the present business was organized in Toronto in 1882, being afterwards incorporated in 1894 as the A. R. Williams Machinery Co. The different branches were established as follows: Montreal, 1887; Winnipeg, 1903; Vancouver, 1905; St. John, 1910. Deceased was also a director of Williams & Wilson, machinery dealers, Montreal, and director and vice-president, the Toronto Structural Steel Co.

Mr. Williams' first wife, Mary S. Gould, only daughter of Isaac H. Gould, of Wyoming, N.Y., died in 1903, and is survived by Mary Bartha, wife of Walter H. Clemes, director of the A. R. Williams Co. In 1907 he married Carrie Elinor Baker, of Stratford, Ont., and the two children of the marriage, Alfred Ruggles, jr., and Elinor May, survive.

While resident in Mitchell, Ont., the late Mr. Williams was president of the Public School Board and was active in establishing the High School. Always a stalwart advocate of all benevolent measures and a co-operator in church and temperance work, he took especial interest in the advancement of the Sunday school movement, acting as superintendent of the Central Methodist Sunday School, Toronto, for eighteen years. He was an ex-member of the Sons of Temperance and the Independent Order of Good Templars, and was vice-president of the Committee of One Hundred.

In business life the late Mr. Williams was a member of the Toronto Board of Trade, the Canadian Manufacturers' Association, and the London Association of Commercial Travelers.

The public funeral took place on Monday afternoon, May 21, to Mount Pleasant Cemetery, Toronto. In addition to a private service at deceased's late residence, a public service was held in Central Methodist Church, among those present being the employees of the various A. R. Williams Machinery Co. plants and representatives of a wide variety of social, business and society interests.

MINERAL PRODUCTION FOR THREE MONTHS

THE quarterly report of the Ontario Bureau of Mines covering the records of Ontario's mineral production for the first three months of this year, shows that copper and nickel are running at smelter capacity; gold is being mined in increasing quantity, but silver has dropped in production below the totals for the same period in 1916. Iron ore shows a remarkable increase and considerable increases are also reported in all other items of metalliferous production within the province.

The output of gold was 127,692 ounces, valued at $2,601,760, the Hollinger, Dome and McIntyre camps being the largest producers; 3,945,957 ounces of silver were produced, as against 5,207,831 ounces for the same period in 1916. The value of the silver output was $2.831.873; 10,141 tons of nickel matte and 5,063 tons of copper matte were produced; 52,694 tons of iron ore were mined, as compared with 6,573 tons turned out for the first quarter of last year.

"Willie," said his mother, "I wish you would run across the street asd see how old Mrs. Brown is this morning." A few minuts later Willie returned and reported: "Mrs. Brown says it's none of your business how old she is."

MEN WHOM WE CAN ILL SPARE

FULL of years as the measure of life is reckoned, and hearing alike the respect of those who knew him in a business way and of those to whom contact as a private citizen was vouchsafed, Alfred Ruggles Williams, has passed to the Great Beyond. A record such as his is by no means common, combining as it does business success in a superlative degree, the lack of public honors usually thrust upon men under such circumstances but withal embodying and displaying those attributes of character and adherence to principle and virtue which put the guinea stamp on a man and endear him to his fellows. His business interests, although large and prosperous, and for the most part, therefore, with a tendency to engross his individual attention, never appear during his long life course to have eclipsed or side-tracked the many opportunities always offering for social service, rather will it be found that his interests in the latter direction were equally large and important, and the measurement of achievement equally valuable as those relating particularly to the buying and selling of machinery. The reputation of the A. R. Williams Machinery Co. is front rank, wherever it has transacted business, and it goes without saying that such a circumstance is entirely due to the integrity and sterling worth of its now deceased founder.

Men of Alfred Ruggles Williams' calibre are all too rare in every walk of life, and the loss of one, even although the allotted span has been materially extended in his case, leaves an undesirable gap in the ranks. At any time the work and effort of such men are valuable and fruitful to either a community or a nation, but in times like these, doubly so; as a consequence the passing of but one appeals to us as though he could be ill spared.

MODIFICATION OF WAR TAXATION IN ORDER

JUDGING by the urgent need of ships to replace those sunk and being sunk by enemy submarines and mines, there is great opportunity for the establishment of additional shipbuilding plants in Canada, more especially on her ocean and ocean waterway shores. In previous issues we have urged that advantage be taken of the opportunity offering. Quite a number of shipyards have been projected and a good deal of preliminary work done with reference to them, but there is an apparent tendency for all of them to more or less "hang fire." Lack of Government support, lack of equipment and structural material readily available, and the recent War Tax announcement, are individually and collectively responsible for the hesitancy to take definite action, and on the latter of the three deterrents—the War Tax business profits, there is good reason to believe that considerable onus lies.

The two most important things that must be encouraged in Canada to-day are increased production and increased thrift and saving. The enormous tax which is proposed upon the profits of some incorporated companies, acts as the greatest discouragement to initiative and to production that could well be devised. Business men to-day are prepared to assume heavy burdens and to pay large taxes. Men, however, who are responsible for the investment of money for this cannot assume a responsibility which places upon them the possibility of large losses on the one hand, if unsuccessful, and on the other hand, of only a fraction of the profits gained if the operations are successful. We want to encourage production on the farm to-day. We want to encourage production in the factory. We want to encourage the re-investment in improved plant by manufacturers. We want to encourage the introduction of fresh capital into Canada and the conservation in Canada of her resources.

In this tax on profits the Minister of Finance has gone too far in one direction. He must modify it before it is too late, and if he finds it necessary to replace some revenue which he thinks is going to be lost thereby, then put some tax upon those articles, the consumption of which should be restricted in Canada to-day. Put some tax on the great incomes—ranging from $100,000 to $1,000,000 a year—which are drawn by people who have their investments in bonds and mortgages—much of whose money was made in real estate and other speculation—and who are themselves taking no risk and contributing nothing by their enterprise or ability to production in the country.

Until some material modification of the War Taxation as it applies to business enterprise, established or projected, is made effective, we may look to see not only initiative chilled as regards shipbuilding, but relative to all forms of industry, manufacture, and resources development.

INDUSTRY AND CONSCRIPTION

THE announcement by Sir Robert Borden soon after his return from England that conscription would be resorted to at an early date to maintain the forces of the Dominion at the required strength was not unexpected by observers of events. Chief among such are the manufacturers, especially those in the metal-working industries, and their reception of the announcement has not been such as to occasion grave fears of industrial dislocation and its attendant results.

This last effort is far more likely to affect those strata of society which are unconnected with machine shop interests. The call for labor to carry out the shipbuilding program alone will place a considerable number of manual workers outside the scope. The availability of numbers of women operators due to recent decrease of shell production will in some measure make good the possible drafting of machinists from non-essential trades.

The event should be accepted by the country as final evidence of the seriousness of the war, and if accompanied by reduction of extravagance, and increased production of necessities, with proper control of same, the future results of the present step can be but for the best, industrially, financially and politically.

The General Market Condition and Tendency

THE outlook for manufacturers in regard to their iron and steel requirements is not very promising and indications point to a serious shortage at no distant date. Domestic consumers have for some time experienced considerable difficulty in obtaining steel and have had to wait many weeks for delivery. Now, however, the situation is more acute, as the mills both in Canada and the States are filled up with war orders, which, of course, are taking precedence over all other business. Steel prices, although abnormally high, continue to climb, and the end of the upward movement is not in sight. The congestion at the mills, which is increasing, can have no other effect than to send prices up. Wrought pipe and tubes have again advanced, while higher prices are anticipated on steel plates and sheets, and probably on bars. The demand for ship plates is enormous and extraordinary prices are being paid to secure this material owing to the urgency of the situation. Prices of coal are very firm and dealers state that higher prices are practically certain. The pig-iron situation is unchanged, but an advance is looked for in the near future. The scrap market is quiet, but prices are holding firm, particularly on cast iron and steel scrap. The non-ferrous metal markets are firmer, and indications point to higher prices on copper, tin and lead. The supply business continues active with prices holding firm. The more recent advances include hemp packings and Manila rope. The machine tool business has been quieter this week, but a number of interesting enquiries have been received by local machinery houses.
